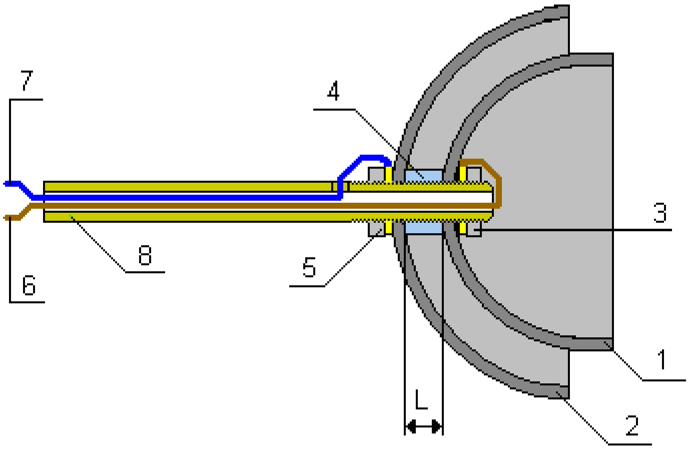
The device is intended to operate on New Zealand's mains supply of 220 volts 50 Hz and a requirement of the apparatus is that it resonates at that 50 Hz frequency. Resonance is a frequent requirement of free-energy systems, and the need for it is often overlooked by people who attempt to replicate free-energy devices. Properly built and tuned, this heater is said to have a COP of 20, which means that twenty times as much heat is produced as would normally be expected from that level of input power. This power gain is caused by additional energy being drawn in from the surrounding environment, and this is very important as a very large percentage of the energy used in cool climates is used for heating, so any reduction would be very welcome.

Peter was granted a New Zealand patent for his heater on 12th December 1944 but he found that opposition from the utility companies was so great that it prevented him from going into commercial production with it and although Peter kept trying for fifty years, he never succeeded.

The device is comprised of a hemispherical resonant cavity, formed by two metallic dome shapes, both of which resonate at 50 Hz. Initially, Peter used two bicycle bells and he found that when submerged in water, the device brought the water to the boil in a very short time indeed. The construction is like this:



If construction were to use two identical hemispheres, then the cavity between them would be anything but even width throughout, but the resonance would be the same. On the other hand, if you want the resonant cavity between the two hemispheres to be of constant width, then the outer hemisphere needs to be markedly larger than the inner hemisphere. The outside of both hemispheres needs to be insulated unless mounted in such a way that it is not possible to touch the hemispheres as both are attached to the mains.

In the diagram shown above, the mains live wire **6**, is fed through the connecting pipe **8**, and clamped to the inner hemisphere **1**, by nut **3** which screws on to the threaded section of tube **8**. It is important that it is the live wire which is connected to hemisphere **1**. The mains neutral wire **7**, is also fed through the connecting tube **8**, then exits through a small hole and is then clamped on to the outside of the outer hemisphere **2**, by nut **5**, also on the threaded section of tube **8**. The two hemispheres are held apart by a spacing washer **4**, which is made from a high-temperature non-conducting plastic. As the tube **8** connects electrically and mechanically to both mains wires through the two locking nuts **3** and **5**, it is essential that this tube is constructed from an electrically non-conducting material such as plastic. as the tube will be in boiling water on a regular basis, it is also necessary that the tube material is able to handle temperatures over 100^{o}C and so possible materials include nylon and Teflon.

The washer is a key component of the heater and it's thickness is key to the efficiency of the whole device. This thickness **L**, is the tuning control for the cavity. The outer hemisphere is about 8 mm greater in diameter than the diameter of the inner hemisphere. Allowing for the thickness of the metal of the bowl, the resonant cavity will therefore be about 3 mm or one eighth of an inch.

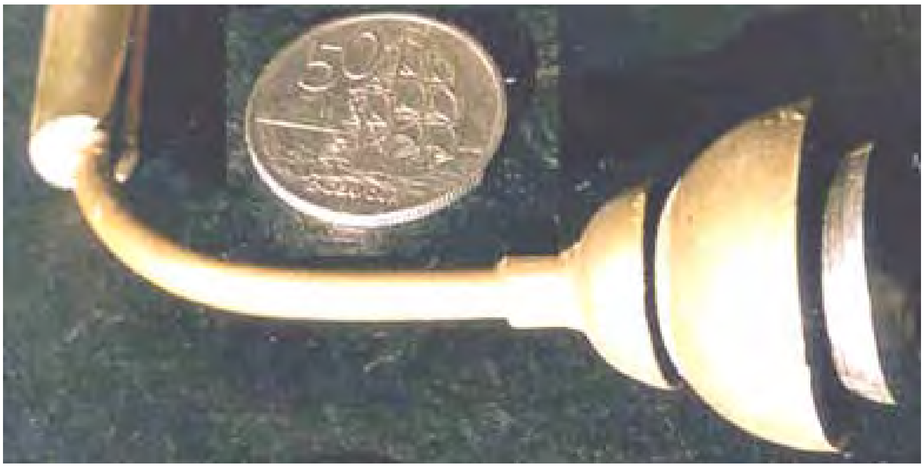
The hemisphere **1** is also tuned to 50 Hz by grinding it carefully until it resonates freely at that frequency. Connecting a loudspeaker in series with a resistor of say, 100K ohms, will give a sound of the exact frequency with which this hemisphere needs to resonate. This tuning needs to be done with the unit fully assembled as the connections to the tube will alter the resonant frequency of the hemisphere. When this is being done, the resonance will be felt rather than heard, so hold the tube lightly so that it can resonate freely. The tuning is done by removing a small amount of metal from the face of hemisphere **1** and then testing for resonance again.

When hemisphere **1** resonates well at the mains frequency, (roughly G two octaves below middle C on a keyboard), the search for high-efficiency heating is carried out by very small adjustments of the gap **L**. The adjustment of the gap **L** is carried out by very careful grinding down of the separating washer **4** and the result is best determined by measuring the length of time needed to boil a known volume of water and the current taken to do that. Repeated tests and recorded results, shows when the best gap has been reached and the highest efficiency achieved. The heater can, of course, be used to heat any liquid, not just water.

This heater is unlike a standard kettle heating element. In the standard method, the water is not a part of the main current-carrying circuit. Instead, the mains power is applied to the heater element and the current flowing through the heater element causes it to heat up, and the heat is then conveyed to the water by conduction. In Davey's heater, on the other hand, the current flow appears to be through the water between the two hemispheres. It seems likely that the actual heating is not produced by current flow at all, but from cavitation of the water caused by the resonating of the cavity between the two hemispheres. This technique is used in small jewellery cleaners where and audio frequency is applied to a cleaning fluid in a small container.

A small amount of electrolysis will take place with the Davey heater as it in effect also forms a single parallel-connected electrolyser. The amounts should be very small as only 1.24 volts out of the 220 volts applied will be used in the electrolysis process.

An early construction of the original heater is shown in the photograph below. The coin shown in the picture is 32 mm (1.25 inch) in diameter. The heater is submerged in water when it is being used, and it brings that water to the boil exceptionally quickly. The unit was tested by New Zealand scientists who were able to vouch for its performance, but who were unable to state exactly how its operation allowed it to output such a high level of heat for such a low level of electrical input. You will notice from the photograph, how carefully the electrical connections and outer bowl are insulated.

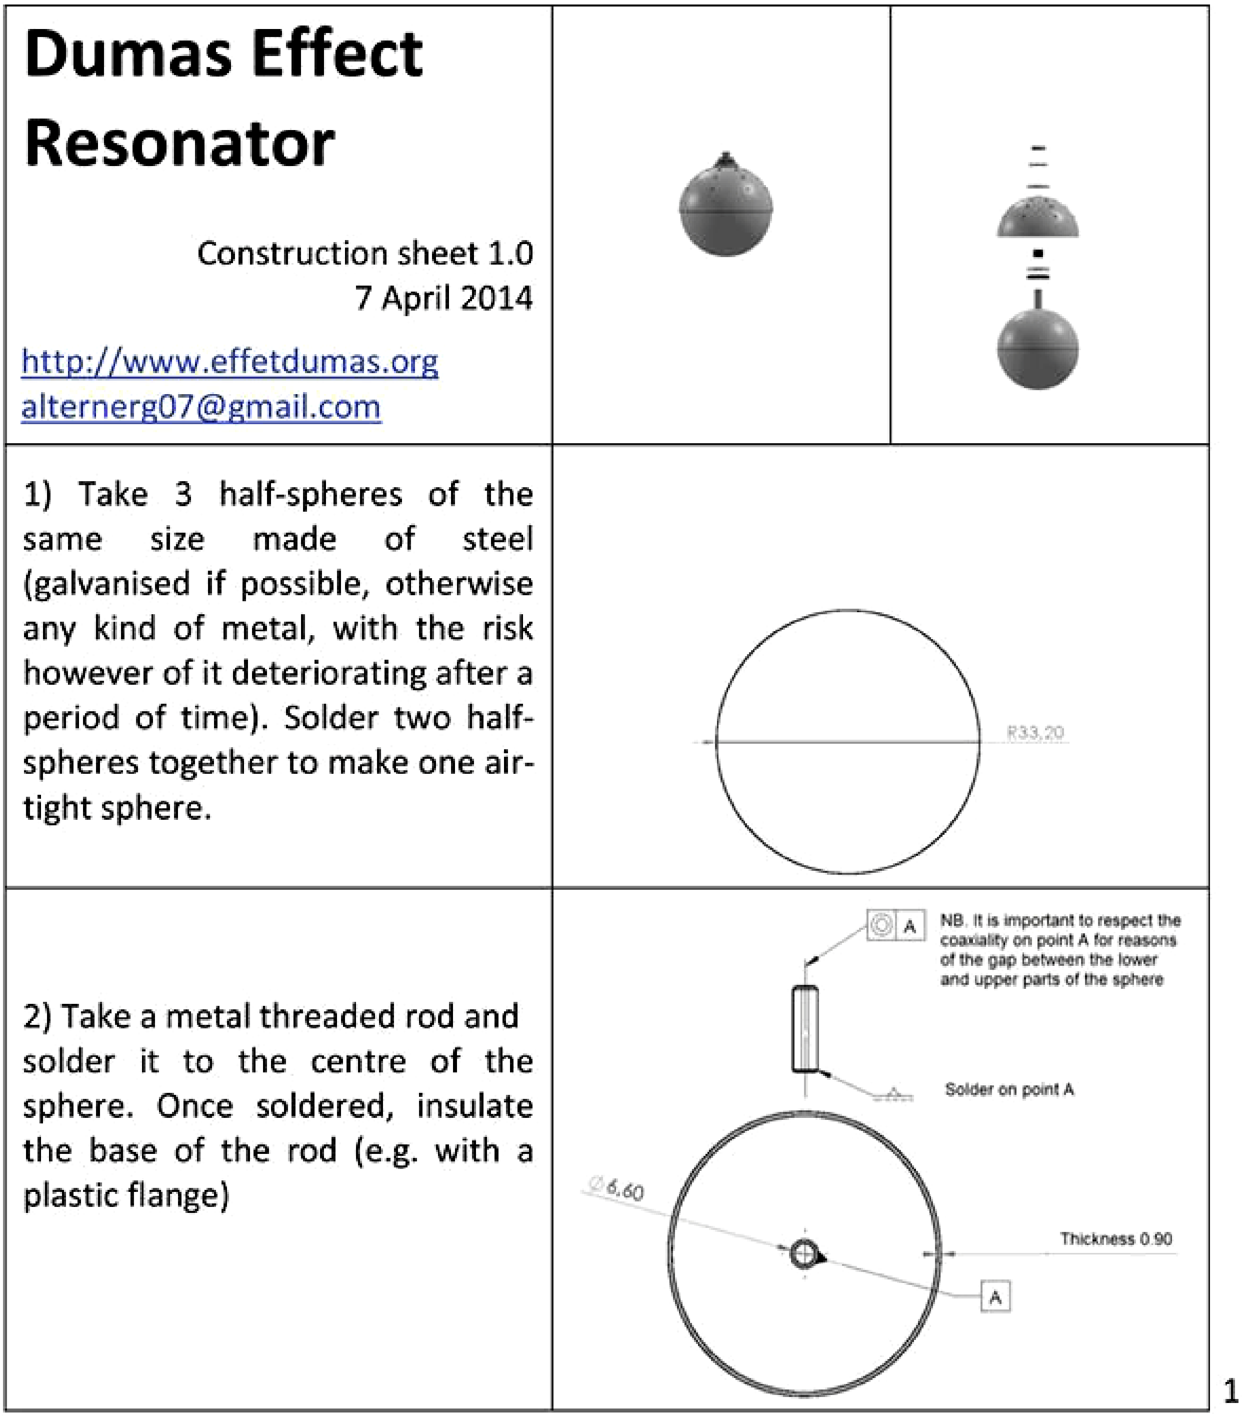


The original prototype which Peter made was constructed from the tops of two bicycle bells, only one of which was tuned to 50 Hz. This shows that the device will definitely work if the inner hemisphere is tuned correctly. You can find forum investigation at http://www.overunity.com/index.php?topic=4083.msg86151;topicseen and more recent information at http://merlib.org/node/5504.

Jean-Christophe Dumas

A Frenchman, Jean-Christophe Dumas, publicises his COP=1.17 heater design which appears to operate in a very similar way to that of Peter Davey. His website at http://leblogdejc.com/effetdumas/?page_id=165 gives an English translation of much of what he has to say.

In this design, steam is produced almost immediately after some 500 watts of input power is applied. He uses a metal sphere plus one metal hemisphere which has an adjustable spacing over half of the sphere's surface. Jean-Christophe wishes to share his design freely with everybody and he sees it as being used for efficient space heating in houses, given a radiator system. His drawings are:



Dumas Effect Resonator

Construction sheet 1.0

alternerg07@gmail.com

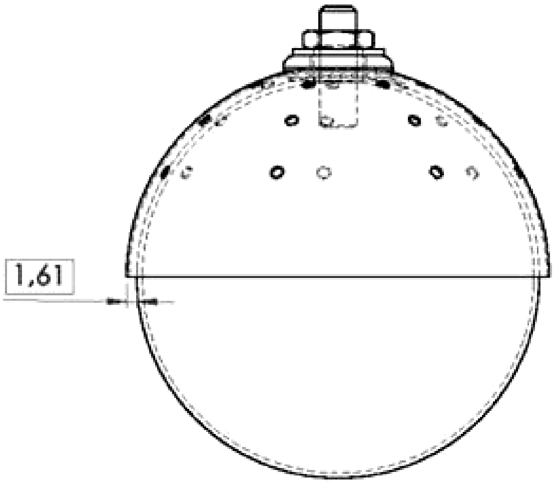
1) Take 3 half-spheres of the same size made of steel (galvanised if possible, otherwise any kind of metal, with the risk however of it deteriorating after a period of time). Solder two half-spheres together to make one air-tight sphere.

2) Take a metal threaded rod and solder it to the centre of the sphere. Once soldered, insulate the base of the rod (e.g. with a plastic flange)

NB. It is important to respect the coaxiality on point A for reasons of the gap between the lower and upper parts of the sphere

1

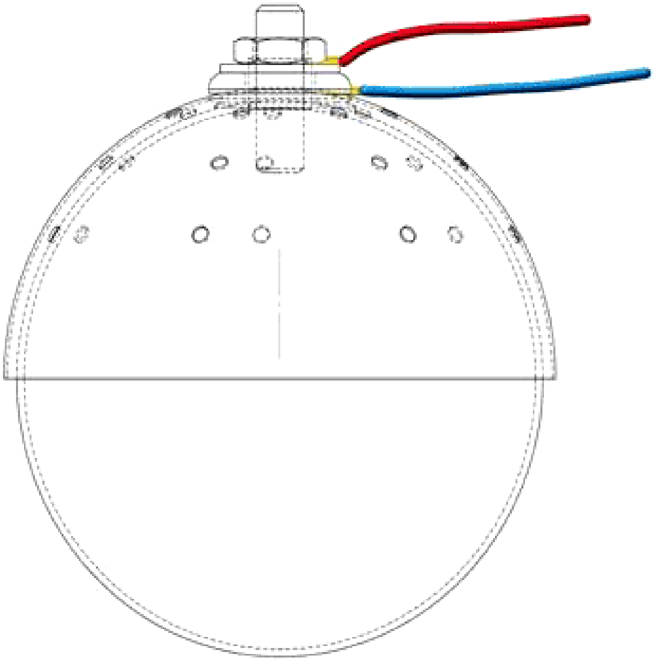
3) Drill a hole in the centre of the remaining half-sphere the size of the rod (possibly increased to fit the thickness of the insulation). Drill a maximum of 20 more holes with a diameter of 2 mm, so that the sphere looks like a sieve.	 NB. This is a series of 7 lines of 3 holes with diameters of 2 mm
4) Place 2 x 2 mm plastic washers at the base of the soldered rod on the sphere, drill the half-sphere in the centre and adjust the gap to about 1.6-1.7 mm (For perfect precision, it would be ideal to create the spheres using a 3D printer)	
5) Screw a nut on the rod and adjust the gap between the upper half-sphere and lower part of the sphere to obtain an ideal gap of 1.61 mm (golden section). If the gap is much less (0.6 to 0.9 mm) there will be a short-circuit. If it is more than 1.8 to 1.9 mm, it will not produce any effet.

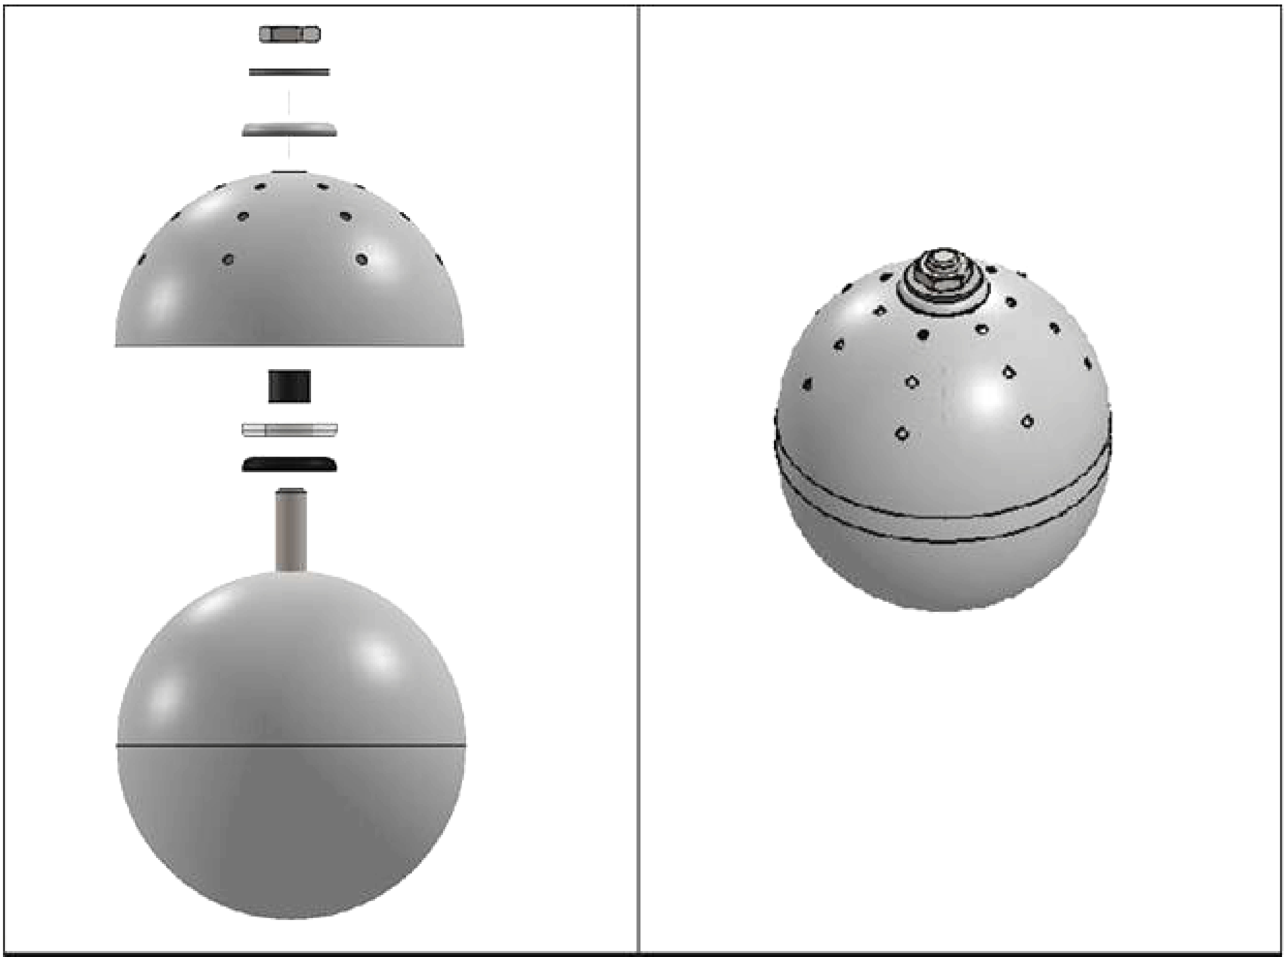


6) Connect an electrical live wire (16A) to the top of the rod soldered on the sphere.

7) As shown in the drawing, connect the 2nd neutral wire (16A) to obtain direct contact on the upper half-sphere by means of a ring or spade connector.

8) Attach a switch to the wires and join the electrical wires to an ordinary electric switch made safe with a residual circuit breaker.





WARNING: The assembly of this process is for scientific experiments and offers the possibility of numerous appliations: water heater, domestic heating, production of drinking water, production of electricity by energy surplus, etc.) It must be done by a professional or a handyman experienced in handling electrical appliances. This process shows several physical effects that are still largely unknown. The inventor declines all responsibility for misuse of this application. NEVER TOUCH THE APPLIANCE WHILE IT IS WORKING, OR THE WATER, OR THE JAR (risk of burns and/or electrocution). Never carry out the experiment alone. Make sure you have a secure environment in case of short circuits, as well as protective gear (masks, gloves). There is a risk being splashed by boiling water or steam, or possible release of flammable gases (oxygen, hydrogen). JC Dumas

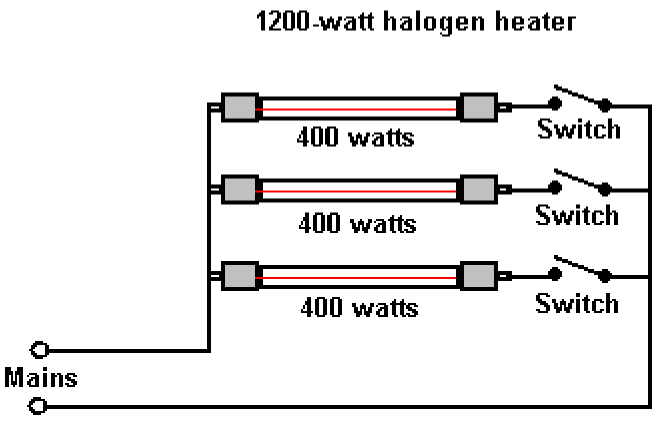
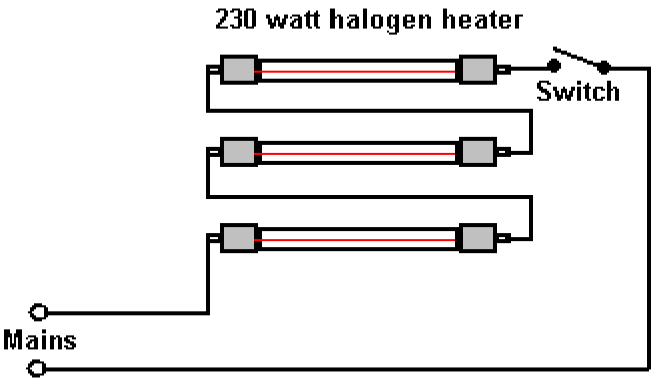
The Series-connected Heater.

While not a free-energy device, one simple arrangement which I use myself, is an adapted halogen heater. A standard, low-cost halogen heater consists of three separate 400-watt sections with a switching arrangement which allows one, two or three sections to be powered up:



1200-watt halogen heater
400 watts
Switch
400 watts
Switch
400 watts
Switch
Mains

I changed the connections inside my particular heater, so that all three halogen lamps are connected in a chain. This did not involve cutting any wires or making any new connections as the wires connecting to the lamps have push-on 'spade' connectors to allow for both simple manufacturing and easy replacement of a halogen lamp. The new arrangement is like this:



230 watt halogen heater
Switch
Mains

This arrangement 'under-runs' the lamps as each lamp only gets one third of the voltage which it was designed for. This has the effect of increasing the working life of the lamp enormously. You would expect the heat output to be very poor, and perhaps it is. But it gives the impression of being quite effective and with all of the three sections working, it provides a gentle heat and light which seems very effective in keeping a room warm.

The Home Power, Home-Build Wind-Powered Electrical Generator.

Here is an interesting article from the Home Power web site. If you are interested in renewable power, then I strongly recommend that you visit their web site http://www.homepower.com and consider subscribing to their magazine as they cover many practical topics using simple wording. Here is an example of the high quality material from Home Power – a 100 watt wind generator built from scratch in just one day:

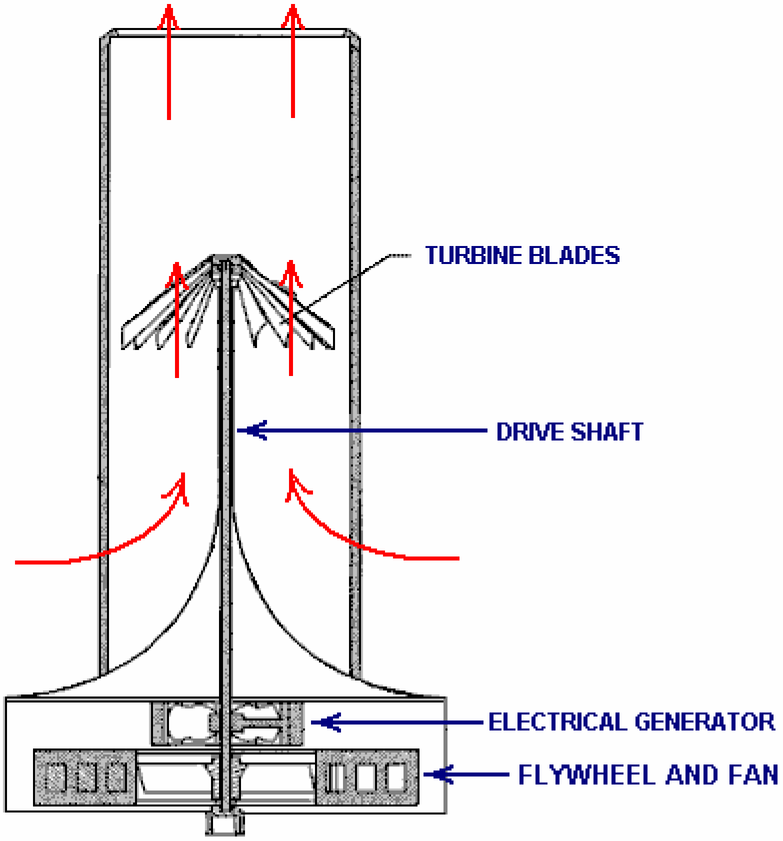
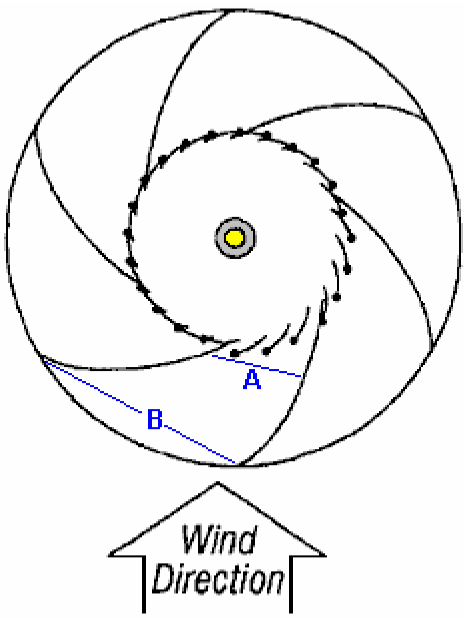
William McDavid's Wind-Powered Generator.

William McDavid junior remarks that a horizontal axis windmill of that type creates an area of slow-moving air behind the blades and that restricts the flow of air past the blades. A way to overcome that is to project the outgoing air in a direction which does not impede the incoming air. He shows how this can be done in his patent US Patent 6,800,955 of 5th October 2004. In this design, the wind blows into the generator housing and is deflected upwards through the fan blades of a turbine which spins an electrical generator:



One clever feature common to both of these designs is the use of a stationary circular housing with deflectors which uses the wind flow no matter what the wind direction happens to be at any given moment. Looking down from above, the housing looks like this:



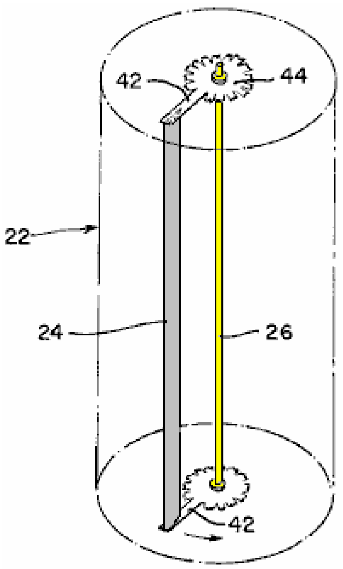
This view shows two important features which enhance the performance of the device. The first is that hinged flaps allow the (horizontal) inflow of air but block the air from flowing straight out of the other side of the central section. This forces the wind to turn and flow upwards, and not only that, but this arrangement causes the air to spin, creating a miniature tornado vortex which amplifies the power of the wind as can be seen from the devastation caused by full-size tornadoes in the environment. As can be seen from the upper diagram, an upward-curving conical piece on the base of the housing assists the airflow to turn upwards as it spins. The spinning air helps to spin the generator blades faster, giving additional power.

A major additional feature is the fact that the dimension "**A**" is considerably less than the dimension "**B**" due to the reduced diameter of the housing nearer the centre. This means that the air flowing past the vanes of housing gets squeezed into a smaller space as it flows. This forces the air to speed up, causing the flow inside the central housing to be higher than the wind-speed outside and that boosts the performance of the device. This wind-powered generator looks like a straightforward project for home construction and with the air being deflected vertically, there does not appear to be any reason why several should not be located near each other. William's full patent can be seen in the appendix of this eBook.

Frank Herbert's Wind-Powered Generator.

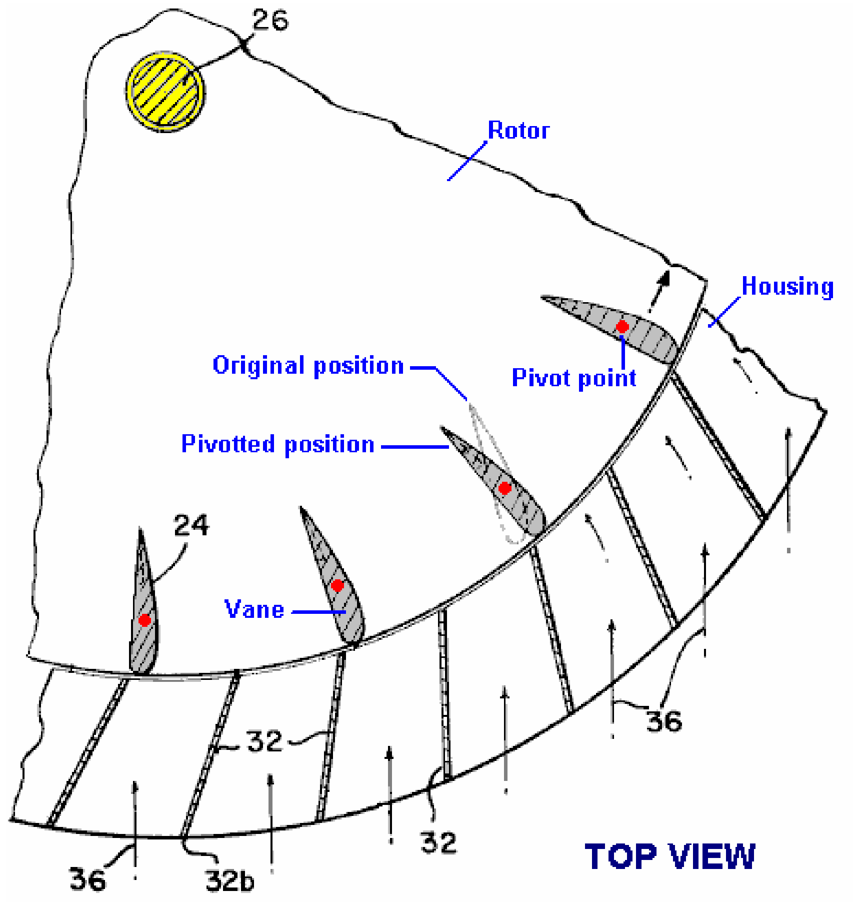
As has been carefully explained by the above article, if a windmill of the blade variety is mounted low down then it is dangerous, and people on sailing boats have been killed by them. Also, if the blade arrangement is designed to operate well in low wind conditions, then it is not unusual for there to be a problem if the wind rises to gale force or higher, with some generator designs giving up and switching off entirely, even though the available free energy is at its highest level.

This design by Frank Herbert is perfectly capable of being home-built and yet it overcomes these problems as well as being a high-efficiency wind turbine. It has an outside cage which prevents human access to the moving parts inside and the 'cage' is not just for protection but is there to enhance the performance of the device. In passing, windmills can be used to compress air and compressed air cylinders can be used to power vehicles and/or power electrical generators during periods of heavy power requirements. The following information is from Frank Herbert's US Patent 4,142,822 of 1979:



The vertical housing **22** shown dotted here, surrounds the vertical power take-off shaft **26**. The wind is allowed to flow through this housing at any angle, so there is no need for the housing to move. In the diagram above small discs **44** are shown at each end of the vertical shaft. These discs have arms **42** extending outwards to support a series of vertical vanes or pressure surfaces **24**. For clarity, just one vane is shown through there will actually be many of these (rather like the cutting blades on a cylinder lawnmower). In reality, there will be no arms on the discs **42** as it is much easier just to have a full-width solid disc supporting the vanes.

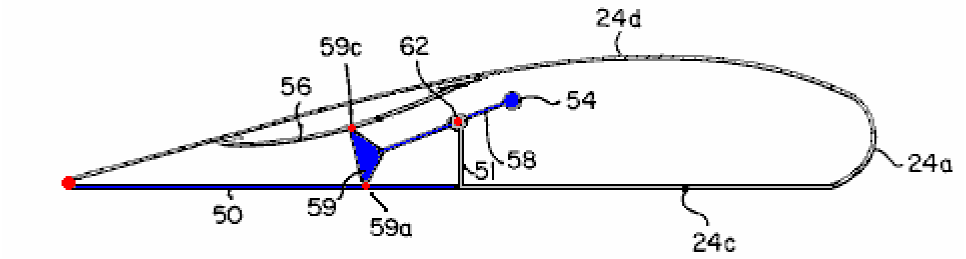
The outer housing has a series of vertical slats which are angled to direct the incoming wind on to the vanes at the best possible angle:



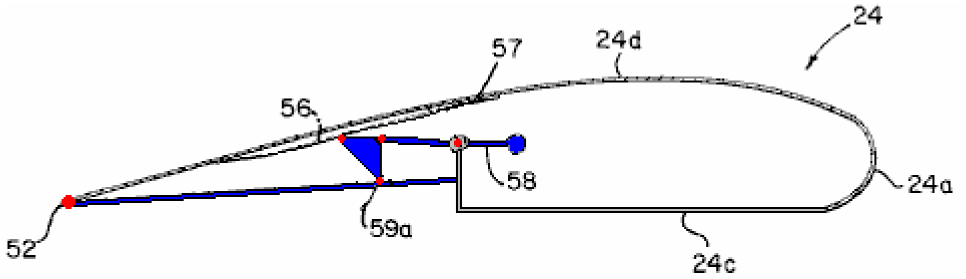
This top view of part of the device, shows the main mounting shaft **26** on which the top and bottom rotor discs are mounted. The red dots show the pivot points where the vanes **24** can turn to take the greatest advantage of the wind pressure. The incoming wind **36**, is deflected by the slats of the housing **32**, to give it a good angle when flowing through the device as well as keeping humans away from the spinning mechanism. As the vanes and slats are located all the way around shaft **26**, sudden changes in wind direction and/or wind strength have no particular effect on this design as it operates with wind coming from any direction and no physical movement of any part of the device is needed for a change in wind direction.

The vanes can have various different profiles and still work well. The shape shown above is the shape of an aircraft wing, where a force acting towards the curved surface is generated when air flows around the shape. This is not a particularly difficult shape to construct and it is very effective in an airflow (which is why it is used to lift aircraft off the ground). There can be any convenient number of vanes and a device built as shown above should be very effective..

As the overall efficiency is improved if there is no turbulence inside the device, Frank has found a method of minimising this. For this, he uses a mechanism which can alter the shape of the vanes when the wind speed gets high. The higher wind speed whirls the vanes around faster, causing higher 'centrifugal' forces on the vanes which Frank uses as follows. Weight **54** gets pushed across by the spin rate of the rotor.



This pushes against the spring **56**, compressing it. The triangle link **59** moves upwards, pivoting at points **59a** and **59c**, and raising section **50** of the vane. This changes the shape of the vane as shown here:



The result of this changed shape is to reduce turbulence inside the device and raise the overall efficiency.

The Mead and Holmes Power System.

The US patent 4,229,661 dated 1980 from Claude Mead and William Holmes is entitled "Power Plant for Camping Trailer" proposes the use of a wind power generator to store compressed air for later use in providing household electrical current, and simultaneously charge batteries which can be used to drive the compressor in periods of very high electrical demand. There is also an option for a rapid system charge if AC mains power becomes available:

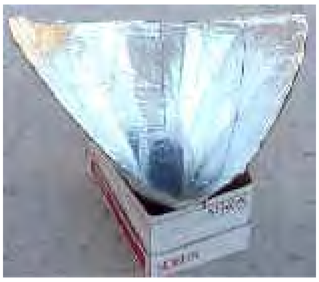
The Solar Funnel Cooker

How to Make and Use The Brigham Young University Solar Cooker/Cooler

by Professor of Physics at Brigham Young University (BYU), with Colter Paulson, Jason Chesley, Jacob Fugal, Derek Hullinger, Jamie Winterton, Jeannette Lawler, and Seth, David, Nathan, and Danelle Jones.



Introduction

A few years ago, I woke up to the fact that half of the people in the world must burn wood or dried dung in order to cook their food. It came as quite a shock to me, especially as I learned of the illnesses caused by breathing smoke day in and day out, and the environmental impacts of deforestation - not to mention the time spent by people (mostly women) gathering sticks and dung to cook their food. And yet, many of these billions of people live near the equator, where sunshine is abundant and free. So.....

As a University Professor of Physics with a background in energy usage, I set out to develop a means of cooking food and sterilising water using the energy freely available from the sun. First, I looked at existing methods.

The parabolic cooker involves a reflective dish which concentrates sunlight to a point where the food is cooked. This approach is very dangerous since the sun's energy is focused to a point which is very hot, but which cannot be seen. (Brigham Young University students and I built one which will set paper on fire in about 3 seconds!). I learned that an altruistic group had offered reflecting parabolas to the people living at the Altiplano in Bolivia. But more than once these parabolas had been stored next to a shed -- and the passing sun set the sheds on fire! The people did not want these dangerous, expensive devices, even though the Altiplano region has been stripped of fuel wood.

The box cooker: Is basically an insulated box with a glass or plastic lid, often with a reflecting lid to direct sunlight into the box. Light enters through the top glass (or plastic), to slowly heat up the box. The problems with this design are that energy enters only through the top, while heat is escaping through all of the other sides, which have a tendency to draw heat away from the food. When the box is opened to put food in or take it out, some of the heat escapes and is lost. Also, effective box cookers tend to be more complicated to build than the funnel cooker.

While studying this problem, I thought again and again of the great need for a safe, inexpensive yet effective solar cooker. It finally came to me at Christmastime a few years ago, a sort of hybrid between the parabola and the box cooker. It looks like a large, deep funnel, and incorporates what I believe are the best features of both the parabolic cooker and the box cooker.

The first reflector was made at my home out of aluminium foil glued on to cardboard, then this was curved to form a reflective funnel. My children and I figured out a way to make a large cardboard funnel easily. (I'll tell you exactly how to do this later on.)

The Solar Funnel Cooker is safe and low cost, easy to make, yet very effective in capturing the sun's energy for cooking and pasteurising water -> Eureka!

Later, I did extensive tests with students (including reflectivity tests) and found that aluminised Mylar was good too, but relatively expensive and rather hard to come by in large sheets. Besides, cardboard is found throughout the world and is inexpensive, and aluminium foil is also easy to come by. Also, individuals can make their own solar cookers easily, or start a cottage-industry to manufacture them for others.

Prototypes of the Solar Funnel Cooker were tested in Bolivia, and outperformed an expensive solar box cooker and a “Solar Coolkit” while costing much less then either. Brigham Young University submitted a patent application, mainly to insure that no company would prevent wide distribution of the Solar Funnel Cooker. Brigham Young University makes no profit from the invention. (I later learned that a few people had had a similar idea, but with methods differing from those developed and shown here). So now I'm trying to get the word out so that the invention can be used to capture the free energy coming from the sun - for camping and for emergencies, yes, but also for every day cooking where electricity is not available and where even fuel wood is getting scarce.

How it Works

The reflector is shaped like a giant funnel, and lined with aluminium foil. (Easy to follow instructions will be given soon). This funnel is rather like the parabolic cooker, except that the sunlight is concentrated along a line (not a point) at the bottom of the funnel. You can put your hand up the bottom of the funnel and feel the sun's heat, but it will not burn you.

Next, we paint a jar black on the outside, to collect heat, and place this at the bottom of the funnel. Or a black pot with a lid can be used. The black vessel gets hot, quickly, but not quite hot enough to cook with. We need some way to build up the heat without letting the outside air cool it. So, I put a cheap plastic bag around the jar -- and, the solar funnel cooker was born! The plastic bag, available in grocery stores as a "poultry bag", replaces the cumbersome and expensive box and glass lid of solar box ovens. You can use the plastic bags used in American stores to put groceries in, as long as they let a lot of sunlight pass. (Dark- coloured bags will not do).

I recently tested a bag used for fruits and vegetables, nearly transparent and available free at American grocery stores, that works great. This is stamped "HDPE" for high-density polyethylene on the bag (ordinary polyethylene melts too easily). A block of wood is placed under the jar to help hold the heat in. (Any insulator, such as a hot pad or rope or even sticks, will also work).

A friend of mine who is also a Physics Professor did not believe I could actually boil water with the thing. So I showed him that with this new "solar funnel cooker" I was able to boil water in Utah in the middle of winter! I laid the funnel on its side since it was winter and pointed a large funnel towards the sun to the south. I also had to suspend the black cooking vessel -- rather than placing it on a wooden block. This allows the weaker sun rays to strike the entire surface of the vessel.

Of course, the Solar Funnel works much better outside of winter days, that is, when the UV index is 7 or greater. Most other solar cookers will not cook in the winter in northern areas (or south of about 35 degrees, either).

I thought that a pressure cooker would be great. But the prices in stores were way too high for me. Wait, how about a canning jar? These little beauties are designed to relieve pressure through the lid -- a nice pressure cooker. And cooking time is cut in half for each 10ºC we raise the temperature (Professor Lee Hansen, private communication). I used one of my wife's wide-mouth canning jars, spray-painted (flat) black on the outside, and it worked great. Food cooks faster when you use a simple canning jar as a pressure cooker. However, you can also put a black pot in the plastic bag instead if you want. But don't use a sealed container with no pressure release like a mayonnaise jar -- it can break as the steam builds up (I've done it)!

How to Build Your Own Solar Funnel Cooker

What You will Need for the Funnel Cooker:

A piece of flat cardboard, about 2 feet wide by 4 feet long. (The length should be just twice the width. The bigger, the better).

Ordinary aluminium foil.

A glue such as white glue (like Elmer's glue), and water to mix with it 50-50. Also, a brush to apply the glue to the cardboard (or a cloth or paper towel will do). Or, some may wish to use a cheap "spray adhesive" available in spray cans. You can also use flour paste.

Three wire brads - or small nuts and bolts, or string to hold the funnel together.

For a cooking vessel, I recommend a canning jar ("Ball" wide-mouth quart jars work fine for me; the rubber ring on the lid is less likely to melt than for other jars I've found. A two-quart canning jar is available and works fine for larger quantities of food, although the cooking is somewhat slower).

The cooking jar (or vessel) should be spray-painted black on the outside. I find that a cheap flat-black spray paint works just fine. Scrape off a vertical stripe so that you have a clear glass "window" to look into the vessel, to check the food or water for boiling.

A block of wood is used as an insulator under the jar. I use a piece of 2" x 4" board which is cut into a square nominally 4" x 4" by about 2" thick. (100 mm square x 50 mm thick). One square piece of wood makes a great insulator.

A plastic bag is used to go around the cooking-jar and block of wood, to provide a green-house effect. Suggestions:

- Reynolds™ Oven Bag, Regular Size works great: transparent and won't melt. (Cost about 25 cents each in U.S. grocery stores.)

- Any nearly-transparent HDPE bag (High-density Polyethylene). Look for "HDPE" stamped on the bag. I've tested HDPE bags which I picked up for free at my grocery store, used for holding vegetables and fruits. These are thin, but very inexpensive. Tested side-by-side with an oven bag in two solar funnels, the HDPE bag worked just as well! **Caution:** we have found that some HDPE bags will melt should they contact the hot cooking vessel. For this reason, we recommend using the oven-safe plastic bag wherever possible.

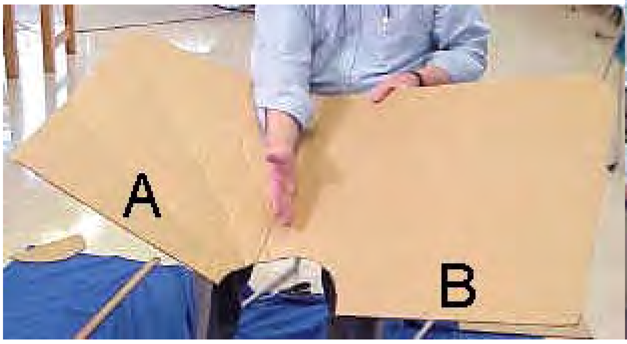
- An idea attributed to Roger Bernard and applied now to the BYU Funnel Cooker: place a pot (having a blackened bottom and sides) in a glass bowl, and cover with a lid. Try for a tight fit around the bottom to keep hot air trapped inside. The metal pot or bowl should be supported around the rim only, with an air space all around the bottom (where the sunlight strikes it). Put a blackened lid on top of the pot. Then simply place this pot-in-bowl down in the bottom of the funnel - no plastic bag is needed! This clever method also allows the cook to simply remove the lid to check the food and to stir. I like this idea - it makes the solar cooker a lot like cooking over a fire. See Photographs for further details.

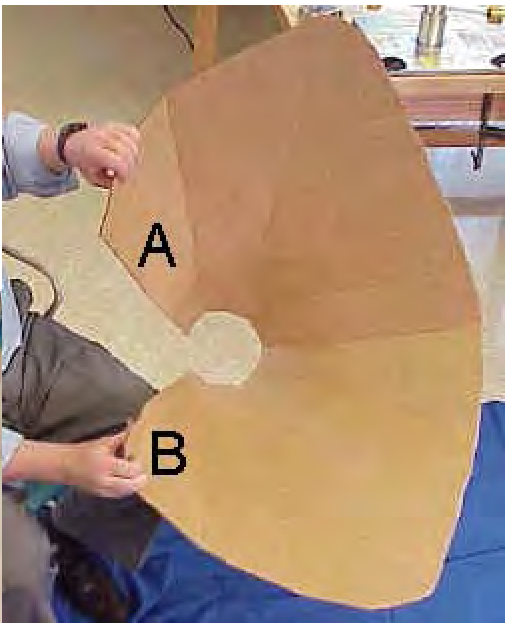
Construction Steps

Cut a Half-circle out of the Cardboard

Cut a half circle out of the cardboard, along the bottom as shown below. When the funnel is formed, this becomes a full-circle and should be wide enough to go around your cooking pot. So for a 7" diameter cooking pot, the radius of the half-circle is 7". For a quart canning jar such as I use, I cut a 5" radius half-circle out of the cardboard.

Form the Funnel



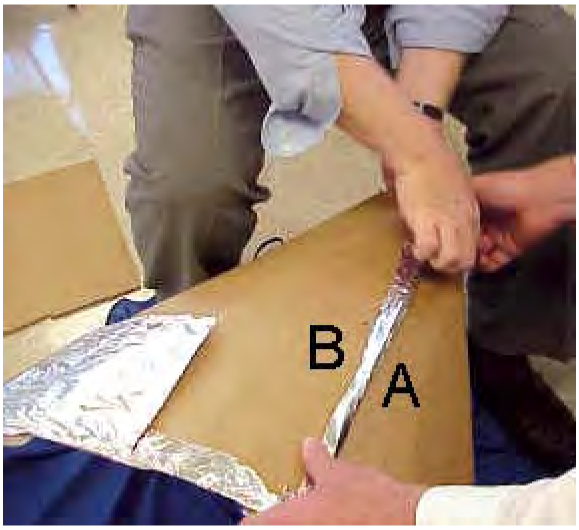


To form the funnel, you will bring side A towards side B, as shown in the figure. The aluminium foil must go on the INSIDE of the funnel. Do this slowly, helping the cardboard to the shape of a funnel by using one hand to form creases that radiate out from the half-circle. Work your way around the funnel, bending it in stages to form the funnel shape, until the two sides overlap and the half-circle forms a complete circle. The aluminium foil will go on the INSIDE of funnel. Open the funnel and lay it flat, "inside up", in preparation for the next step.

Glue Foil to Cardboard

Apply glue or adhesive to the top (inner) surface of the cardboard, then quickly apply the aluminium foil on top of the glue, to affix the foil to the cardboard. Make sure the shiniest side of the foil is on top, since this becomes your reflective surface in the Funnel. I like to put just enough glue for one width of foil, so that the glue stays moist while the foil is applied. I also overlap strips of foil by about 1" (or 2 cm). Try to smooth out the aluminium foil as much as you reasonably can, but small wrinkles won't make much difference. If cardboard is not available, one can simply dig a funnel-shaped hole in the ground and line it with a reflector, to make a fixed solar cooker for use at mid-day.

Join side A to side B to keep the funnel together.



The easiest way to do this is to punch three holes in the cardboard that line up on side A and side B (see figure). Then put a metal brad through each hole and fasten by pulling apart the metal tines. Or you can use a nut-and-bolt to secure the two sides (A & B) together.

Be creative here with what you have available. For example, by putting two holes about a thumb-width apart, you can put a string, twine, small rope, wire or twist-tie in one hole and out the other, and tie together.

When A and B are connected together, you will have a "funnel with two wings". The wings could be cut off, but these help to gather more sunlight, so I leave them on.

Tape or glue a piece of aluminium foil across the hole at the bottom of the funnel, with shiny side in.

This completes assembly of your solar funnel cooker.

For stability, place the funnel inside a cardboard or other box to provide support. For long-term applications, one may wish to dig a hole in the ground to hold the Funnel against strong winds.

Final Steps

At this stage, you are ready to put food items or water into the cooking vessel or jar, and put the lid on securely. (See instructions on food cooking times, to follow).

Place a wooden block in the INSIDE bottom of the cooking bag. I use a piece of 2” x 4” board which is cut into a square nominally 4" x 4" by 2" thick. Then place the cooking vessel containing the food or water on top of the wooden block, inside the bag.

Next, gather the top of the bag in your fingers and ***blow air into the bag, to inflate it***. This will form a small "greenhouse" around the cooking vessel, to trap much of the heat inside. Close off the bag with a tight twist tie or wire. Important: the bag should not touch the sides or lid of the cooking vessel. The bag may be called a "convection shield," slowing convection-cooling due to air currents.

Place the entire bag and its contents inside the funnel near the bottom as shown in the Photographs.

Place the Solar Funnel Cooker so that it Faces the Sun

Remember: Sunlight can hurt the eyes: so please wear sunglasses when using a Solar Cooker! The Funnel Cooker is designed so that the hot region is deep down inside the funnel, out of harm's way.

Put the Solar Funnel Cooker in the sun pointing towards the sun, so that it captures as much sunlight as possible. The design of the funnel allows it to collect solar energy for about an hour without needing to be re-positioned. For longer cooking times, readjust the position of the funnel to follow the sun's path.

In the Northern Hemisphere, it helps to put the Solar Funnel Cooker in front of a south-facing wall or window as this reflects additional sunlight into the funnel. A reflective wall is most important in locations farther from the equator and in winter. In the Southern Hemisphere, put the Solar Funnel Cooker in front of a North-facing wall or window to reflect additional sunlight into your cooker.

After Cooking

Remember that the cooking vessel will be very hot: so use cooking pads or gloves when handling it! If you are heating water in a canning jar, you may notice that the water is boiling when the lid is first removed - it gets very hot!

Open the plastic cooking bag by removing the twist-tie. Using gloves or a thick cloth, lift the vessel out of the bag and place it on the ground or table. Carefully open the vessel and check the food, to make sure it has finished cooking. Let the hot food cool before eating.

Helpful Hints

Avoid leaving fingerprints and smudges on the inside surface of the cooker. Keep the inner surface clean and shiny by wiping occasionally with a wet towel. This will keep the Solar Funnel Cooker working at its best.

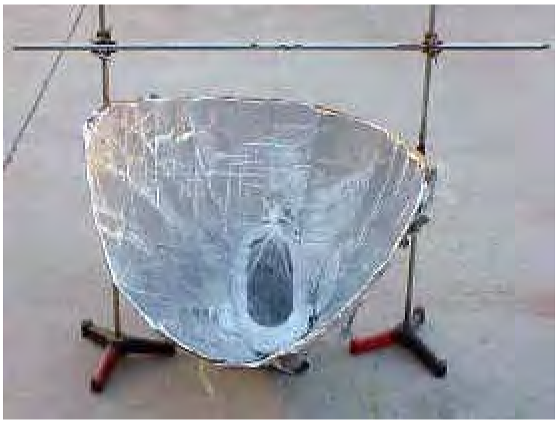
If your funnel gets out-of-round, it can be put back into a circular shape by attaching a rope or string between opposite sides which need to be brought closer together.

For long-term applications, a hole in the ground will hold the Funnel Cooker securely against winds. Bring the funnel inside or cover it during rain storms.

The lids can be used over and over. We have had some trouble with the rubber on some new canning-jar lids becoming soft and "sticky." "Ball canning lids" do not usually have this problem. Running new lids through very hot water before the first use seems to help. The lids can be used over and over if they are not bent too badly when opened (pry off lid carefully).

The jar can be suspended near the bottom of the funnel using fishing line or string (etc.), instead of placing the jar on a block of wood. A plastic bag is placed around the jar with air puffed inside, as usual, to trap the heat. The suspension method allows sunlight to strike all surfaces of the jar, all around, so that heats faster and more evenly. This suspension method is crucial for use in winter months.

Adjust the funnel to put as much sunlight onto the cooking jar as possible. Look at the jar to check where the sunlight is hitting, and to be sure the bottom is not in the shadows. For long cooking times (over about an hour), readjust the position of the funnel to follow the sun's path. During winter months, when the sun is low on the horizon (e.g., in North America), it is helpful to lay the funnel on its side, facing the sun.



Tests in Utah

I have personally used the Solar Funnel Cooker to cook lunches over many weeks. My favourite foods to cook are potatoes (cut into logs or slices) and carrot slices. Vegetables cook slowly in their own juices and taste delicious. I also make rice, melted cheese sandwiches, and even bread in the Solar Funnel Cooker. I usually put the food out around 11:30 and let it cook until 12:45 or 1 pm, just to be sure that it has time to cook. I've never had any food burn in this cooker.

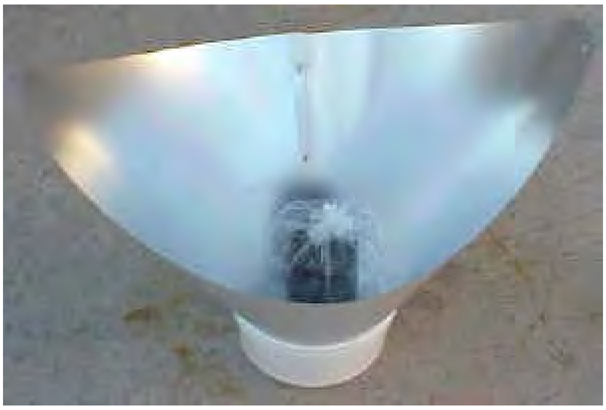
I have also cooked food in the mountains, at an altitude of around 8,300 feet. If anything, the food cooked faster there - the sunlight passes through less atmosphere at high altitudes.

I find that people are surprised that the sun alone can actually cook food. And they are further pleasantly surprised at the rich flavours in the foods which cook slowly in the sun. This inexpensive device does it!

Students at Brigham Young University have performed numerous tests on the Solar Funnel Cooker along with other cookers. We have consistently found much faster cooking using the Solar Funnel Cooker. The efficiency/cost ratio is higher than any other solar cooking device we have found to date. Mr. Hullinger also performed studies of transmissivity, reflectivity and absorptivity of alternate materials which could be used in the Solar Funnel Cooker. While there are better materials, such as solar-selective absorbers, our goal has been to keep the cost of the Solar Cooker as low as possible, while maintaining safety as a first priority.

Tests in Bolivia

The BYU Benson Institute organised tests between the Solar Funnel Cooker and the "old-fashioned" solar box oven. The solar box oven cost about $70 and was made mostly of cardboard. It took nearly two hours just to reach water pasteurisation temperature. The Bolivian report notes that "food gets cold every time the pots are taken from and into the oven." The solar box oven failed even to cook boiled eggs. (More expensive box cookers would hopefully work better.)



An aluminised-mylar Solar Funnel Cooker was also tested in Bolivia, during the Bolivian winter. Water pasteurisation temperature was reached in 50 minutes, boiled eggs cooked in 70 minutes, and rice cooked in 75 minutes. The Bolivian people were pleased by the performance. So were we! (La Paz, Bolivia, August, 1996).

I also donated two dozen solar funnel cookers for people in Guatemala. These were taken there by a group of doctors going there for humanitarian service. The people there also liked the idea of cooking with the sun's free energy. For an aluminised-Mylar Solar Funnel Cooker kit, please contact CRM (licensed manufacturer) at +1 (801) 292-9210.

Water and Milk Pasteurisation

Contaminated drinking water or milk kills thousands of people each day, especially children. The World Health Organisation reports that 80% of illnesses in the world are spread through contaminated water. Studies show that heating water to about 65º - 70º C (150º F) is sufficient to kill coliform bacteria, rotaviruses, enteroviruses and even Giardia. This is called pasteurisation.

Pasteurisation depends on how hot and how long water is heated. But how do you know if the water got hot enough? You could use a thermometer, but this would add to the cost, of course. When steam leaves the canning jar (with lid on tight) and forms "dew" on the inside of the cooking bag, then the water is probably pasteurised to drink. (The goal is to heat to 160º Fahrenheit for at least six minutes.) With a stripe of black paint scraped off the jar, one can look through the bag and into the jar and see when the water is boiling - then it is safe for sure.

Think of all the lives that can be saved simply by pasteurising water using a simple Solar Cooker!

Safety

Safety was my first concern in designing the Solar Funnel Cooker, then came low cost and effectiveness. But any time you have heat you need to take some precautions.

- The cooking vessel (jar) is going to get hot, otherwise the food inside it won't cook. Let the jar cool a bit before opening. Handle only with gloves or tongs.
- Always wear dark glasses to protect from the sun's rays. We naturally squint, but sunglasses are important.
- Keep the plastic bag away from children and away from nose and mouth to avoid any possibility of suffocation.

Cooking with the Solar Funnel Cooker

What do you cook in a crock pot or moderate-temperature oven? The same foods will cook about the same in the Solar Funnel Cooker - without burning. The charts below give approximate summer cooking times.

The solar cooker works best when the UV index is 7 or higher (Sun high overhead, few clouds).

Cooking times are approximate. Increase cooking times for partly-cloudy days, sun not overhead (e.g., wintertime) or for more than about 3 cups of food in the cooking jar.

Stirring is not necessary for most foods. Food generally will not burn in the solar cooker.

Vegetables (Potatoes, carrots, squash, beets, asparagus, etc.)
Preparation: No need to add water if fresh. Cut into slices or "logs" to ensure uniform cooking. Corn will cook fine with or without the cob.
Cooking Time: About 1.5 hours

Cereals and Grains (Rice, wheat, barley, oats, millet, etc.)
Preparation: Mix 2 parts water to every 1 part grain. Amount may vary according to individual taste. Let soak for a few hours for faster cooking. To ensure uniform cooking, shake jar after 50 minutes.
CAUTION: Jar will be hot. Use gloves or cooking pads.
Cooking Time: 1.5-2 hours

Pasta and Dehydrated Soups
Preparation: First heat water to near boiling (50-70 minutes). Then add the pasta or soup mix. Stir or shake, and cook 15 additional minutes.
Cooking Time: 65-85 minutes

Beans
Preparation: Let tough or dry beans soak overnight. Place in cooking jar with water.
Cooking Time: 2-3 hours

Eggs
Preparation: No need to add water. **Note**: If cooked too long, egg whites may darken, but taste remains the same.
Cooking Time: 1-1.5 hours, depending on desired yolk firmness.

Meats (Chicken, beef, and fish)
Preparation: No need to add water. Longer cooking makes the meat more tender.
Cooking Time: Chicken: 1.5 hours cut up or 2.5 hours whole; Beef: 1.5 hours cut up or 2.5-3 hours for larger cuts; Fish: 1-1.5 hours

Baking
Preparation: Times vary based on amount of dough.
Cooking Times: Breads: 1-1.5 hours; Biscuits: 1-1.5 hours; Cookies: 1 hour

Roasted Nuts (Peanuts, almonds, pumpkin seed, etc.)
Preparation: Place in jar. A little vegetable oil may be added if desired.
Cooking Time: About 1.5 hours

MRE's and pre-packaged foods
Preparation: For foods in dark containers, simply place the container in the cooking bag in place of the black cooking jar.
Cooking Times: Cooking time varies with the amount of food and darkness of package.

How to Use the Solar Funnel as a Refrigerator/Cooler

A university student (Jamie Winterton) and I were the first to demonstrate that the Brigham Young University Solar Funnel Cooker can be used - at night - as a refrigerator. Here is how this is done:

The Solar Funnel Cooker is set-up just as you would during sun-light hours, with two exceptions:

1. The funnel is directed at the dark night sky. It should not "see" any buildings or even trees. (The thermal radiation from walls, trees, or even clouds will diminish the cooling effect.).

2. It helps to place 2 (two) bags around the jar instead of just one, with air spaces between the bags and between the inner bag and the jar. HDPE and ordinary polyethylene bags work well, since polyethylene is nearly transparent to infrared radiation, allowing it to escape into the "heat sink" of the dark sky.

During the day, the sun's rays are reflected on to the cooking vessel which becomes hot quickly. At night, heat from the vessel is radiated *outward*, towards empty space, which is very cold indeed (a "heat sink"). As a result, the cooking vessel now becomes a small refrigerator. We routinely achieve cooling of about 20º F (10º C) below ambient air temperature using this remarkably simple scheme.

In September 1999, we placed two funnels out in the evening, with double-bagged jars inside. One jar was on a block of wood and the other was suspended in the funnel using fishing line. The temperature that evening (in Provo, Utah) was 78º F (25.5º C). Using a Radio Shack indoor/outdoor thermometer, a BYU student (Colter Paulson) measured the temperature inside the funnel and outside in the open air. He found that the temperature of the air inside the funnel dropped quickly by about 15º F (8º C), as its heat was radiated upwards in the clear sky. That night, the minimum outdoor air temperature measured was 47.5º F (8.6º C) - but the water in both jars had ICE. I invite others to try this, and please let me know if you get ice at 55 or even 60 degrees outside air temperature (minimum at night). A black PVC container may work even better than a black-painted jar, since PVC is a good infrared radiator - these matters are still being studied.

I would like to see the "Funnel Refrigerator" tried in desert climates, especially where freezing temperatures are rarely reached. It should be possible in this way to cheaply make ice for Hutus in Rwanda and for aborigines in Australia, without using any electricity or other modern "tricks." We are in effect bringing some of the cold of space to a little corner on earth. Please let me know how this works for you.

Conclusion: Why We Need Solar Cookers

The BYU Funnel Cooker/Cooler can:

- Cook food without the need for electricity or wood or petroleum or other fuels.
- Pasteurise water for safe drinking, preventing many diseases.
- Save trees and other resources.
- Avoid air pollution and breathing smoke while cooking.
- Use the sun's free energy. A renewable energy source.
- Cook food with little or no stirring, without burning.
- Kill insects in grains.
- Dehydrate fruits, etc.
- Serve as a refrigerator at night, to cool even freeze water.

(Try that without electricity or fuels!)

The burden for gathering the fuel wood and cooking falls mainly on women and children. Joseph Kiai reports :

From Dadaab, Kenya: "Women who can't afford to buy wood start at 4 am to go collecting and return about noon... They do this twice a week to get fuel for cooking... The rapes are averaging one per week."

From Belize: "Many times the women have to go into the forest dragging their small children when they go to look for wood. It is a special hardship for pregnant and nursing mothers to chop and drag trees back to the village... they are exposed to venomous snakes and clouds of mosquitoes."

And the forests are dwindling in many areas. Edwin Dobbs noted in *Audubon Magazine*, Nov. 1992, "The world can choose sunlight or further deforestation, solar cooking or widespread starvation..."

Americans should be prepared for emergencies, incident to power failures. A Mormon pioneer noted in her journal: "We were now following in their trail travelling up the Platte River. Timber was sometimes very scarce and hard to get. We managed to do our cooking with what little we could gather up..." (Eliza R. Snow) Now there's someone who needed a light-weight Solar Cooker!

Here's another reason to use a solar cooker. Many people in developing countries look to see what's being done in America. I'm told that if Americans are using something, then they will want to try it, too. The more people there are cooking with the sun, the more others will want to join in. A good way to spread this technology is to encourage small local industries or families to make these simple yet reliable solar cookers for others at low cost. I've used this cooker for three summers and I enjoy it. Cooking and making ice with the funnel cooker/cooler will permit a significant change in lifestyle. If you think about it, this could help a lot of people. The BYU Solar Funnel Cooker uses the glorious sunshine -- and the energy of the sun is a free gift from God for all to use!

Answers to commonly-asked questions

Will the cooker work in winter (in the United States)?

As the sun moves closer to the southern horizon in the winter, the solar cooker is naturally less effective. A good measure of the solar intensity is the "UV index" which is often reported with the weather. When the ultraviolet or UV index is 7 or above – common in summer months – the solar cooker works very well. In Salt Lake City in October, the UV index was reported to be 3.5 on a sunny day. We were able to boil water in the Solar Funnel Cooker during this time, but we had to suspend the black jar in the funnel so that sunlight struck all sides. (We ran a fishing line under the screw-on lid, and looped the fishing line over a rod above the funnel. As usual, a plastic bag was placed around the jar, and this was closed at the top to let the fishing line out for suspending the jar.)

The solar "minimum" for the northern hemisphere occurs on winter solstice, about December 21st each year. The solar "maximum" occurs six months later, June 21st. Solar cooking works best from about 20th March to 1st October in the north. If people try to cook with the sun for the first time outside of this time window, they should not be discouraged. Try again when the sun is more directly overhead. One may also suspend the jar in the funnel, which will make cooking faster any time of the year.

It is interesting to note that most developing countries are located near the equator where the sun is nearly directly overhead all the time. Solar Cookers will then serve year-round, as long as the sun is shining, for these fortunate people. They may be the first to apply fusion energy (of the sun) on a large scale. They may also accomplish this without the expensive infrastructure of electrical power grids that we take for granted in America.

How do you cook bread in a jar?

I have cooked bread by simply putting dough in the bottom of the jar and placing it in the funnel in the usual way. Rising and baking took place inside the jar in about an hour (during summer). One should put vegetable oil inside the jar before cooking to make removal of the bread easier. I would also suggest that using a 2-quart wide-mouth canning jar instead of a 1-quart jar would make baking a loaf of bread easier.

What is the optimum "opening angle" for the funnel cooker?

A graduate student at Brigham Young University did a calculus calculation to assess the best shape or opening angle for the Solar Funnel. Jeannette Lawler assumed that the best operation would occur when the sun's rays bounced no more than once before hitting the cooking jar, while keeping the opening angle as large as possible to admit more sunlight. (Some sunlight is lost each time the light reflects from the shiny surface. If the sunlight misses on the first bounce, it can bounce again and again until being absorbed by the black bottle). She set up an approximate equation for this situation, took the calculus derivative with respect to the opening angle and set the derivative equal to zero. Optimising in this way, she found that the optimum opening angle is about 45 degrees, when the funnel is pointed directly towards the sun.

But we don't want to have to "track the sun" by turning the funnel every few minutes. The sun moves (apparently) 360 degrees in 24 hours, or about 15 degrees per hour. So we finally chose a 60-degree opening angle so that the cooker is effective for about 1.2 hours. This turned out to be long enough to cook most vegetables, breads, boil water, etc. with the Solar Funnel Cooker. We also used a laser pointer to simulate sun rays entering the funnel at different angles, and found that the 60-degree cone was quite effective in concentrating the rays at the bottom of the funnel where the cooking jar sits.

For questions regarding the complete Solar Funnel Cooker kit using aluminised Mylar and a jar for the cooking vessel, please contact CRM at +1 (801) 292-9210.

Tests of the Solar Funnel and Bowl Cookers in 2001

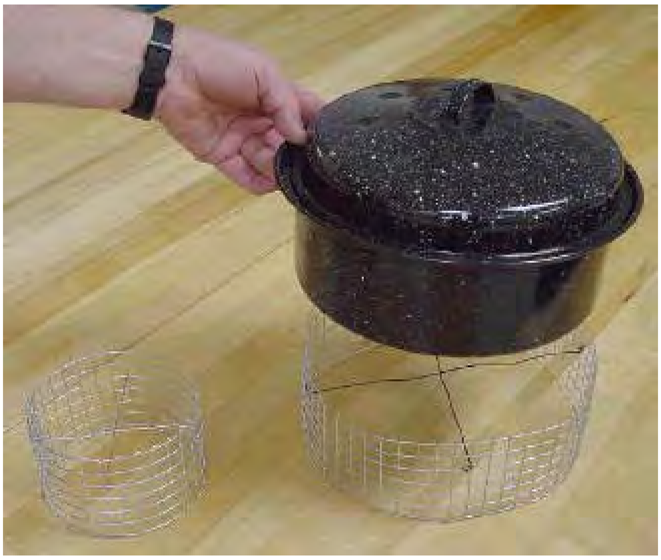
Christopher McMillan and Steven E. Jones
Brigham Young University

Introduction

With an increase in population and a decrease in available fuels such as wood and coal in developing countries, the need for alternative cooking methods has increased. Solar cookers are an alternative to conventional methods such as wood-fires and coal-fires. They provide usable heat for cooking and pasteurising water, without the harmful side effects such as smoke inhalation that non-renewable sources create. In many countries such as Haiti, Bolivia and Kenya, the need for cheap, effective, and safe cooking methods has increased due to poverty and deforestation. Solar cookers are ideal because they rely on the sun's free energy which is abundant in many of the world's poorest countries. Though there are good designs, more testing and improvement is desirable.

There are three areas of comparison that were focused on during the course of the study. The first area of comparison is in the reflective material used. The original material is a mirror-finished aluminium Mylar. Due to the mirror finish, the reflection light is very bright and can be difficult to work over when cooking. An alternative material is a matt-finish Mylar. This material diffuses the sunlight and is not as harsh on the eyes as is the mirrored finish.

The second area of concentration is on the method of containing the air that surrounds the cooker so that the cooker is kept from being cooled by convection currents. A common method is to use a clear plastic oven-safe bag around the cooking vessel. However, this method is rather tedious and awkward to use, and such bags are rarely available in developing countries. Another technique is to use a disk or window make out of a clear plastic or glass. This makes the cooker easier to use.



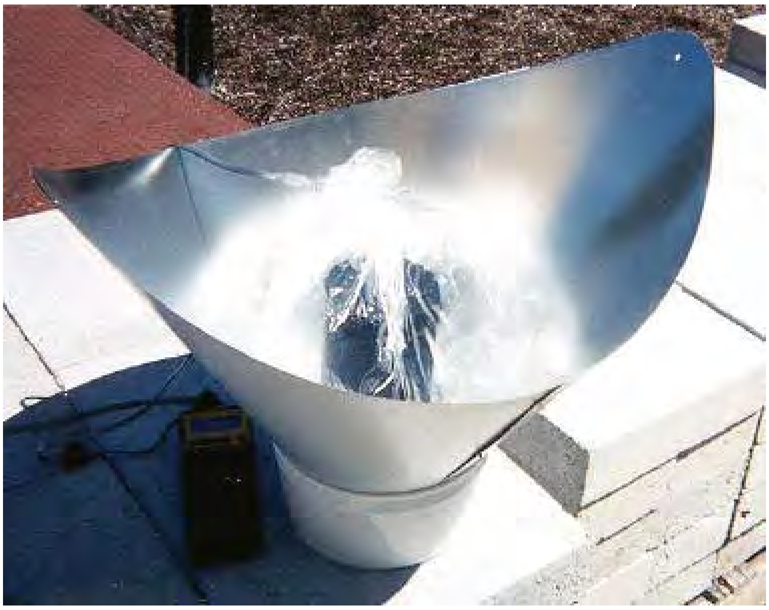
The third main area of focus is in the cooking containers used. The present cooking vessel for the Solar Funnel Cooker is a black-painted canning jar. This method is also tedious and awkward. The canning jars can be hard to clean, and they can break. Design changes are tested that would allow people to use their own cookware. This too would make the cooker more convenient to use.

The fourth area of testing pitted the wooden block support which we have been using for years against a rabbit-wire support. A rabbit-wire cylinder holds the cooking vessel up off the bottom of the cooker, and allows sunlight to strike essentially all surfaces of the cooking vessel, including the bottom.

The effectiveness of these methods is tested and compared both qualitatively and quantitatively. In addition to acquiring temperature-rise versus time data, we also cooked numerous meals in the solar cookers so as to get hands-on experience with cooking. Several students participated in these cooking tests.

Cooker Designs:

Several solar cooker designs were used during these tests. The Solar Funnel Cooker was the main cooker tested. A Solar CooKit and a bowl-shaped variation of the Solar Funnel Cooker were also tested. Most experiments were comparative tests between the various designs, and the cooker set-up was varied from test to test. The basic design of the Solar Funnel Cooker is a funnel-shaped aluminium Mylar collector. A highly reflective material is necessary to collect and concentrate the sun's rays. The funnel walls are at a 60 degree angle (with respect to the horizontal) since this collects sunlight for a two hour time period without requiring re-orientation to follow the sun. Due to the way the Mylar sheets are cut and folded, a pair of wings on opposite ends of the funnel is formed. The wings increase the collector size and create an elliptical shape at top. At the tips of the wings, the cooker stands about 20 inches high and has a diameter of about 28 inches. At the top, along the minor axis of the elliptical funnel, the cooker stands about 15 inches high, and has a diameter of about 20 inches. Since the Aluminium Mylar does not support itself well, a nine inch diameter by five inch high bucket is used to support the funnel.



The cooking container primarily tested is a glass canning jar that has been painted flat black. The black paint allows the jar to absorb the sun's rays. The canning jar works well due to the added pressure-cooker effect caused by the rubber ring on the inside of the lid. A black-enamel pot and a black-painted stainless steel canister were also used. We found immediately that raising the vessel off the bottom of the cooker using a rabbit-wire stand provided more rapid and even heating than the wooden block used previously. Placing the jar or pot on a wire stand allows as much reflected light onto the cooking vessel as possible. This allows even the bottom of the cooking container to absorb thermal energy that is reflected off the lower portion of the funnel.

Two methods of closing the cookers off from convection currents were used. It is important to keep the air that surrounds the container from circulating, thus keeping the cooking container from being cooled by convection currents or breezes. This first method used was to enclose the cooking vessel and wire stand in a clear plastic bag, such as a heat resistant Reynolds Oven Bag. It is important to make sure that the bag is not touching the cooking vessel, so once the vessel is placed into the clear bag, air is blown into the bag and the bag is tied off. This is the most common method used for solar panel cookers, such as the Solar CooKit, because of the bags' ability to withstand the temperatures attained in these types of cookers. But these bags tear rather easily and they are not readily available in developing countries and must be imported.

The second method of closing off the cooking vessel from convection currents, designed by Dr. Jones, is to place a clear plastic disk down into the funnel above the cooking vessel. The funnel used in the test was a conventional-shaped funnel that was constructed out of thin sheet metal and aluminium-foil lined for better reflectivity. The diameter of this funnel is about 30 inches at the top, and it stands about 16 inches high. The walls also form about a 60 degree angle with respect to the horizontal. This funnel was designed to hold a larger cooking container such as a pot. The diameter of the plastic disk is large enough that the disk does not touch the top of the container. For the experiments that tested this method, a one-sixteenth inch (1.6 mm) thick Lexan disk was used.

Data Collection

To collect the temperatures as a function of time, a Texas Instruments Calculator Based Laboratory (CBL) was used. This portable interface is capable of recording real-time data from multiple channels. The data were downloaded into a graphing calculator, where they can be analysed and graphed immediately. From the calculator, the data can be transferred to a computer spreadsheet such as Microsoft Excel for further analysis. Due to the nature of these experiments and the low cost to purchase the CBL, this is an ideal data collector to use. A graphing calculator was used to program the CBL and to tell it what data to collect, how many points to collect, and the time period between data points collected. Since the CBL does not have any internal programs for data collection, a program must be written into the graphing calculator. There are ready-made programs that can be uploaded into the calculator, or a custom program can be made to fit the needs of the test. The program that the CBL used allowed multiple thermocouples to collect data simultaneously. To ensure that the thermocouples were calibrated against each other, both were run on the same constant temperature sample in very close proximity. Both temperature probes agreed to within 0.21^{O}C of each other. For these experiments, this temperature difference was considered to be acceptable.

Procedure

Each experiment was conducted on the campus of Brigham Young University during mid-day, usually between 11:00 am and 2:00 pm to ensure that the sun was close to being directly over-head. This allowed as much sun light as possible to enter the solar collector. Each experiment included several steps, as listed below.

Before each experiment was set up, the volume of the water and the mass of the container were measured and recorded. The heat capacity of the water and the container were also found. The area of the cooker perpendicular to the sun's rays was also measured. To collect temperature data using thermocouple probes, small holes were drilled into the top of the canning jar and stainless steel canister lids. The jar and canister were both painted ultra-flat black to absorb as much of the sun's energy as possible.

On the morning of each test, the designated volume of water was measured out and poured into the cooking vessel. This volume ranged from 0.6 litre for one-quart jars, to 1.2 litters for half-gallon canning jars. For simultaneous testing, the same amount of water was poured into each container. The temperature probes were wired through the holes in the lids of the containers and secured about 13 mm into the water. For comparative tests, the probes were placed the same depth into the water to ensure that the probes did not read different measurements due to depth-related temperature differences within the containers. To enable later analysis; the time, ambient temperature, and solar irradiance were also noted and recorded. These numbers gave a reference point for each test. Each cooker that was to be tested was then completely set up. The temperature probes were secured through the lids, and the jar was placed into the clear oven bag – supported by a wire cage. Each bag was inflated so that no part of the bag touched the sides or top of the cooking container. The cord from the thermocouple to the CBL was passed through the top of the bag, and the bag was tied off with a twist-tie.

The test began once both cookers were completely ready and the CBL had been programmed. Care was taken to block the sun from radiating directly onto the cookers until both were ready to begin. This ensured that the water in both cookers started at very nearly the same temperature. Most tests were set up to collect one data point every four to five minutes, for up to two hours. This allowed the cooker temperatures to reach maxima and then remain at a nearly constant temperature. Once a test was complete, the cooker was disassembled and the data downloaded into the graphing calculator. Though the graphing calculator does allow analysis, a spread sheet such as Microsoft Excel is easier to use. Thus, the data from each test were downloaded from the calculator into Microsoft Excel. The elapsed time (in seconds) and the corresponding temperatures were listed next to each other. A graph of temperature versus time was made, with the Time being the horizontal axis for each test. For comparative tests, the Temperature versus Time data for both cookers was plotted on the same graph. As a reference, a trend-line was fitted to the linear portion of the graph, along with the linear regression and the coefficient of correlation (R2). It is important to have a coefficient of correlation close to one, as this is how close the linear regression fits the data. In a separate column, the temperatures were again listed, however only from 30^{O}C to 70^{O}C. The change in temperature for every ten or twelve minutes was found and logged next to the temperature column. The power output (in Watts) of each cooker could then be calculated.

To calculate the power output of the cookers for each specific test, the mass of the water and of the container were both measured. Though the thermal energy content of the container was relatively small compared to that of water (due to the large heat capacity of water), it was important to add it into the calculation. Also, since several different containers were compared, the energy content of the container was important. The power is found by:

$$Q_{(out)} = Q_{(water)} + Q_{(container)}$$

$$Q_{(out)} = (m_w c_w + m_c c_c)\Delta T$$

$$Power_{(out)} = \frac{Q_{(out)}}{\Delta t}$$

The power is found in Watts. A power output for each change in temperature for the time interval is calculated and logged next to the T column. Since there are uncertainties in all of the measurements, it is important to include the error in each power output. To do this, the error in the water's and container's measurements is taken into consideration. The error is found by:

$$\pm \Delta P = \sqrt{(\frac{\partial P}{\partial m_w}\Delta m_w)^2 + (\frac{\partial P}{\partial m_c}\Delta m_c)^2 + (\frac{\partial P}{\partial t}\Delta t)_w^2 + (\frac{\partial P}{\partial t}\Delta t)_c^2 + 2(\frac{\partial P}{\partial T}\Delta T)_w^2 + 2(\frac{\partial P}{\partial T}\Delta T)_c^2}$$

Where ±dP is the total error in the calculated error, dmw and dmc are the error in the mass of the water and container respectively, delta-Tp is the error in the temperature difference, and delta-t is the error in the time interval.

This simplifies to:

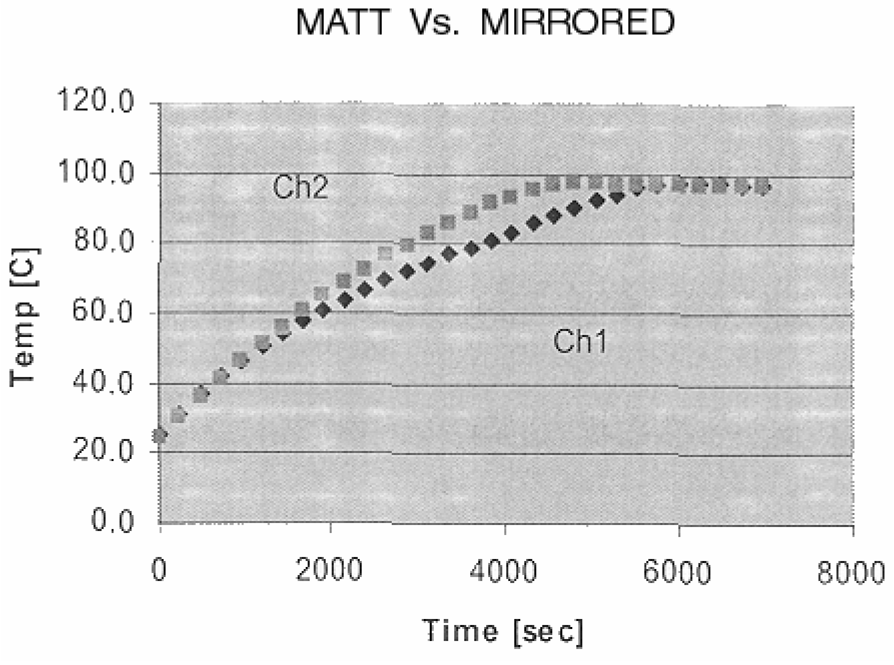
$$\pm \Delta P = \sqrt{[(\frac{c_w \Delta T}{t}\Delta m_w)^2 + (\frac{c_c \Delta T}{t}\Delta m_c)^2 + (\frac{m_w c_w \Delta T}{t^2}\Delta t)^2 + (\frac{m_c c_c \Delta T}{t^2}\Delta t)^2 + 2(\frac{m_w c_w}{t}\Delta T_p)^2 + 2(\frac{m_c c_c}{t}\Delta T_p)^2]}$$

The error was found only for the average change in temperature, rather than for each individual temperature measurement. Since the power output is dependant on the amount of energy coming in from the sun, the cooker efficiency is a good factor to calculate. To find the efficiency, the total amount of local solar radiation must be known. This should be given in watts per square metre, so that the input wattage can be found. To find the power coming in, the area of the cooker perpendicular to the sun's rays was multiplied by the solar radiation to give the amount of power that was being collected by the cooker. Since the Solar Funnel is able to be kept on track with the sun, and since the tests were done during mid-day, it was not necessary to calculate any angles. The efficiency is simply the power output divided by the power input. The solar radiation for each test was supplied by the Department of Physics and Astronomy weather station at Brigham Young University in Provo, UT, where the tests took place.

Results:

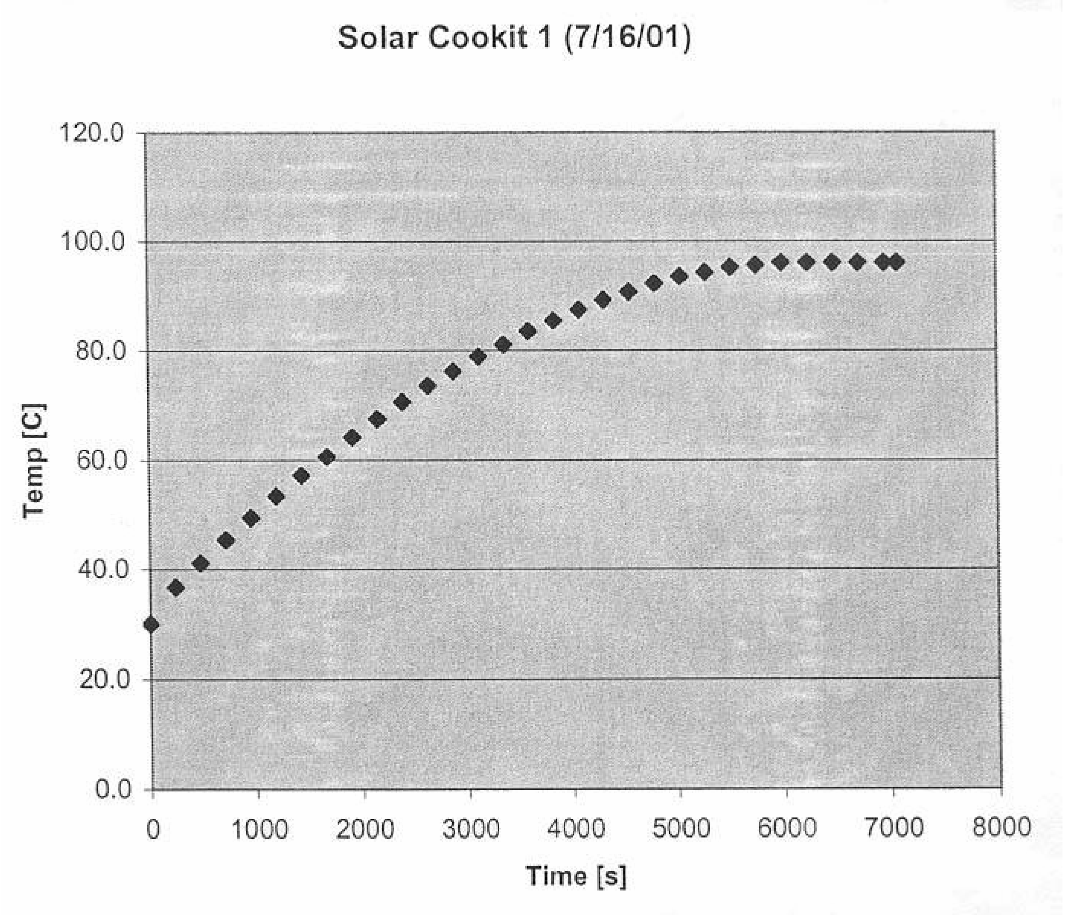
Matt vs. Mirror: Several tests were conducted on the matt versus mirror finishes. In each test, the matt finish outperformed the mirror finish. On 27 July, 2001, a matt funnel and a mirror funnel were simultaneously tested with 650 cc of water. The average power output for the mirror finish was 46.4 W ± 1.7 W, while the matt funnel put out an average of 59.4 W ± 2.1 W. The efficiency of the mirror funnel was 15.8%, while the matt was 20.2% efficient.

The following graph shows the temperatures reached by the matt and mirror funnels.



Channel 1 (Ch1) was the mirror finish, and channel 2 (Ch2) was the matt finish. This shows that both funnels peaked at about the same temperature: 97°C (207°F). The matt funnel peaked in about 76 minutes, whereas the mirror funnel peaked in 96 minutes, twenty minutes later. Though this perhaps a tolerable time difference for actual cooking, it is substantial. Every matt vs. mirror test performed in a similar way. These results are due to the way the matt funnel reflects the sun's rays. The mirror finish seems to focus a strip of light onto the cooking vessel more than the matt finish does. As a result, the matt finish diffuses the light more and the cooker is heated more uniformly. This is good, since the matt finish is easier to work with, delivering much less glare to the eyes.

The following graph shows the temperature rise with time for a Solar CooKit:



Comparing the two graphs above, we find that the Solar CoolKit performed very well, comparable to the Funnel Cooker. We should note that in both cases, we used a canning jar (pressurised) supported by a wire stand. We found that the wire stand improves the performance of the Solar CooKit significantly and hope that this support stand will be used in countries where the Solar CooKit is in use.

In tests where the use of the clear plastic disk was tested against the oven-bag, an aluminium pot was used in the disk-set-up. In these tests, the cooker with an oven bag outperformed the cooker using a plastic disk. On 10 August, 2001, a test was run which compared the disk/pot set-up against the oven-bag/jar set-up. Both cookers follow similar heating paths with time, but the oven-bag/jar did slightly better. Due to the higher mass of the jar compared to the mass of the aluminium pot, and the much higher heat capacity of the water, the average power output for the oven-bag/jar was 39.8 ± 1.4 W, while the disk/pot put out 30.3 W ± 1.2 W. The efficiency of the oven-bag/jar was 14.7% and the efficiency of the disk/pot set-up was 10.4% for this test. This is also partly due to the pressure-cooker effect that the canning jar produces. Though this is a considerable efficiency difference, the disk/pot set-up did very well in subjective tests where food was actually cooked and tasted. In all cases where the disk/pot set-up was used to cook food, the food cooked in about the same amount of time. The ease of the disk/pot set-up is also an important consideration. Overall, in tests where food was cooked, the disk/pot set-up was preferred over the oven-bag/jar set-up.

Conclusions:

As many countries are depleting their natural resources due to increased population and the resulting deforestation, methods other than burning wood are needed to cook food and pasteurise water. Solar cookers provide a sustainable technology that relies on the sun's free energy. We report several advances to make them better. The need for cheap and effective solar cookers is very great and growing.

The Solar Funnel Cooker has been designed to meet the growing need by being inexpensive and effective. We determined that the Solar CooKit was nearly as effective when a rabbit-wire stand was used to support the cooking vessel. By collecting time vs. temperature data, quantitative analysis has been done. This analysis approach is useful for further development of the cookers.

Several areas of research were explored in 2001. Two finishes were tested for the reflector, a matt finish and a mirror finish. The benefits of the matt over the mirror finish are:

1) The matt finish is easier to work over because the sun's glaring reflection is diffused, and
2) the matt finish out-performs the mirror finish in temperature vs. time tests.

The method of closing off the cooker from convection current was tested and compared with an alternative method – a clear plastic disk. The use of a pot rather that a canning jar was also tested. Though the present oven-bag/jar method does outperform the disk/pot method, the disk/pot method is easier to use and seems to be nearly as efficient. Finally, we showed that a wire-mesh stand is a considerable improvement over the use of a wooden block or other opaque stand for the cooking vessel. We join with our fellow researchers around the world in pursuing further development of solar cookers, particularly to benefit people in developing countries.

Recent Advances in Solar Water Pasteurisation

Boiling isn't necessary to kill disease microbes

The main purpose of solar cookers is to change sunlight into heat which is then used to cook foods. We are all familiar with how successful solar cookers are at cooking and baking a wide variety of foods. In this article I want to consider using the heat in solar cookers for purposes other than cooking. My main focus will be solar water pasteurisation, which can complement solar cooking and address critical health problems in many developing countries.

The majority of diseases in developing countries today are infectious diseases caused by bacteria, viruses, and other microbes which are shed in human faeces and polluted water which people use for drinking or washing. When people drink the live microbes, they can multiply, cause disease, and be shed in faeces into water, continuing the cycle of disease transmission.

World-wide, unsafe water is a major problem. An estimated one billion people do not have access to safe water. It is estimated that diarrhoeal diseases that result from contaminated water kill about 2 million children and cause about 900 million episodes of illness each year.

Boiling contaminated water

How can infectious microbes in water be killed to make the water safe to drink? In the cities of developed countries this is often guaranteed by chlorination of water after it has been filtered. In developing countries, however, city water systems are less reliable, and water from streams, rivers and some wells may be contaminated with human faeces and pose a health threat. For the billion people who do not have safe water to drink, what recommendation do public health officials offer? The only major recommendation is to boil the water, sometimes for up to 10 minutes. It has been known since the time of Louis Pasteur 130 years ago that heat of boiling is very effective at killing all microbes which cause disease in milk and water.

If contaminated water could be made safe for drinking by boiling, why is boiling not uniformly practised? There seem to be five major reasons:

1) people do not believe in the germ theory of disease,
2) it takes too long,
3) boiled water tastes bad,
4) fuel is often limited or costly,
5) the heat and smoke are unpleasant.

Some examples of the cost of boiling water are worth mentioning. During the cholera outbreak in Peru, the Ministry of Health urged all residents to boil drinking water for 10 minutes. The cost of doing this would amount to 29% of the average poor household income. In Bangladesh, boiling drinking water would take 11% of the income of a family in the lowest quartile. In Jakarta, Indonesia, more than $50 million is spent each year by households for boiling water. It is estimated that in the city of Cebu in the Philippines, population about 900,000, about half the families boil their drinking water, and the proportion is actually higher for families that obtain their water from an unreliable chlorinated piped supply. Because the quantities of fuel consumed for boiling water are so large, approximately 1 kilogram of wood to boil 1 litre of water, and because firewood, coal, and coke are often used for this purpose, an inadequate water supply system significantly contributes to deforestation, urban air pollution, and other energy-related environmental effects.

If wood, charcoal, or dung is used as fuel for boiling water, the smoke creates a health hazard, as it does all the time with cooking. It is estimated that 400 to 700 million people, mainly women, suffer health problems from this indoor air pollution. As a microbiologist, I have always been perplexed as to why boiling is recommended, when this is heat far in excess of that which is necessary to kill infectious microbes in water. I presume the reason boiling is recommended is to make sure that lethal temperatures have been reached, since unless one has a thermometer it is difficult to tell what temperature heated water has reached until a roaring boil is reached. Everyone is familiar with the process of milk pasteurisation. This is a heating process which is sufficient to kill the most heat resistant disease causing microbes in milk, such as the bacteria which cause tuberculosis, undulant fever, streptococcal infections and Salmonellosis. What temperatures are used to pasteurise milk? Most milk is pasteurised at 71.7^{O} C (161^{O} F) for only 15 seconds. Alternatively, 30 minutes at 62.8^{O} C (145^{O} F) can also pasteurise milk. Some bacteria are heat resistant and can survive pasteurisation, but these bacteria do not cause disease in people. They can, however, spoil the milk, so pasteurised milk is kept refrigerated.

There are some different disease microbes found in water, but they are not unusually heat resistant. The most common causes of water diseases, and their heat sensitivity, are presented in Table 1. The most common causes of acute diarrhoea among children in developing countries are the bacteria Escherichia coli and Shigelia SD. and the Rotavirus group of viruses. These are rapidly killed at temperatures of 60^{O} C or greater.

Solar water pasteurisation

As water heats in a solar cooker, temperatures of 56^{O} C and above start killing disease-causing microbes. A graduate student of mine, David Ciochetti, investigated this for his master's thesis in 1983, and concluded that heating water to 66^{O} C in a solar cooker will provide enough heat to pasteurise the water and kill all disease causing microbes. The fact that water can be made safe to drink by heating it to this lower temperature - only 66^{O} C - instead of 100^{O} C (boiling) presents a real opportunity for addressing contaminated water in developing countries.

Testing water for faecal contamination

How can one readily determine if the water from a well, pump, stream, etc. is safe to drink? The common procedure is to test the water for bacterial indicators of faecal pollution. There are two groups of indicators which are used. The first is the coliform bacteria which are used as indicators in developed countries where water is chlorinated. Coliform bacteria may come from faeces or from plants. Among the coliform bacteria is the second indicator, Escherichia coli. This bacterium is present in large numbers in human faeces (approximately 100,000,000 per gram of faeces) and that of other mammals. This is the main indicator used if water is not chlorinated. A water source containing 100 E. coli per 100 ccs poses a substantial risk of disease.

The standard method of testing water for the presence of coliforms and E. coli requires trained personnel and a good laboratory facility or field unit which are usually not present in developing countries. Thus, water supplies are almost never tested.

A new approach to testing in developing countries

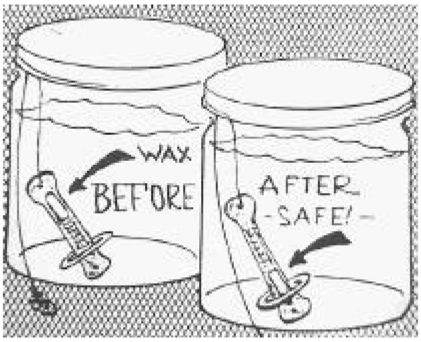
In 1987, the Colilert MPM Test (CLT) was introduced as the first method which used a defined substrate technology to simultaneously detect coliforms and E. coli. The CLT comes as dry chemicals in test tubes containing two indicator nutrients: one for coliforms and one for E. coli. The CLT involves adding 10 ml of water to a tube, shaking to dissolve the chemicals, and incubating at body temperature for 24 hours. I prefer incubating tubes under my belt against my body. At night I sleep on my back and use night clothes to hold the tubes against my body.

If no coliform bacteria are present, the water will remain clear. However, if one or more coliforms are present in the water, after 24 hours their growth will metabolise ONPG and the water will change in colour from clear to yellow (resembling urine). If E. coli is among the coliform bacteria present, it will metabolise MUG and the tube will fluoresce blue when a battery-operated, long-wave ultraviolet light shines on it, indicating a serious health hazard. I have invited participants at solar box cooker workshops in Sierra Leone, Mali, Mauritania, and Nepal to test their home water supplies with CLT. One hundred and twenty participants brought in samples. In all four countries, whether the water was from urban or rural areas, the majority of samples contained coliforms, and at least half of these had E. coli present. Bacteriological testing of the ONPG and MUG positive tubes brought back from Mali and Mauritania verified the presence of coliforms/E. coli in approximately 95% of the samples. It is likely that soon the Colilert MPN test will be modified so that the test for E. coli will not require an ultraviolet light, and the tube will turn a different colour than yellow if E coli is present. This will make the test less expensive and easier to widely use in developing countries to assess water sources.

Effect of safe water on diarrhoea in children

What would be the effect if contaminated water could be made safe for drinking by pasteurisation or boiling? One estimate predicts that if in the Philippines, families at present using moderately contaminated wells (100 E. coli per 100 ml) were able to use a high-quality water source, diarrhoea among their children would be reduced by over 30%. Thus, if water which caused a MUG (+) test were solar pasteurised so it would be clear, this would help reduce the chance of diarrhoea, especially in children.

Water pasteurisation indicator



How can one determine if heated water has reached 65^{O} C? In 1988, Dr. Fred Barrett (USDA, retired) developed the prototype for the Water Pasteurisation Indicator (WAPI). In 1992, Dale Andreatta, a graduate engineering student at the University of California, Berkeley, developed the current WAPI. The WAPI is a polycarbonate tube, sealed at both ends, partially filled with a soybean fat which melts at 69^{O} C

("MYVEROL" 18-06K, Eastman Kodak Co., Kingsport, TN 37662). The WAPI is placed inside a water container with the fat at the top of the tube. A washer will keep the WAPI on the bottom of the container, which heats the slowest in a solar box cooker. If heat from the water melts the fat, the fat will move to the bottom of the WAPI, indicating water has been pasteurised. If the fat is still at the top of the tube, the water has not been pasteurised.

The WAPI is reusable. After the fat cools and becomes solid on the bottom, the fish line string is pulled to the other end and the washer slides to the bottom, which places the fat at the top of the tube. Another pasteurisation indicator has been developed by Roland Saye which is based on expansion of a bi-metal disc which is housed in a plastic container. This also shows promise and is in the early testing stages. The WAPI could be useful immediately for people who currently boil water to make it safe to drink. The WAPI will indicate clearly when a safe temperature has been reached, and will save much fuel which is currently is being wasted by excessive heating.

[Editor's note: Using Beeswax & Carnauba Wax to Indicate Temperature: In SBJ #15 we discussed using beeswax, which melts at a relatively low 62^{O} C, as an indicator of pasteurisation. We have now found that mixing a small amount of carnauba was with the beeswax (~1:5 ratio) raises the melting temperature of the beeswax to 70^{O} - 75^{O} C. Carnauba wax is a product of Brazil and can be bought in the US at woodworking supply stores. Further testing needs to be done to confirm that the melting point remains the same after repeated re-melting.

Different strategies for solar water pasteurisation

The solar box cooker was first used to pasteurise water. David Ciochetti built a deep-dish solar box cooker to hold several gallons of water. At this time of the year in Sacramento, three gallons could be pasteurised on our typical sunny days.

Dale Andreatta and Derek Yegian of the University of California. Berkeley, have developed creative ways to greatly increase the quantity of water which can be pasteurised, as we will hear about at this conference.

I am also excited about the possibility of pasteurising water using the simple solar panel cookers. By enclosing a dark water container in a polyester bag to create an insulating air space, and by using lots of reflectors to bounce light onto the jar, it is possible to pasteurise useful amounts of water with a simple system. It takes about four hours for me to pasteurise a gallon of water in the summer with the system I am using. Solar panel cookers open up enormous possibilities for heating water not only for pasteurisation, but also for making coffee and tea, which are quite popular in some developing countries. The heated water can also be kept hot for a long time by placing it in its bag inside an insulated box. In the insulated container I use, a gallon of 80^{O} C water will be approximately 55^{O} C after 14 hours. Water at a temperature of 55^{O} C will be about 40^{O} C after 14 hours, ideal for washing/shaving in the morning.

I will close with some advice from the most famous microbiologist, who pioneered the use of vaccinations in the 1890s: Louis Pasteur. When he was asked the secret of his success, he responded that above all else, it was persistence. I will add that you need good data to be persistent about, and we certainly have that with solar cookers; the work in Sacramento, Bolivia, Nepal, Mali, Guatemala, and wherever else the sun shines. Continued overuse of fuel-wood is non-sustainable. We need to persist until the knowledge we have spreads and becomes common knowledge world-wide.

Editor's Note: Testing Water in Developing Countries

The Colilert system makes it possible to test water without the need for a laboratory. IDEXX Laboratories, the manufacturer, recommends that you use five test tubes for each sample. Bob Metcalf explains that five tubes would comprise 50 ml, which is the minimum sample size permitted by US law. This is an unrealistically high standard by which to judge the water in developing countries where you are examining water that is already being drunk, in spite of the fact that it may be making people sick. By using a single test tube (10 ml) there is a very small chance that your sample missed the small number of bacteria that might have been present.

IDEXX Laboratories will also tell you that you need an incubator to achieve valid results. Again, Bob Metcalf tells us that all that is needed is to keep the tubes close to your body for 36 hours, since body temperature is the correct incubation temperature.

What you are actually measuring in the test is the presence of 1) coliform bacteria, and 2) E. coli, a type of coliform bacteria that is largely found in faecal matter. A positive test for coliform bacteria might be due to coliform bacteria that has washed off of plant leaves , and thus be fairly innocuous. A positive test for E. coli, however, would indicate that any bacteriological contamination was from a faecal source, which might also contain Giardia, cholera, or other serious infectious microbes.

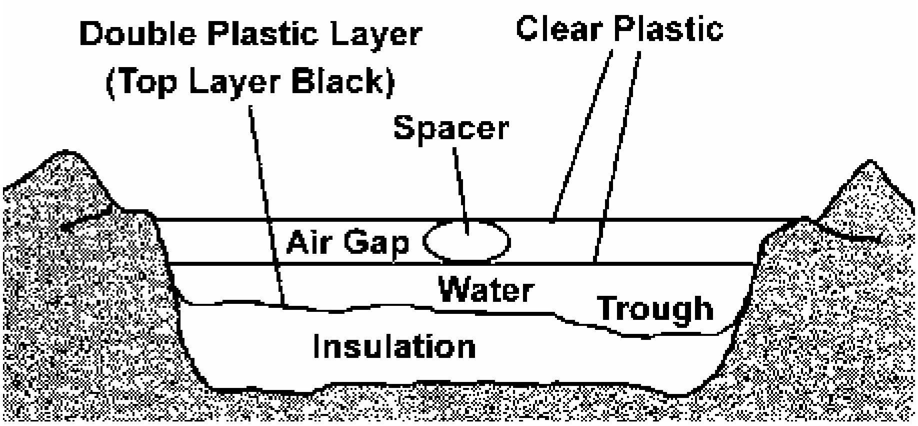
The Solar Puddle

A new water pasteurisation technique for large amounts of water

The lack of clean drinking water is a major health problem in the developing world. To reduce this health risk ways of producing clean water at an affordable cost are needed, and people need to be educated about germs and sanitation, lest they accidentally re-contaminate their clean drinking water. Recently, several of us at the University of California at Berkeley have attacked the first of these requirements. Previous issues of this newsletter have included stories about our water pasteurisation indicator and our flow-through water pasteurises based on a design by PAX World Service. In this article we describe a new low-cost device that pasteurises water.

For those not familiar with the pasteurisation process, if water is heated to 149^{O} F (65^{O} C) for about 6 minutes all the germs, viruses, and parasites that cause disease in humans are killed, including cholera and hepatitis A and B. [Ed. We have reports from the field that at 145^{O} F (63^{O} C) in a solar puddle, bacterial growth might actually be increased. Since this temperature is very close to the minimum pasteurisation temperature mentioned in this article, we suggest that you heat the water to a higher temperature and perform tests before adopting a solar puddle as your method of pasteurisation]. This is similar to what is done with milk and other beverages. It is not necessary to boil the water as many people believe. Pasteurisation is not the only way to decontaminate drinking water, but pasteurisation is particularly easy to scale down so the initial cost is low.

The new device is called a solar puddle, and it is essentially a puddle in a greenhouse. One form of the solar puddle is sketched in the figure below, though many variations are possible.



One begins by digging a shallow pit about 4 inches deep. The test device was a "family-size" unit, about 3.5 feet by 3.5 feet, but the puddle could be made larger or smaller. If the puddle is made larger there is more water to pasteurise, but there is also proportionately more sunshine collected. The pit is filled with 2 to 4 inches of solid insulation. We used wadded paper, but straw, grass, leaves, or twigs could be used. This layer of insulation should be made flat, except for a low spot in one corner of the puddle.

Put a layer of clear plastic and then a layer of black plastic over the insulation with the edges of the plastic extending up and out of the pit. Two layers are used in case one develops a small leak. We used inexpensive polyethylene from a hardware store, though special UV stabilised plastic would last longer. Put in some water and flatten out the insulation so that the water depth is even to within about 0.5 inch throughout the puddle, except in the trough which should be about 1 inch deeper than the rest. Put in more water so that the average depth is 1 to 3 inches depending on how much sunshine is expected.

A pasteurisation indicator (available from Solar Cookers International at 916/455-4499) should go in this trough since this is where the coolest water will collect. Put a layer of clear plastic over the water, again with the edges extending beyond the edges extending beyond the edges of the pit. Form an insulating air gap by putting one or more spacers on top of the third layer of plastic (large wads of paper will do) and putting down a fourth layer of plastic, which must also be clear. The thickness of the air gap should be 2 inches or more. Pile dirt or rocks on the edges of the plastic sheets to hold them down. The puddle is drained by siphoning the water out, placing the siphon in the trough and holding it down by a rock or weight. If the bottom of the puddle is flat, well over 90% of the water can be siphoned out.

Once the puddle is built it would be used by adding water each day, either by folding back the top two layers of plastic in one corner and adding water by bucket, or by using a fill siphon. The fill siphon should NOT be the same siphon that is used to drain the puddle, as the fill siphon is re-contaminated each day, while the drain siphon MUST REMAIN CLEAN. Once in place the drain siphon should be left in place for the life of the puddle.

The only expensive materials used to make the puddle are a pasteurisation indicator (about $2 for the size tested). All of these items are easily transportable, so the solar puddle might be an excellent option for a refugee camp if the expertise were available for setting them up.

Many tests were done in the spring and summer of this year in Berkeley, California. On days with good sunshine the required temperature was achieved even with 17 gallons of water (2 1/2 inch depth). About 1 gallon is the minimum daily requirement per person, for drinking, brushing one's teeth, and dish washing. With thinner water layers higher temperatures can be reached. With 6 gallons (1 inch depth) 176^{O} F was achieved on one day.

The device seems to work even under conditions that are not ideal. Condensation in the top layer of plastic doesn't seem to be a problem, though if one gets a lot of condensation the top layer should be pulled back to let the condensation evaporate. Small holes in the top layers don't make much difference. The device works in wind, or if the bottom insulation is damp. Water temperature is uniform throughout the puddle to within 2^{O} F.

After some months the top plastic layers weaken under the combined effects of sun and heat and have to be replaced, but this can be minimised by avoiding hot spots. Another option would be to use a grade of plastic that is more resistant to sunlight. The two bottom layers of plastic tend to form tiny tears unless one is very careful in handling them, (that is why there are two layers on the bottom). A tiny hole may let a little water through and dampen the solid insulation, but this is not a big problem.

There are many variations of the solar puddle. We've been able to put the top layer of plastic into a tent-like arrangement that sheds rain. This would be good in a place that gets frequent brief showers. Adding a second insulating layer of air makes the device work even better, though this adds the cost of an extra layer of plastic. As mentioned the device can cover a larger or smaller area if more or less water is desired. One could make a water heater by roughly tripling the amount of water so that the maximum temperature was only 120° F or so, and this water would stay warm well into the evening hours. This water wouldn't be pasteurised though. One could help solve the problem of dirty water vessels by putting drinking cups into the solar puddle and pasteurising them along with the water. The solar puddle could possibly cook foods like rice on an emergency basis, perhaps in a refugee camp.

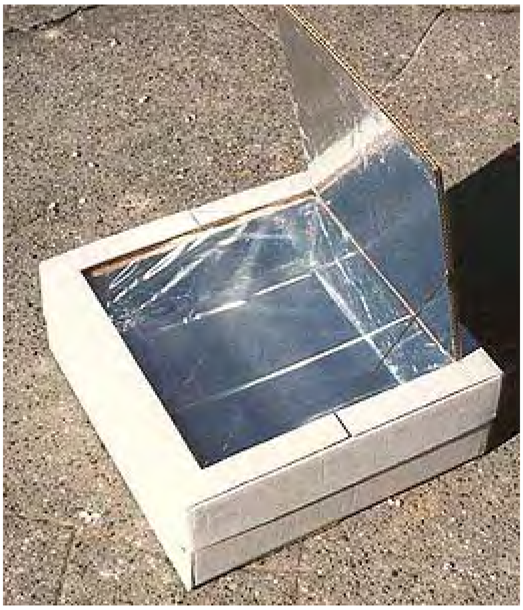
The “Easy Lid” Solar Cooker.

Designed by Chao Tan and Tom Sponheim



Although designs for cardboard cookers have become more simple, fitting a lid can still be difficult and time consuming. In this version, a lid is formed automatically from the outer box.

Making the Base

Take a large box and cut it in half as shown in Figure 1. Set one half aside to be used for the lid. The other half becomes the base.

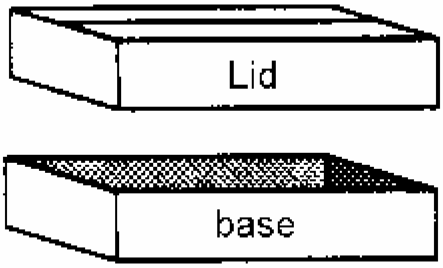


Figure 1

Fold an extra cardboard piece so that it forms a liner around the inside of the base (see Figure 2).

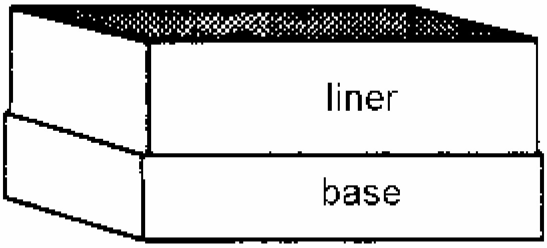

Figure 2

Use the lid piece as shown in Figure 3 to mark a line around the liner.

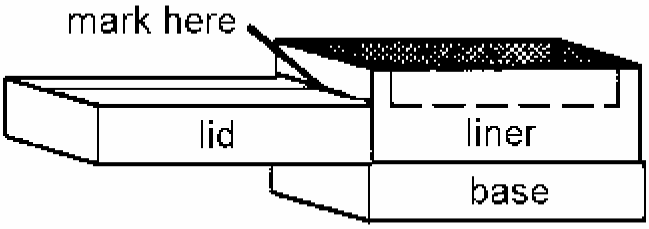

Figure 3

Cut along this line, leaving the four tabs as shown in Figure 4.

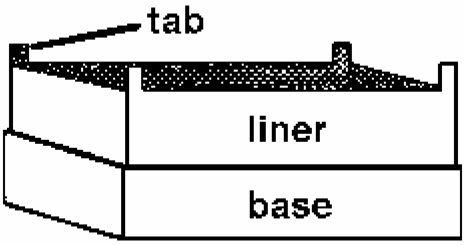

Figure 4

Glue aluminium foil to the inside of the liner and to the bottom of the outer box inside.

Set a smaller (inner) box into the opening formed by the liner until the flaps of the smaller box are horizontal and flush with the top of the liner (see Figure 5). Place some wads of newspaper between the two boxes for support.

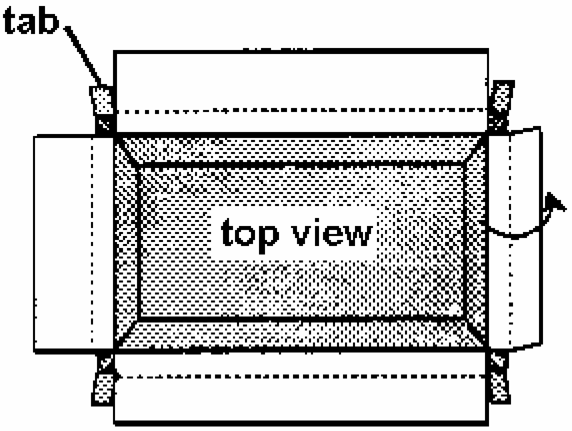

Figure 5

Mark the underside of the flaps of the smaller box using the liner as a guide.

Fold these flaps down to fit down around the top of the liner and tuck them into the space between the base and the liner (see Figure 6).

Fold the tabs over and tuck them under the flaps of the inner box so that they obstruct the holes in the four corners (see Figure 6).

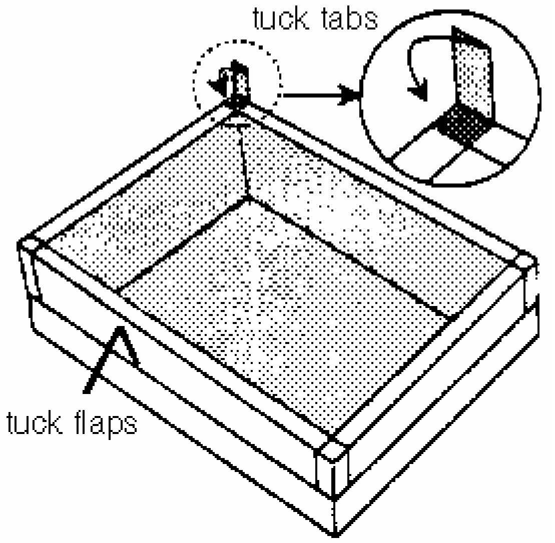

Figure 6

Now glue these pieces together in their present configuration.

As the glue is drying, line the inside of the inner box with aluminium foil.

Finishing the Lid

Measure the width of the walls of the base and use these measurements to calculate where to make the cuts that form the reflector in Figure 7. Only cut on three sides. The reflector is folded up using the fourth side as a hinge.

Glue plastic or glass in place on the underside of the lid. If you are using glass, sandwich the glass using extra strips of cardboard. Allow to dry.

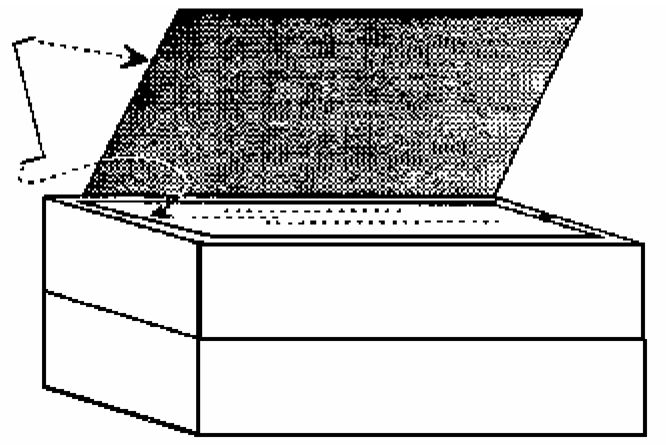

Figure 7

Bend the ends of the wire as shown in Figure 7 and insert these into the corrugations on the lid and on the reflector to prop open the latter.

Paint the sheet metal (or cardboard) piece black and place it into the inside of the oven.

Improving Efficiency

Glue thin strips of cardboard underneath the sheet metal (or cardboard) piece to elevate it off of the bottom of the oven slightly.

Cut off the reflector and replace it with one that is as large as (or larger than) the entire lid. This reflects light into the oven more reliably.

Turn the oven over and open the bottom flaps. Place one foiled cardboard panel into each airspace to divide each into two spaces. The foiled side should face the centre of the oven.

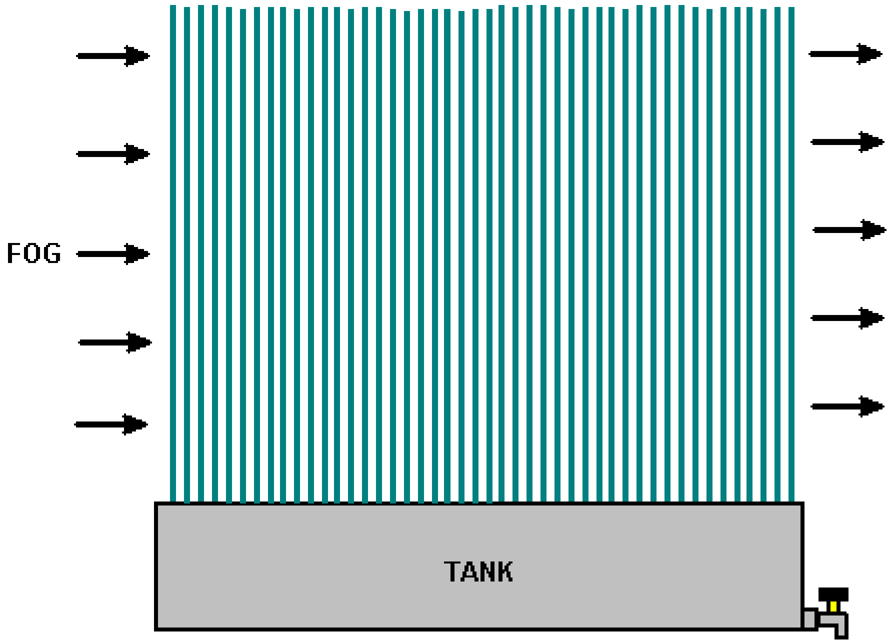
Drinking Water Collection Systems.

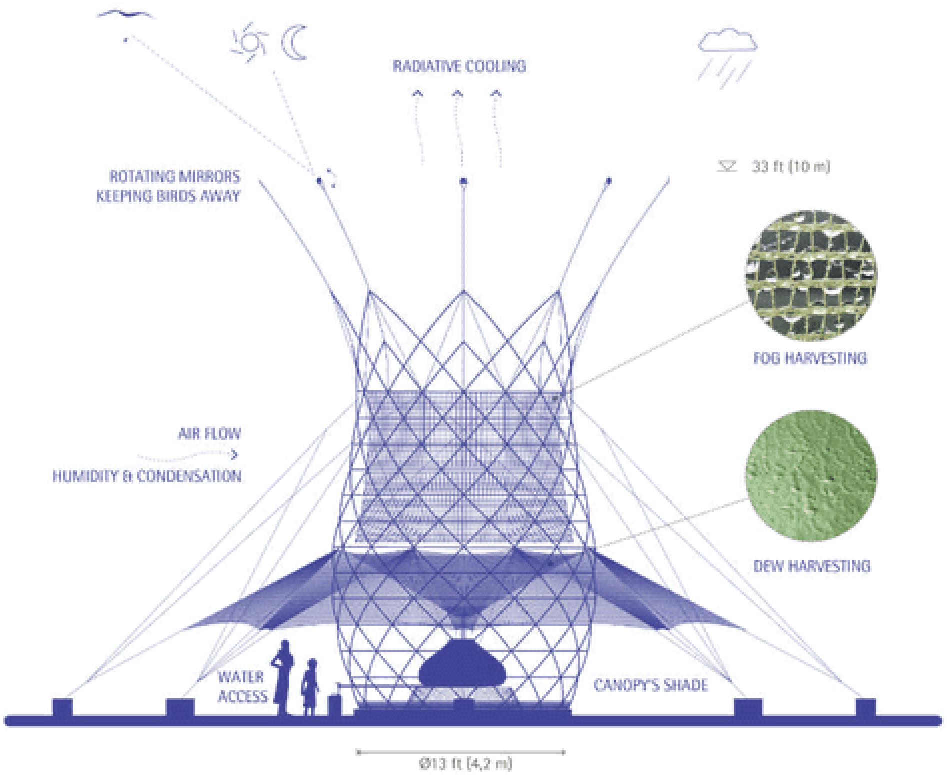
Getting adequate drinking water can often be a problem as there are many places where the local water supply is heavily contaminated with poisons, deadly organisms or both. While it is definitely much better to drink purified water than seriously contaminated water, it should be understood that most of the systems mentioned here, produce either distilled water or something very close to distilled water. Drinking distilled water for more than a few weeks is not ideal as distilled water is able to dissolve almost anything and it can do that perfectly well inside your body, removing essential minerals and other important items. So, if possible, avoid drinking distilled water for lengthy periods of time unless there is no other option other than seriously contaminated water carrying diseases and poisons.

One solution introduced for an area where there is almost never any rainfall is particularly interesting. This region gets fogs in the early morning, so plastic devices were constructed to take advantage of this fact. The devices were like plastic clothes brushes with long, slender vertical projections. The fog encountering these, condenses into freshwater droplets on the surface of these vertical fronds and run down the fronds into a plastic tank which forms the base of the device. No moving parts. No input power needed, but the result is large quantities of drinking water every morning. There is very little evaporation from the tanks, due to the small surface area of the stored water:



This effect is very noticeable on foggy days where trees drip water extensively due the fog depositing moisture on the leaves and branches.

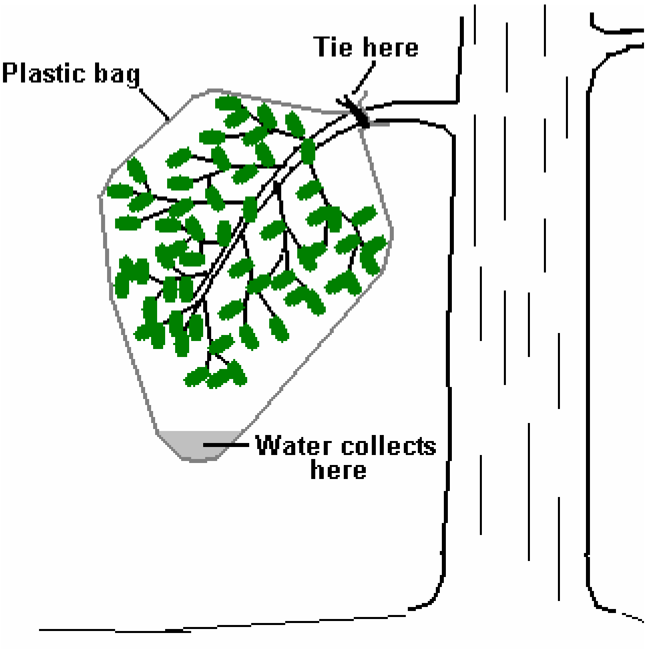
At http://www.wired.com/2015/01/architecture-and-vision-warkawater/ there is shown a very large (and comparatively expensive at £1000 each) and very elegantly designed version of this, designed in Italy and called the “warkawater” tower:



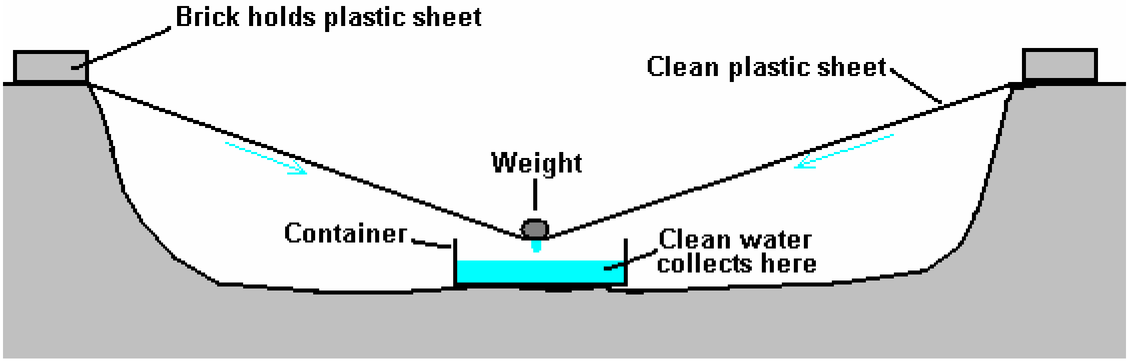
RADIATIVE COOLING
ROTATING MIRRORS
KEEPING BIRDS AWAY
33 ft (10 m)
FOG HARVESTING
AIR FLOW
HUMIDITY & CONDENSATION
DEW HARVESTING
WATER
ACCESS
CANOPY'S SHADE
Ø13 ft (4,2 m)

Supplied in kit form, using structural members made of bamboo, this unit is 4 metres wide and 9 metres tall with rotating mirrors to scare birds away. With passive water collection from fog, rain and dew, tested in Ethiopia it can produce between 50 and 100 litres per day. The condensation material is plastic netting.

An emergency measure where water is needed, is to fasten a clean plastic bag around a branch of a tree. Trees lift a large amount of water through their root systems and a good deal of that water exist from the leaves of the tree. The plastic bag intercepts that moisture loss and collects it as clean water:



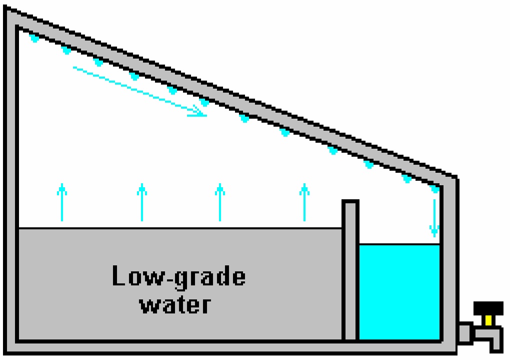
Another emergency measure is to use a clean plastic sheet and a hole dug in the ground. A clean container is placed in the centre of the hole and the plastic sheet used to cover the hold. The sheet is held around the edges of the hole with stones or any other suitable heavy material – bricks, timber, etc. A weight is then placed in the centre of the plastic sheet, pulling it down into a slope in every direction and forming an inverted peak over the container:



The area under the plastic sheet is heated by the greenhouse effect. Moisture also comes from the earth inside the enclosed hole. The moisture in the air in the cavity condenses on the underside of the plastic sheet. But as the plastic sheet is shaped into an inverted pyramid due to the weight just above the container, the water runs down and drips into the container. Again, no input power required and no moving parts.

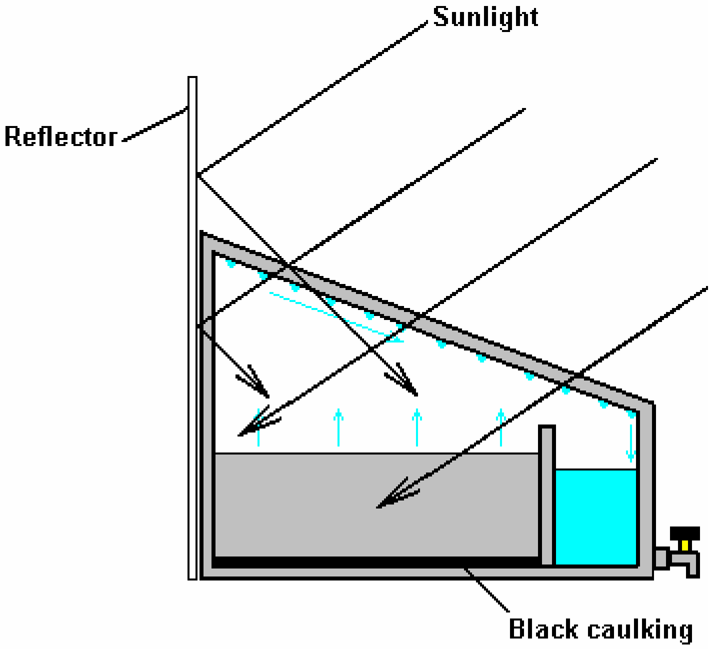
While these methods produce good quality water which is effectively distilled water, it should not be considered to be sterile and immediately ready for human consumption, even though any risk from drinking it 'as-is' is likely to be very low. There will always be air-borne pathogens, and the 'clean' components used to collect the water in the first place may not be as clean as was thought. The same applies to the excellent quality water produced by dehumidifiers, where the inner working surfaces cannot be considered sterile after the equipment has been used for any length of time. To raise the water quality, boiling briefly, microwaving the water or it to UV radiation should kill any remaining harmful organisms in the water and make it fit for consumption.

By applying these same methods on a more permanent basis, leads to the construction of devices of the type that can produce clean water at the rate of 4 litres for every 8 square feet (0.75 square meters) of glass area in only 5 hours of sunshine:

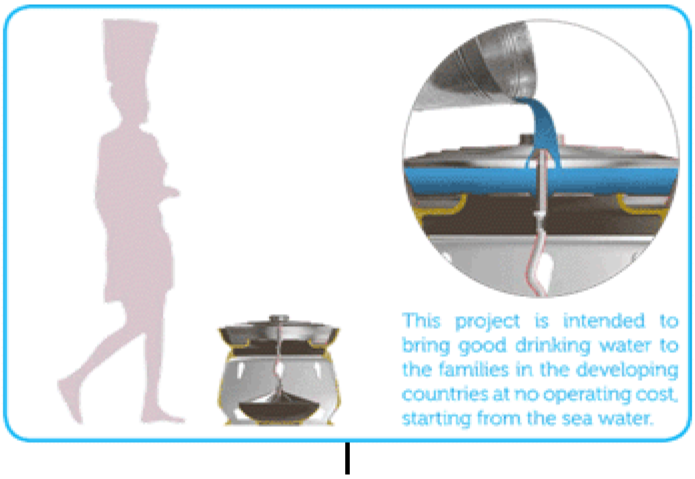


There can be many variations on this shape. These devices are generally built either with glass lids or the whole construction in acrylic sheet. Here, the greenhouse effect heats the inside of the box, causing evaporation of the water inside. This condenses on the walls and lid of the box, where it runs down and into the clean-water section. Please remember that after a long period of use, the device needs to be cleaned very carefully and to deal with air-borne bacteria, the water could be treated briefly with UV light.

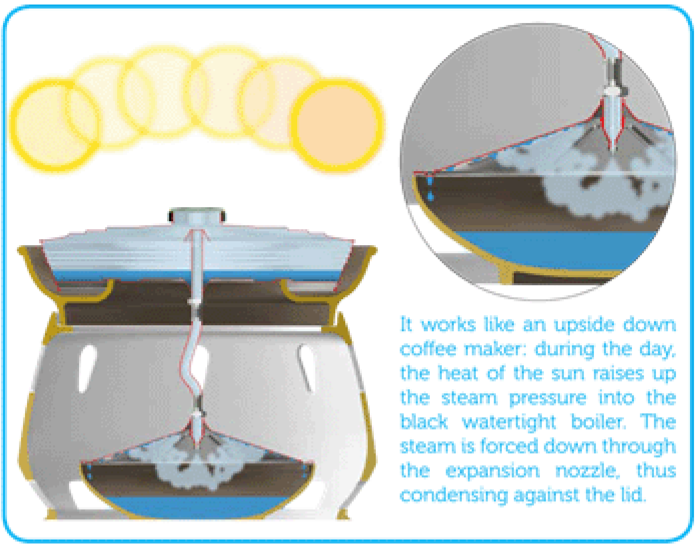
This particular design can be further enhanced as shown on the http://www.permapak.net/solarstill.htm web site, where the heating inside the box is upgraded by using black high-temperature silicone to coat the inside of the bottom of the case. The black material absorbs sunlight particularly well and so helps to heat the water. Another enhancement is to place a reflector, possibly made from aluminium foil, behind the unit in order to increase the amount of sunlight or UV radiation reaching the water inside the box:



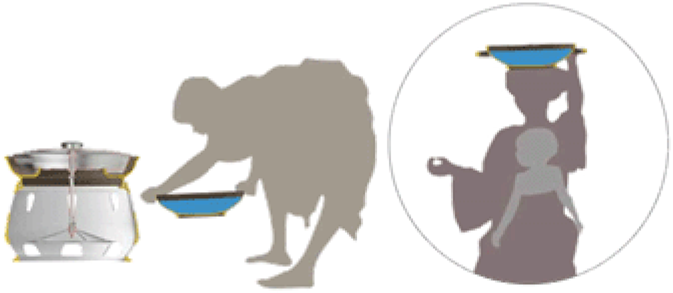
The web site http://www.gabrielediamanti.com/projects/eliodomestico---how-does-it-work/ shows details of what is considered to be a very effective, low-cost unit aimed at undeveloped countries. Please visit that site where there is a ‘Donations’ button which allows you to support this excellent work. The designer Gabriele Diamanti says “Eliodomestico is an open project, free to the people who need it. I would really appreciate if you would like to help me in the development of this project!”. It works like this:



This project is intended to bring good drinking water to the families in the developing countries at no operating cost, starting from the sea water.



It works like an upside down coffee maker: during the day, the heat of the sun raises up the steam pressure into the black watertight boiler. The steam is forced down through the expansion nozzle, thus condensing against the lid.



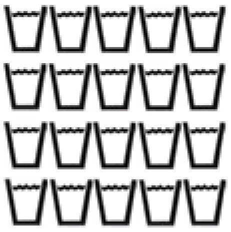
At the end of the day the **Eliodomestico** delivers 5 liters of fresh drinking water. The lower basin is specifically designed for the transport over the head, supporting this common habit.

Eliodomestico is entirely made from poor, widely available materials. The tecnologies involved in the production are very simple and popular. This also make the maintenance much easier.

- No electricity
- No filters
- Very easy maintenance
- Good impact on the local economy
- No impact on the environment

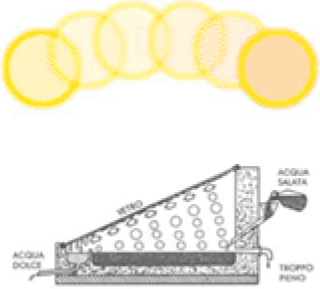
Eliodomestico

5 liters/day

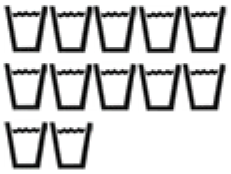


estimated cost: 50$

Normal solar still



3 liters/day



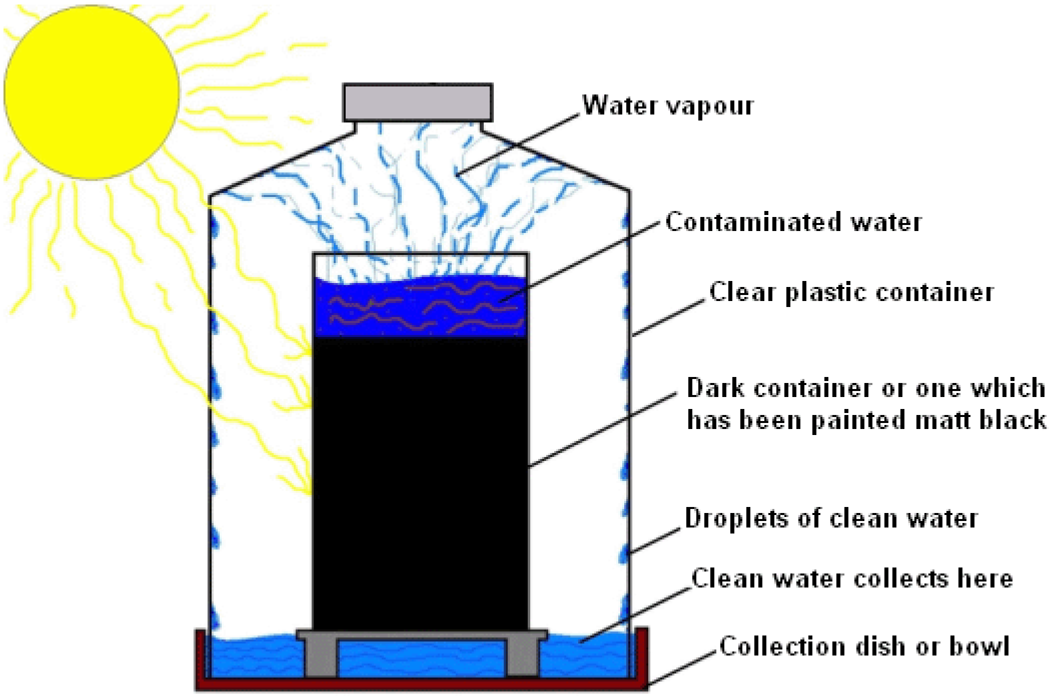
average cost: 100$

Eliodomestico is intended to be an open project

attribution - non commercial - share alike

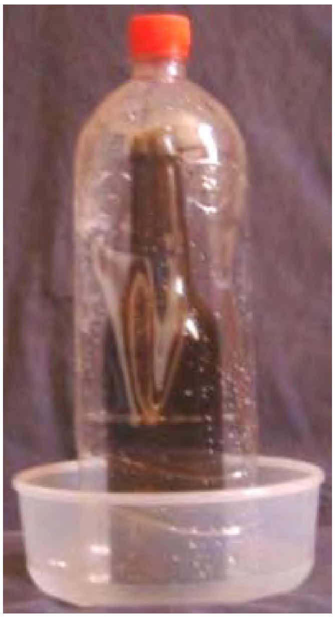
Very simple systems:

It is usually presumed that quite a bit of expenditure and construction is needed to make a solar still which will purify water. That is not necessarily the case. Here is a design which can cost nothing and which can work well in a sunny location:



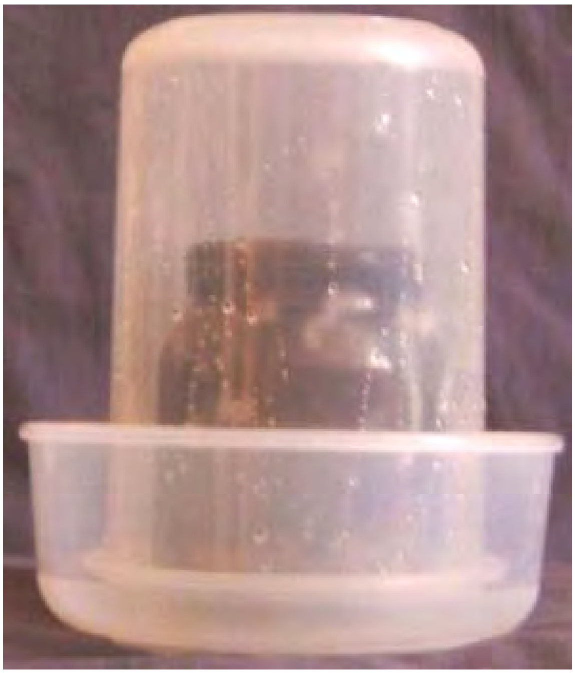
Water vapour
Contaminated water
Clear plastic container
Dark container or one which has been painted matt black
Droplets of clean water
Clean water collects here
Collection dish or bowl

This arrangement could hardly be more simple than it is. An inner container is used and it is made either from a dark material or is painted black, preferably, matt black as a shiny black reflects more of the light falling on it than a matt black surface does. In the diagram above, the black stops well short of the top of the inner container, but that is only to show the liquid inside the container and in fact, the inner container will be dark from top to bottom. Because of this dark colour, the liquid inside the inner container gets hotter than the air outside it (which is hotter than the air outside the outer container, due to the greenhouse effect). There is considerable evaporation from the inner container, but as it can't escape, it forms droplets on the inside of the outer container and these droplets slide down and collect at the bottom of the container, forming a reservoir of distilled water which is safe to drink. The construction of this still can be from things which are already to hand. For example, the bottom can be cut off a transparent plastic drinks bottle and used to cover a dark glass drinks bottle standing in an ordinary bowl, as shown here:

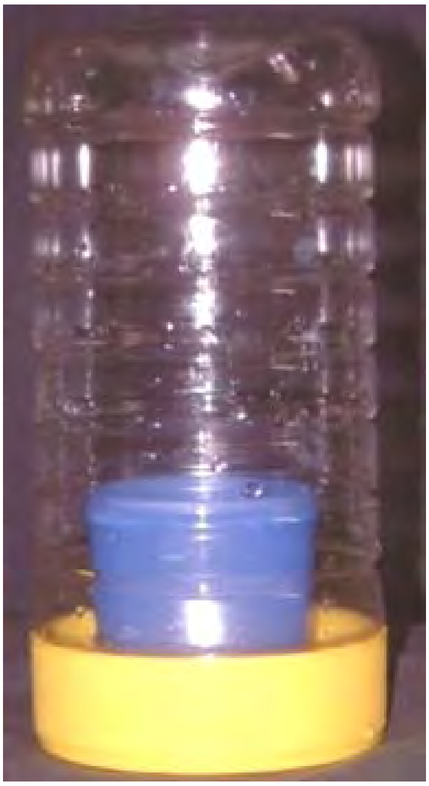


It is, of course, essential for the outside of the glass bottle and the inside of the plastic bottle to be completely clean so that they do not contaminate the purified water.

Another variation on this is to use a dark glass jar inside a plastic storage jar, again, placed inside an ordinary bowl as shown here:



Alternatively, a plastic jar with a screw lid can be used upside down and the lid used to replace the bowl. The inner container in this case, happens to be plastic. The capacity of the lid limits the amount of clean water which can be produced at any one time, unless the lid is carefully removed and a larger bowl used to catch the clean water (which means that it would have been easier to use the bowl instead of the lid):



Water Purity and Quality

There are two main factors involved in pure drinking water:

1. Debris and other non-biological material.
2. Biological material.

It is necessary to deal with each of these problems.

1. Non-biological material is avoided if the water is gathered by any of the evaporation/distillation systems shown above as the solids, sea-salts, mud or whatever, gets left behind. The same applies to collecting the evapotranspiration water from a tree using a clean plastic bag as mentioned above.

   If it is necessary to use stagnant, muddy water or water from a polluted river, then two things can be done. The first thing is to get the water as clean as possible before collecting it. If it is possible, dig a hole near the water supply, making the hole deeper than the bed of the river or pool. That causes the hole to fill partially with water coming from the source through the ground which acts as a filter and as a result, the water in the hole is likely to have a lower level of solids in it. Having extracted the water from the new hole, unless it is exceptionally good quality, it can be improved by filtering it through sand held in a cloth material, or even just through a fine-mesh cloth. Water can generally be found under the bed of a dried out river and the best point to dig is at the outside of a bend in the river bed.

2. Biological material is a serious hazard and it can make you very ill and/or kill you. The evaporation systems mentioned above, generally avoid this problem, but the safe method for producing safe drinking water is to boil it for at least ten minutes as that kills the organisms in the water, making it safe. Unfortunately, that requires a good deal of fuel and the water needs to cool afterwards. Mixing ozone into the water or shining ultraviolet light through the water are alternatives. Be very careful as even moistening your lips with contaminated water can make you severely ill.

   Water in a fast-flowing or bubbling stream flowing over rocks and sand, should be safe to drink provided that there is a stretch of 10 metres (30 feet) upstream of the sampling point, which is free from contaminants (dead animals, effluent inflow, etc.) as the movement of the water mixes air into the water and the oxygen in the air kills the bacteria.

   A very effective way of dealing with polluted water (and any illness caused by it) is to add some colloidal silver to it, as that deals with all serious pathogens and, for example, can totally clear a contaminated well. In case you are not familiar with how to make colloidal silver, details are given below.

Fresh water on a larger scale

US patent 2,996,897 (22 Aug 1961) from **Elmer Grimes**:

The fifty-year-old Grimes system is effectively an outdoor refrigerator. A series of cone-shaped metal panels are stacked together vertically to save space. Each cone has pipes inside it which pass the cooling fluid through the cones, ensuring that they are always at low temperature. In the same way that a cold drink gets water droplets on the outside of the glass, the cones get water droplets forming on them all the time. A wiper arm like a windscreen wiper on a car then brushes those droplets off, with the wiper arm rotating around the cones continuously, rather than backwards and forwards as a car wiper blade does. This produces a continuous stream of fresh water coming off the cones. Unless there is some good reason why not to, the cones are mounted in a raised position so that gravity can be used to direct the water flow to where it needs to end up. Cones are used as they have a greater surface area than a flat plate of the same diameter would have, and the downward slope of the cone helps the water droplets flow off the cone surfaces:

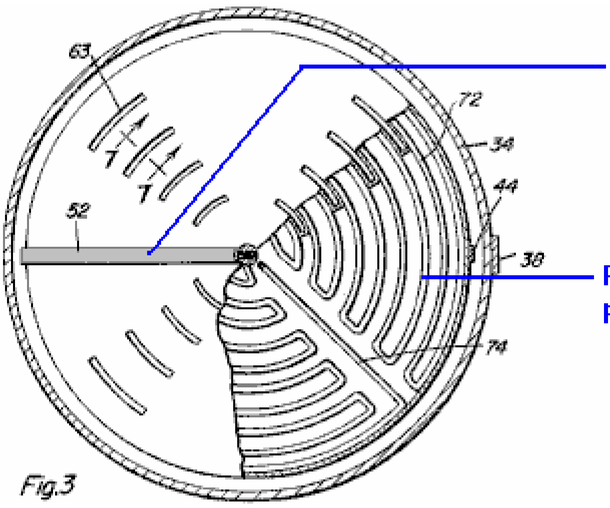


Fig.3

Wiper arm spins around wiping both sides of the cone surface

Refrigerant flows through these pipe which are inside each cone

ATMOSPHERIC WATER SUPPLY APPARATUS

This invention relates to a method and apparatus for obtaining a fresh water supply from the atmosphere. In arid and semi-arid regions, the supply of fresh water is a considerable problem which has in the past, been met by the use of highly expensive apparatus, equipment and systems involving the transport of water over great distances, using equipment which is consequently very vulnerable to destruction and additionally expensive in upkeep and repair. Other types of apparatus for obtaining a fresh water supply in such regions, involves the processing of sea water which has proven to be slow and also extremely expensive for obtaining water in larger practical quantities. It is therefore a primary object of this invention to provide apparatus which is especially useful in such regions for providing a fresh water supply in a more efficient, rapid and less costly a manner.

Another object is to provide a source of fresh water obtained from the atmosphere in a manner similar to a portion of the natural water cycle and by a process which avoids the high costl boiling, evaporating and pumping of sea water.

A further object is to provide an apparatus which removes water from the atmosphere by condensation and precipitation for use in home and commercial purposes having the advantage of providing a more local source of water which will be naturally soft, having no scale to clog plumbing, nor any disposal problem for salt and mineral matter as occurs with seawater.

An additional object is to provide apparatus for obtaining water directly from the atmosphere by condensing water vapour in the atmosphere on a number of conical condensing surfaces exposed to the air which may be cooled by the air if the air temperature is below the condensing temperature and automatically cooled by circulating refrigerant when necessary so as to provide means for continuously condensing on to the condensing surfaces, the water vapour which is in the air. Continuously operating wipers on the condensing surfaces cause the condensation on them to be swept into the bottom funnel portion of the apparatus. The water so collected is then conducted to local storage or use while the kinetic energy of the water flowing from the apparatus may be converted by means of a turbine-driven generator into useful energy which may be used to operate the motor driving the precipitation wipers as well as the compressor by means of which, the refrigerant is circulated within the condensing surface members for maintaining them at a temperature lower than the water vapour's condensing temperature.

It will therefore be apparent that the apparatus and method of this invention has the advantage of providing a continuous supply of water which may be so engineered to supply water at all times in sufficient quantities and at the same time, furnish the power for its own operation and even at times, excess power which may be used for other purposes. The apparatus and method take advantage of the potential energy acquired by water undergoing the natural waster cycle by prematurely condensing the water vapour in the atmosphere and mechanically precipitating it by a mechanism acting in concert with, and supplementing the natural phenomena.

Referring to the drawings in detail:

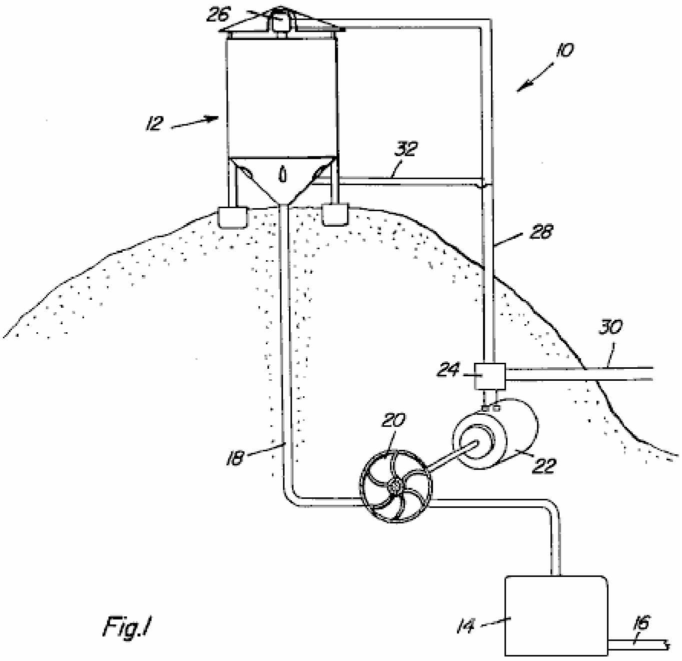

Fig.1

Fig.1 illustrates the installation set-up. The entire apparatus is indicated by reference number **10** and includes a tank structure **12**, (preferably) mounted at a height greater than the area to be supplied with the water. The water supply originates in the tank structure and is fed to the water reservoir **14** by a conduit system **18** which has a turbine **20**. A portion of the kinetic energy of the water flowing in the conduit **18** is absorbed by the turbine mechanism **20** which powers and electrical generator **22** from which electricity can be drawn via a voltage regulator **24**, which is connected to an electric motor **26** which is associated with the tank mechanism **12** by power lines **28**. The voltage regulator **24** is also connected to external power lines **30** which may be able to supply additional power to other equipment. On the other hand, the power line may be interrelated with the mains supply so that when the power output of the generator **22** is insufficient to energise motor **26**, and external source of power through the power line **30** may be used.

It will also be noted from **Fig.1**, that an additional electrical connection **32** is provided between the power lines **28** supplied either by the generator **22** or the external power source through line **30** and voltage regulator **24** so as to operate other parts of the equipment associated with the tank structure **12** as will be explained later.

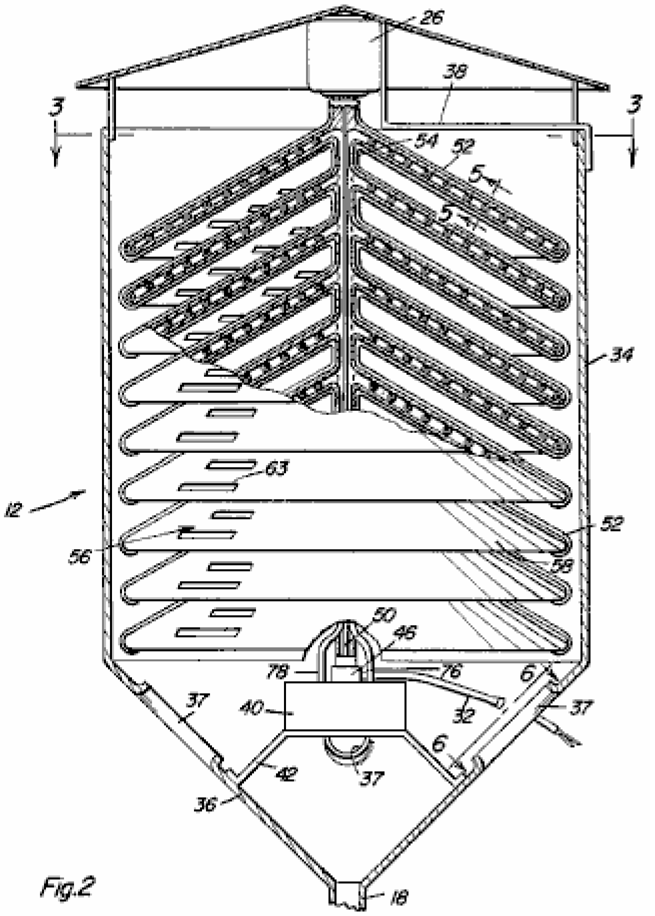

Fig.2

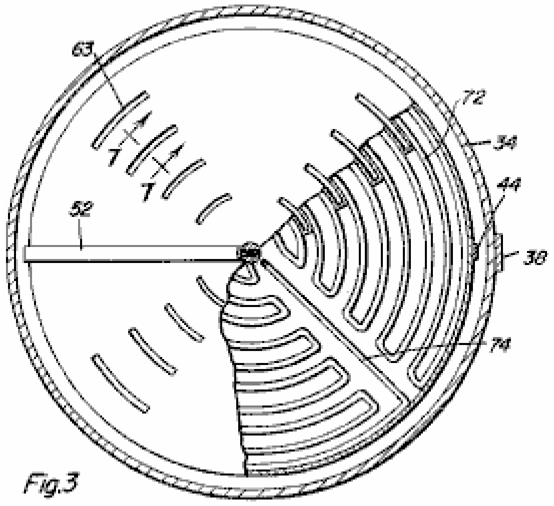

Fig.3

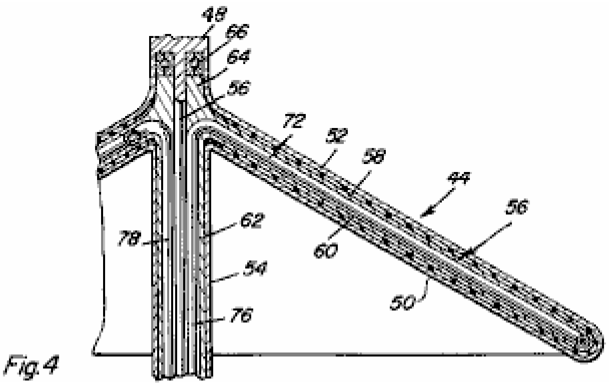

Fig.4

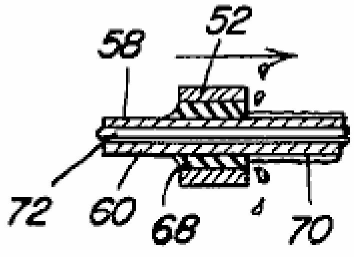

Fig.5

Referring now to figures **2, 3, 4** and **5**, it will be observed that the tank structure **12** includes a cylindrical portion **34** which is connected at the bottom to a funnel portion **36**, to which the conduit **18** is connected. Water collects at the bottom of the funnel **46** and carried by conduit **18** for storage and use. On the funnel walls are a number of streamlined-shaped openings **37** with upward projecting rims enabling the circulation of moisture-laden air through the funnel portion for additional water collection, each opening being designed however to prevent flow of water from the funnel portion as seen from **Fig.2** and **Fig.6**. It will also be observed that the motor **26** which is positioned above the open top of the cylindrical portion **34** of the tank structure **12**, is mounted on the cylindrical section **34** by means of a suitable mounting structure **38** while a refrigerant circulating unit **40** is mounted within the funnel portion **36** in axial alignment with the motor **26** by any suitable supporting structure **42**. In addition to the wiper of the unit **44** driven by the motor **26**, the compressor mechanism **40** is also driven from the motor **26** and is connected by a thermostatically controlled disconnector mechanism **46** of any suitable design, using mains power for connecting and disconnecting using lines **32** which are there for that purpose. The specific designs for mechanism **46** are well known.

It will be observed for **Fig.2** and **Fig.4** in particular, that the motor **26** has an output shaft **48** to which there is connected an elongated extension shaft **50** which extends downwards through tank **12** for connection to the compressor **40** through the thermostatically-controlled electrically-operated clutch **46**. Also connected to the motor shaft **48** are a number of interconnected wiper arms **52** of the wiper mechanism **44**. It will be observed from **Fig.2** and **Fig.4** that there are provided several parallel downward-inclined wiper arms **52** which are connected by axial connecting members **54**.

The wiper arms **52** are positioned around, and rotate with respect to, the cone-shaped parallel, vertically spaced apart, plates **56**, each of which has an exposed upper condensing surface **58** and a lower condensing surface **50** which are connected at their outer edge, and at their inner edge, they are connected to the next plates vertically above and below by plate **62**. As is more clearly seen in **Fig.4**, the plate members terminate at the top with an axial portion **64** with respect to which, the motor shaft **48** rotates, bearing **66** being positioned between motor shaft **48** and part **64** of the conical plate. Shown in **Fig.3** and **Fig.7**, lined curved openings **63** are placed in the condensing portions **58** and **60** of the conical plate members **56** in order to accommodate the circulation of air through and between the plate members. The plate members may be held fixed with respect to the housing tank **12** while the wiper arms **52** of the wiper mechanism **44** may be rotated relative to it. Accordingly, the wiper arm **52** includes wiper material **68** which contacts the upper and lower surfaces **58** and **60** of each of the conical plate members **56** so as to wipe from them the condensation **70** formed there as more clearly seen in **Fig.5**. The water so precipitated falls down to collect at the bottom of the funnel portion **36** of the tank **12**.

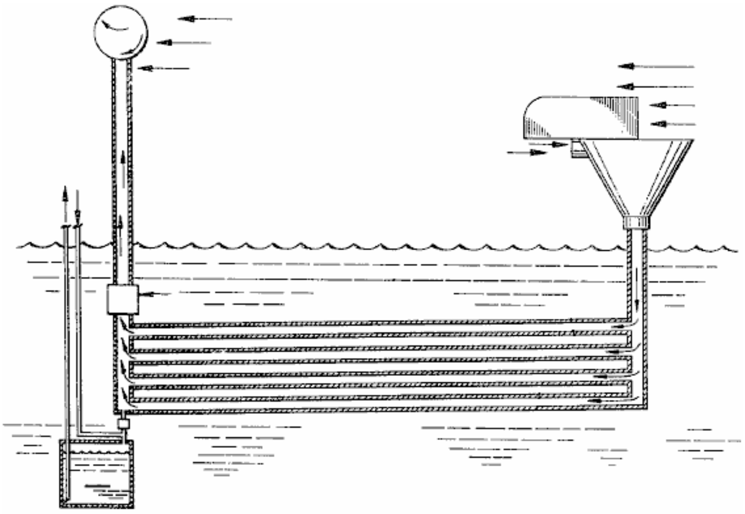
It will be understood that the water vapour in the air will condense on surfaces **58** and **60** if the temperature of the air is low enough, or below, the water condensing temperature. At certain times, such as at night, the air temperature will have the conducting surface at the proper temperature. However, at other times it will be necessary to cool the condensing surface artificially by use of a conventional circulating refrigerant system. Accordingly, circulating refrigerant coils **72** are placed inside each conical plate **56**.

As seen more clearly in **Fig.3**, the coils **72** are arranged to provide cooling for the entire exposed surface of the conical condensing plate **56** between the upper and lower condensing surfaces **58** and **60** of each conical plate member as more clearly seen in **Fig.4**, with the lined openings **63** being located between the coils. Each cooling coil network **72** is connected by a radial connecting tube **74** (**Fig.3**) connected to an axial tube portion **76** (**Fig.4**) through which refrigerant may be pumped into the coil **72** of each of the conical plate members **56**. The axial portion **76** of the cooling tube is connected at the bottom to the circulating unit **40**. Refrigerant under pressure is applied to the supply tube **76** for circulation through each of the conical plate members **56** and returned through a parallel axial tube **78** as seen in **Fig.2** and **Fig.4**.

It will also be understood that although the apparatus is described in the illustrated example with stationary conical plates and rotating wiper arms, it would be possible to have the wipers fixed and the cone rotating, and in that case the rotation of the cones may provide sufficient physical disturbance through inertia and centrifugal effect to cause precipitation, in which case the wipers will not be needed. Furthermore, the number of wiper arms may be varied to suit the conditions under which the apparatus operates and the quantity of water to be derived from the atmosphere. The wiper mechanism **44** which is operated by means of the electric motor **26** to which the compressor **40** is also connected, may for the most part receive its operating power from the generator **22** which in turn derives its power from the kinetic energy of the water flowing through the conduit **18**.

Also, the unit **40**, which in addition to the wiper mechanism **44** loads the motor **26** may have its load disconnected from the motor **26** for more efficient operation when the refrigerant is not needed, such as at night when the air temperature is low. Removing the compressor load may be done manually or automatically by the mechanism **46** shown schematically, and which may be electrically operated to disconnect the motor drive shaft extension **50** from the compressor of the unit **40** when the air temperature is low.

There is also patent 4,418,549 (1983) from **Calice Courneya**. In this method the cooling parts are buried underground as it is assumed that the ambient air will be at a higher temperature than that below ground. The passage of air through the apparatus is intended to be wind driven although the incoming air is filtered to remove particles before entering the apparatus. There is also the provision of an extractor fan on the outlet, presumably for when there is little or no wind.

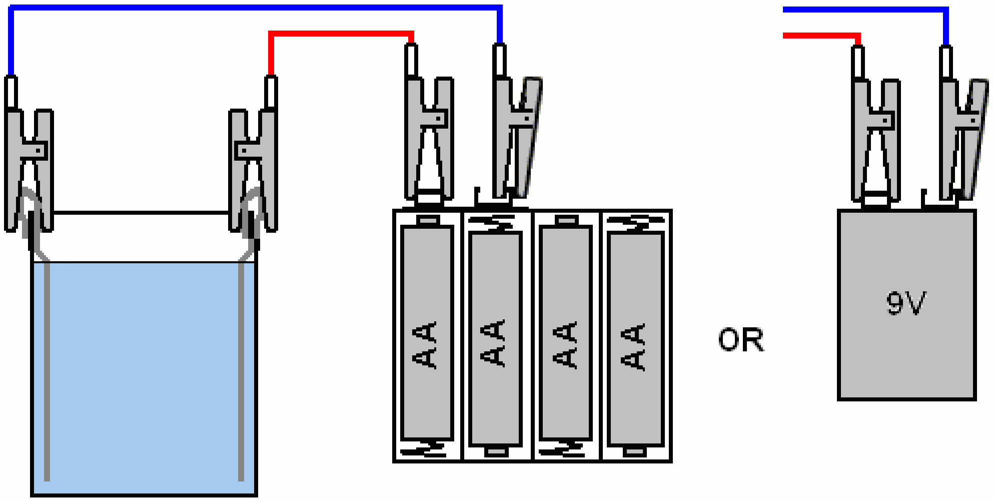


Another system is using a large Fresnel lens to distil water which is not suitable for drinking. This is possible using the most simple equipment of two glass bottles and a piece of copper tubing. If it is still there, the video at http://www.youtube.com/watch?v=aXjMAItCMl0 shows the method, though I must admit that I would prefer to take the liquid which he drinks and pass it through the system again to improve it's quality further.

Making Colloidal Silver

Colloidal silver is minute charged particles of pure silver suspended in distilled water. It is completely harmless to humans and has no side effects of any kind. It should be stored in a cool, dark place away from direct sunlight.

It is made using a glass container, some 99.99% pure silver wire and a battery:



Two clip wires are used to connect to the battery which can be 6-volt, 9-volt, 18-Volt or 27-Volt (by plugging two or three 9V batteries together). The other end of the two wires are used to clip the silver wire to the sides of the glass container holding the distilled water, holding the silver wire in place as well as making the electrical connection to the silver. Be sure that the distilled water does not cover any part of the clips as that contaminates the water as the clips are steel and not pure silver.

When the battery is connected, the distilled water is stirred gently for about fifteen minutes. The stirrer needs to be non-metallic – glass, plastic or wood, to avoid the stirrer becoming part of the processing and preventing the production of pure colloidal silver. The stirring is a very important part of the processing. The current flowing from the battery is very small and it is influenced by the separation of the silver electrodes.

The space between the electrodes can be adjusted by choosing where they are placed on the rim of the glass container. The particles taken from the silver wire are so tiny that the silver wire never seems to need to be replaced.

After a few minutes, the silver wire which is connected to the minus terminal of the battery, will become coated with a black substance. This needs to be cleaned off. I use a clean tissue for this. As time goes by, the rate at which the black coating develops increases as the water becomes much more able to carry current from the battery. Do **not** use any kind of chemicals to clean the silver – the purity of the water and the silver is vital. The silver wire connected to the positive terminal of the battery develops a dull grey coating which needs to be cleaned off occasionally.

I generally continue the process until I have cleaned off the negative electrode four or five times using a clean tissue. In passing, “colloidal” just means that the silver particles are too small to drop out of the water under gravity and so, stay dispersed throughout the water indefinitely. The end product should be clear and look exactly like water (which it mainly is). If you shine a laser light such as a lecturer’s laser pointer, into the colloidal silver, it looks very pretty, lighting up with thousands of little sparkles as the light is reflected off the silver particles in the water.

The most popular concentration is 10 Parts Per Million as that is a very effective level and that is the level typically produced after fifteen minutes of production. If you want to take it orally, then a teaspoon of colloidal silver held under the tongue for a minute before swallowing is recommended perhaps five times per day. Some interesting facts:

1. When Czechoslovakia was under communist occupation, Soviet intelligence came across a domestic disinfectant which was capable of neutralising not only their existing biological weapons, but also those under development. The Soviets quickly dismantled the factory which was producing this product and moved the equipment, documentation and even the staff to the Soviet Union. Following this, no one heard of the disinfectant again. In a study of infected wells, it completely destroyed typhus, malaria, cholera, and amoebic dysentery. This domestic disinfectant is a variety of colloidal silver.

2. Colloidal silver does more than just kill disease-causing organisms, it also promotes major bone growth and accelerates the healing of injured tissues by over 50%. It promotes healing in skin and other soft tissues in a way which is unlike any other known natural process. An example of this is the case of Glen Roundtree, a 32 year old man, who was clearing brush and trees in his parent's yard when some petrol left on his hands after filling the chain saw ignited. He burned for over 30 seconds as he tried to get the fire out. Glen suffered third degree burns on his hands and face. His mother's friend brought him some colloidal silver. He drank it and sprayed it on his face often. He was able to stop taking morphine immediately. Within three and a half weeks his recovery was so advanced that his hospital attendant did not believe he was the same burns patient. In less than three months his face was completely healed with absolutely no scarring. The planned re-constructive surgery for his melted nose and ear was cancelled.

3. In the presence of colloidal silver, cancer cells change back to normal cells regardless of their location in the body. The presence of silver ions regenerates tissues and eliminates cancer cells and other abnormal cells. For many years, Dr Bjorn Nordstrom of Sweden's Karolinska Institute has used silver in his cancer treatment methods. He reports that he has successfully cured patients who had been diagnosed as "terminally ill" by other doctors. He also discovered that the silver was promoting the growth of a new kind of cell which looked like the cells only found in children. These cells grew fast, producing a diverse and surprising assortment of primitive cell forms able to multiply at great rate and then change into the specific cells of an organ or tissue which had been injured, even in patients over 50 years old. In no case were there any undesirable side effects. He also discovered that previously untreatable osteomyelitis and bones which refused to knit, could be healed quickly by applying a silver-impregnated nylon dressing attached to a small battery. This worked so well that it has become standard practice today when dealing with bones which refuse to knit.

4. Dr Paul Farber suffered a tick bite which overnight, gave him the crippling Lyme's Disease. There was no satisfactory treatment so he searched medical literature to see if he could find anything to help. He finally found the comments of Dr Crookes about colloidal silver killing a microbe in six minutes or less. He also found the research and development work done on colloidal silver by Dr Moyer, Dr Bretano and Dr Margraf. Dr Farber started taking colloidal silver with spectacular results, clearing the bacteria out of his body in a short time - colloidal silver kills the Lyme's Disease bacteria.

5. Antibiotics have no impact whatsoever on viruses. This means that taking any antibiotic will have no effect on a viral infection. Worse still, many forms of bacteria are now resistant to most antibiotics. Colloidal silver will kill both and boost your natural immune system at the same time, and it cures AIDS and Ebola.

Agriculture

The Elmer Grimes system for extracting water from the air is able to produce volumes of water capable of supporting agriculture, even in dry areas such as Texas. While agriculture or food production is not part of this publication, there are a few things which should be mentioned. I know nothing about agriculture but I do know that soil of very poor quality can be converted to rich, productive soil by burning vegetation and then working the resulting ash into the poor soil. That requires no chemicals and is very low cost and effective.

Also, the effectiveness of a growing area can be boosted substantially by using vertical stacking. The company Agricube at http://www.agricube.co.uk has an effective, proven, low cost system for doing this with standard modules which stack on top of each other:

These stacking units can boost the effective growing area by a factor of five.

Trickier to operate but very neat in concept is the technique of hydroponics combined with fish farming. With that technique, the fish waste forms food for the plants and the plants draw the waste from the water, keeping it fresh for the fish. It is a very effective system and there is a free download manual on this at http://www.fishplant.co.uk/ where fish selection is explained as well as how to operate the system in family size or commercial scale. Useful video at https://www.youtube.com/watch?v=HYR9s6chrI0.

Kimbal Musk’s “Urban Farming Accelerator”

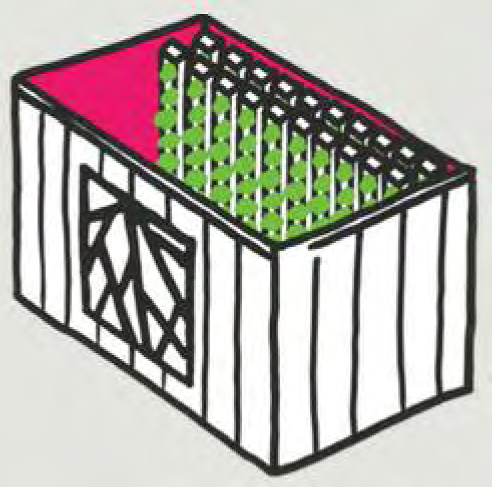
By Justin Gardner 29th August 2016

The demand for real, local food is growing as more people become aware that agribusiness corporations such as Monsanto, along with lobbying groups like the Grocery Manufacturers Association, have a frightening grip on America’s food system.

“Big Food” would rather have everyone continue to eat highly processed, mass-produced substances packed with genetically modified fillers and artificial ingredients.

The surge in organic and non-Genetically Modified sales is a heartening reminder that the power of the purse can make a difference. Farmer’s markets, where people congregate to buy real, nutritious food and meet the farmer who produces that food, have grown all over America but the availability of real, local food is limited in urban areas, where communities often experience “food deserts” where the only things available are the unhealthiest processed substances of the Big Food industry.

Kimbal Musk (brother of the innovating entrepreneur Elon Musk) and his colleague Tobias Peggs are looking to change that by bringing real food production into the heart of urban areas. This autumn they are launching Square Roots, an “urban farming accelerator” centered on the use of modular shipping containers to grow the equivalent of two acres of food year-round. It’s not just a box, though, but an initiative to join the energy of youth with healthy, sustainable solutions to food production.



“Square Roots builds campuses of climate-controlled, indoor, hydroponic vertical farms, right in the hearts of our biggest cities. We train young entrepreneurs to grow fresh, local food all year round. And we empower them to create forward-thinking, responsible businesses that strengthen their communities through real food. All this means year-round heaven for local foodies. From farmer’s market conversations to farm-campus parties, from speaker series’ to digital content, Square Roots creates opportunities for everyone to dig into local food – even if there’s two feet of snow on the ground.”

With technology and urbanisation, people have unfortunately been losing touch with the basic knowledge of where food comes from and how it is grown and made – which makes the system ripe for abuse by corporate interests and government lackeys. Square Roots is a brilliant counter to this trend. It not only puts power back in the hands of the people, but also creates opportunity for activities that contribute to the health of body and mind. Gardening is known to make you smarter and happier.

Last week, Kimbal Musk explained why he is “empowering thousands of young people to become #realfood entrepreneurs through Vertical Farming”. He says “strong communities are built around local, real food. Food we trust to nourish our bodies, the farmer and planet. This is #realfood. Sadly, many people in our biggest cities are at the mercy of industrial food. The industrial food system ships in high-calorie, low-nutrient, processed food from thousands of miles away. It leaves us disconnected from our food and the people who grow it. As Michael Pollan and others are have pointed out, the results are awful - from childhood obesity and diabetes to a total loss of community in our food”.

For a decade, Musk's startup called "The Kitchen" has served real, local food to millions of city residents, while getting kids interested in real food through 300 Learning Gardens across the country. Square Roots will naturally build on this success.

"Leveraging proven technologies like Freight Farms and ZipGrow, Square Roots' vertical farms are literally built inside shipping containers. They essentially enable three-dimensional growing - giving farmers the annual yield equivalent of two acres of outdoor farmland inside a climate-controlled module with a footprint of barely 320 sq. ft. These systems also use 80% less water than outdoor farms. That's the potential for a lot of real food grown in a very small space using very few resources. Best of all: vertical farms can be installed in the middle of cities. Our urban campuses will have anywhere from 10 to 100 farms. Using this platform, Square Roots entrepreneurs can avoid almost all the transport-impact of the industrial food system - by growing real food, at scale, right next to people who want to eat it".

Their first campus will debut in Brooklyn, New York this autumn, and they admittedly "have a lot to prove" in the beginning stage. But all indications point to a huge demand for real food in urban areas, and plenty of young entrepreneurs ready to merge their business drive with sustainable solutions for the planet.

Toribio Bellocq's Water Pump.

A serious problem for farmers and individuals is the cost of pumping water up from a borehole or well. While the combined Lever / Pendulum system of Veljko Milkovic described in Chapter 4 can reduce the amount of effort required by a substantial margin, there are other methods which could be useful.

It was originally thought that water could not readily be pumped to a greater height than 32 feet or so unless the pump was located at the bottom of the pipe. Toribio Bellocq demonstrated in 1924 that this is actually not the case and that water can be pumped to any height using a pump mounted at the top of a vertical pipe. He showed a working system to the Patent Office where an 80-foot vertical pipe was used to demonstrate the principle and having proved the point, he was granted US Patents 1,730,336, and 1,730,337, and later, US Patent 1,941,593 in which he describes chamber devices which can enhance the sonic wave operation.

Toribio's system is very straightforward. He places a one-way ball valve at the bottom of the vertical pipe (item **V** in the diagram below). A crank rod is then used to vibrate piston **C** in its pumping cylinder. The pumping cylinder has no valves and the piston stroke is very short. Both the pipe and the pump cylinder are filled with water before the operation is begun.

The rapid movement of the piston creates a pressure wave in the water in the pipe. The pressure wave causes the water pressure inside the pipe to rise and fall rapidly. This altering water pressure at the one-way valve at the bottom of the pipe, causes water to be drawn into the pipe when the pressure is low and the valve prevents the water flowing out again when the pressure rises.

This repeating action causes water to be pumped up the vertical pipe and out through an adjustable valve **R**. When the pumping action is timed correctly, there is an almost continuous flow of water from the pipe.

Toribio quotes an example in his patent, where the vertical pipe has an internal diameter of one inch, placed in a well where the water is twenty metres below the ground level. The valve opening is 30 mm and the sealing ball of the valve has a diameter of about 38 mm and contained in an ordinary cage which allows some 20 mm of vertical movement of the valve.

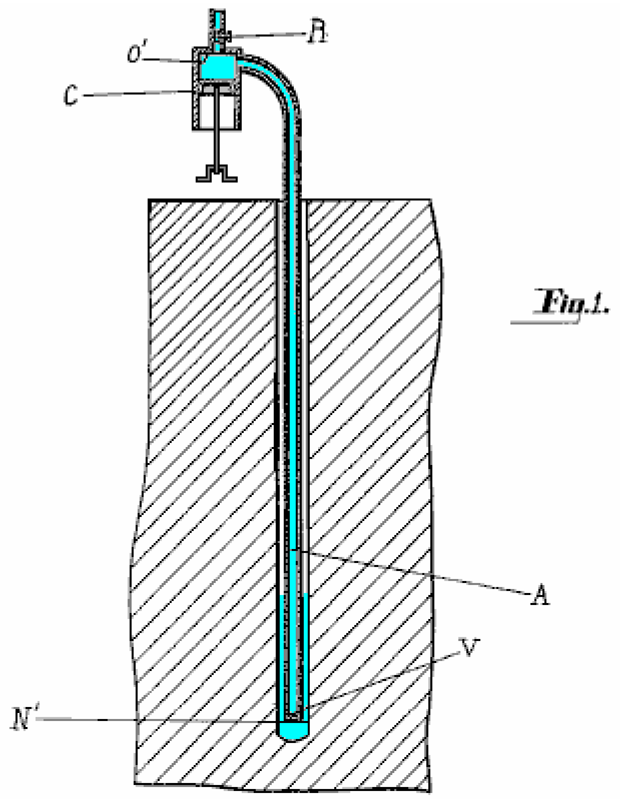


Fig.1.

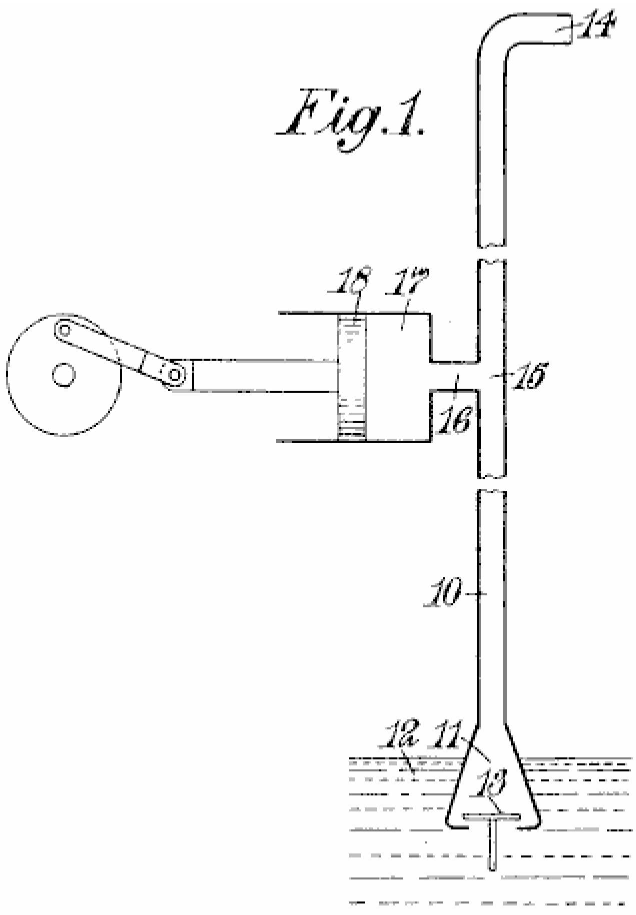
With this arrangement, the piston at the surface has a diameter of 50 mm and a stroke of 38 mm and is driven by an electric motor at about 360 rpm. The outflow pipe has an internal diameter of half an inch and the valve **R** is used to control the rate of flow out of the system. When the valve is adjusted correctly, a continuous flow is achieved and the flow rate is about 1,000 litres per hour (265 US gallons per hour, or 220 Imperial gallons per hour). It is important that the initial filling of the pipe and fully-open piston avoids getting any air trapped along with the water. The compressor cylinder can be horizontal or vertical. The well can be of any depth and there is no need for the pipe to be straight or vertical. When the system is adjusted correctly, there is little or no wear on the valve at the bottom of the pipe. The liquid pumped does not have to be water.

Richard Dickinson's Water Pump.

US Patent 2,232,678 of 1937, show a very similar system with a piston being driven in a cylinder without valves, creating a pressure wave in the vertical pipe which has a similar one-way valve at the bottom of the pipe. Interestingly, no mention of Bellocq's patent is made. Dickinson's patent drawing of the system outline is shown here:



Arthur Bentley's Water Pump.

The grandson of the car designer, Arthur Bentley has some 34 patents to his name, one of which (US 4,295,799) is very much like Toribio Bellocq's pump system. Richard Bruner writing in the Calgary Herald newspaper in 1989, tells how a prototype of the Bentley design was tested on a Navajo reservation in Arizona. Driven by four solar panels, a flow rate of 120 US gallons per hour was achieved, (about half that of Bellocq's rate at 20 metres depth), though the depth of the Navajo well was not mentioned. The manufacturers claim that the pump can operate at depths of up to 4,000 feet.

Neither this Bentley patent nor his earlier patent 3,804,557 makes any mention of Bellocq which seems somewhat strange, especially with the marked apparent similarity between the designs. Again, we see here, a piston being used to generate an acoustic wave in the vertical pipe and a series of one-way valves at the bottom of the tube being used to trap the rising column of water and prevent it from flowing out of the bottom of the pipe again. A variation in this patent is the addition of a spring loaded bottom section to the pipe which is alternately compressed and expanded by the sound waves as part of the pumping process as shown in the following diagrams:

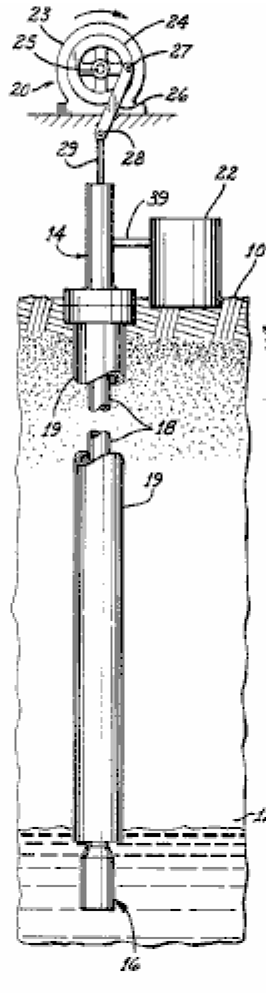


Fig-1

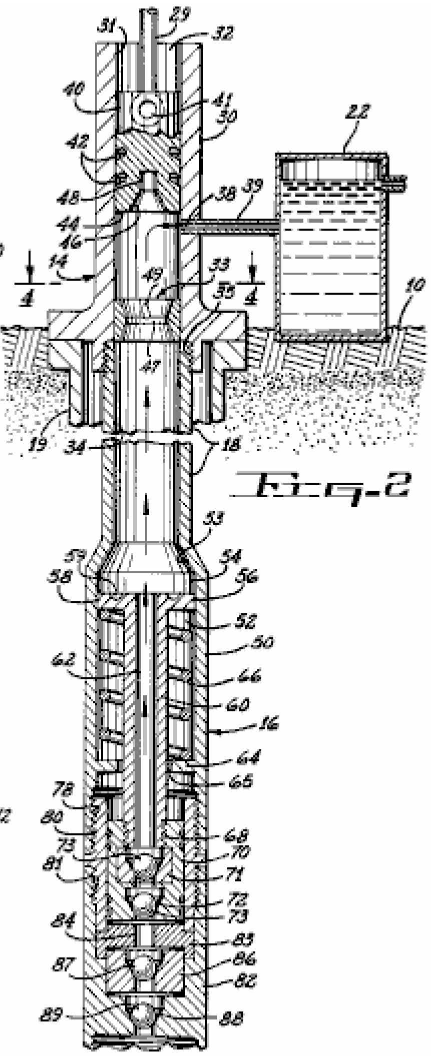

Fig-2

The Ram Self-Powered Pump.

In hilly areas, it is frequently necessary to pump water up to locations where it is needed. These locations are usually considerably higher than the source of water. There is a simple device called a "Ram Pump" which is powered by water flow alone and needs no other form of power. In a way, it operates very much like the pumps just described, in that water flowing into a pressure chamber causes fluctuating pressure which with just two valves, and no other moving parts, pumps water to a considerable height.

A Ram Pump can be used if there is a fast-flowing stream of clean water, and more than 50% of the water flow into the pump can be lifted to a higher level. The remainder of the water flows back into the stream at a point lower down. These pumps are readily available commercially and interestingly, they have a COP of infinity as the user does not have to supply any input power and yet substantial pumping power is produced for an unlimited period. As this is a standard Engineering technique, nobody gets upset at the though of 'perpetual motion' or 'free-energy' even though the pump can go on pumping for years with absolutely no fuel being burnt. This is energy being drawn from the environment in the same way as a self-powered compressed air engine draws energy from the environment, and yet, the compressed air engine is considered to be "unbelievable" while the Ram Pump is accepted without question. Could there be a certain degree of bias being seen here? The power operating the pump comes from the water flowing down hill. The water arrives at this height by falling as rain. The rain gets up there by evaporation caused by water being heated by the sun. So, bottom line, the pumping power comes from the sun.

If a fast-flowing stream is not available but the terrain allows it, then a Ram Pump feeding system can be built. Ideally, there should be a drop of at least two metres (six feet) on the inlet pipe. This creates a fast flow into the pump by feeding it through a steeply sloping intake pipe, like this:

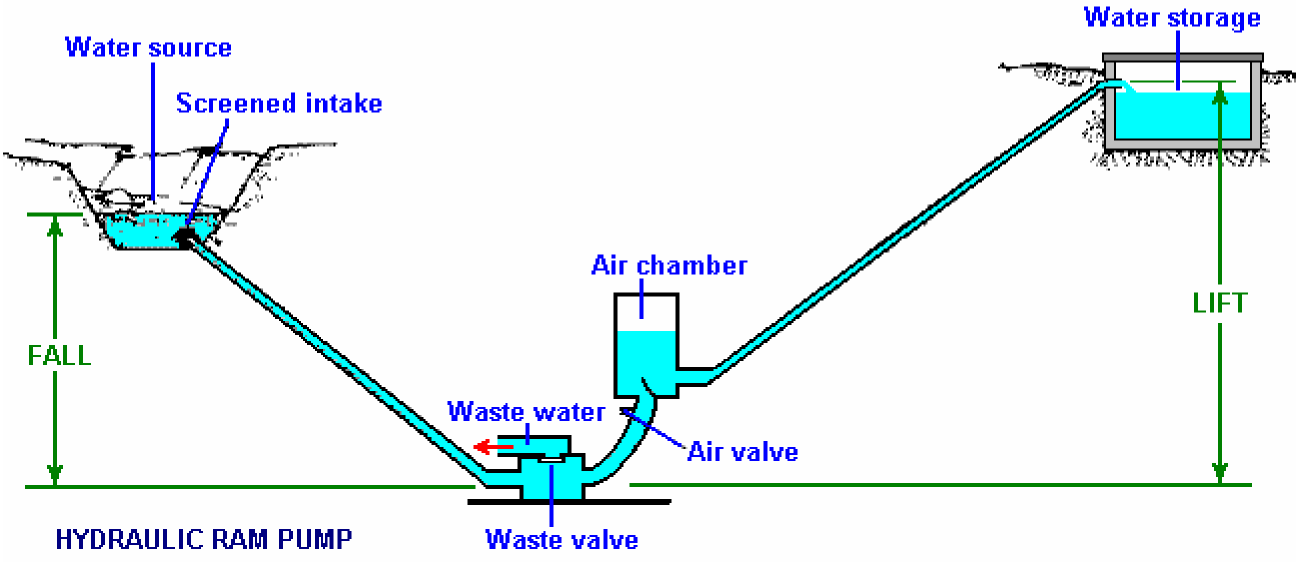

Diagram from: www.thefarm.org/charities/i4at/lib2/hydrpump.htm

The performance of a Ram Pump is impressive even though it has only two moving parts. With an input fall of just four metres and a small flow rate of just three litres per minute, a Ram Pump can deliver 69 litres per day to a massive height of 100 metres vertically above the pump. Or, 159 lpd to 60 metres above the pump, or 258 lpd to a height of 40 metres above the pump. This is impressive for such a simple device.

It operates by the water rushing into the air chamber. This raises the pressure until the valve at the base of the chamber slams closed. The increased pressure in the chamber pushes water out of the delivery outlet, lowering the pressure again. While this is happening, the closed valve causes a ‘water-hammer’ wave of reverse pressure which pushes excess water out of the ‘waste’ pipe and pushes water back up the intake pipe. When the pressure wave in the intake pipe dissipates, the water rushes back down the pipe, pushing the valve at the base of the air chamber, open again, to repeat the cycle. This oscillating pressure wave causes the pumping action, very much in the same way as the previous pumps which use a mechanical oscillator pump as no free-flowing water is available to create the oscillation.

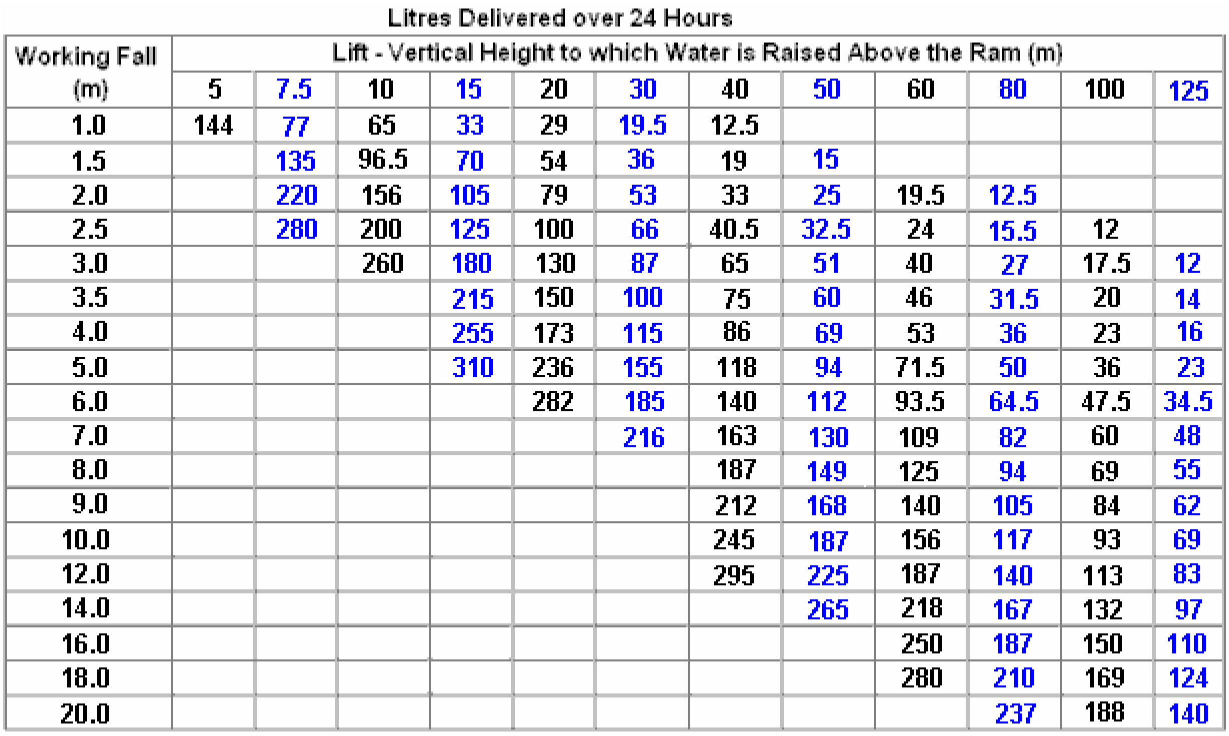
Commercial ram pumps have an efficiency of about 66%. The calculation of performance is:

$$\mathbf{D = (S} \times \mathbf{F} \times \mathbf{E) / L}$$

Where:

D = The quantity of water in litres delivered in 24 hours.
S = The quantity of water, in litters per minute, fed to the pump.
F = The height in metres of the water source above the pump intake.
E = The efficiency of the pump (assume 33% for home built units).
L = The height in metres, of the supply outlet above the pump.

Reproduced here by kind permission of US AID 1982 from the web site shown in the diagram above, is a table of values, calculated from the formula above, and assuming the 66% efficiency of a commercial unit. The input flow for these numbers is a tiny 1 litre per minute trickle. This is less than the hydroxy gas rate produced by the Smack’s Booster shown in Chapter 10, so in practice, you will be multiplying the numbers in this table by a realistic number of inflow litres per minute.



Litres Delivered over 24 Hours

Discouraging Mosquitoes and Small Flies

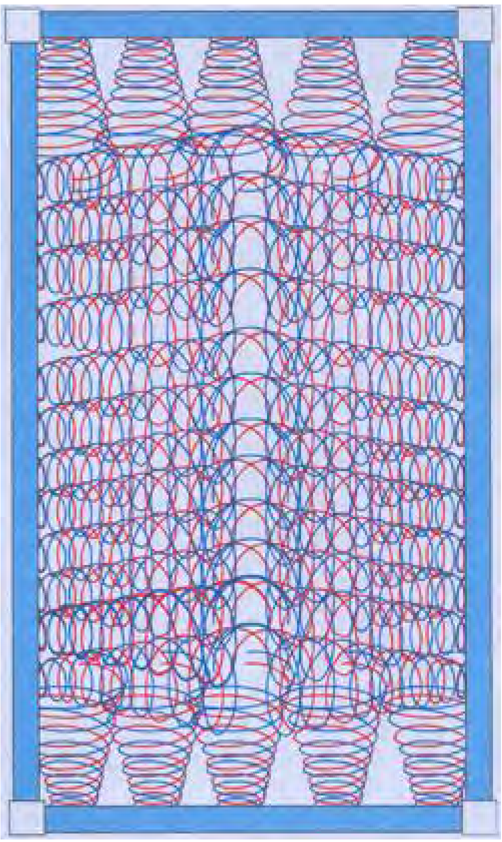
Maurice Cottrell (whose work is in chapter 11) presents what is a quite remarkable effect. He says:

Can you guess what it is?

What it is, is a church door in Ireland, surrounded with a white plastic pipe filled with water. When in Palenque in Mexico Maurice found that the local people discouraged flies, particularly mosquitoes and very small flies, by hanging polythene bags filled with water, from the lintels of their open doors. They do not know why, but doing that discourages flies from entering the doorway.

Maurice considered the effect and his opinion is that small flies can be injured by raindrops and so they have learned to avoid them. A falling raindrop has an electrogravitic effect due to the hydrogen atoms in the water, and flies which can see in the ultraviolet spectrum, can detect that effect around water and their instinct makes them avoid water – whether falling as droplets or not. Large bluebottle flies do not seem to be affected, but there is a definite effect with smaller flies.

If a doorway is surrounded with a 1-inch (25 mm) diameter plastic pipe filled with water, as seen in the picture above, then Maurice believes that the resulting effect is like this:

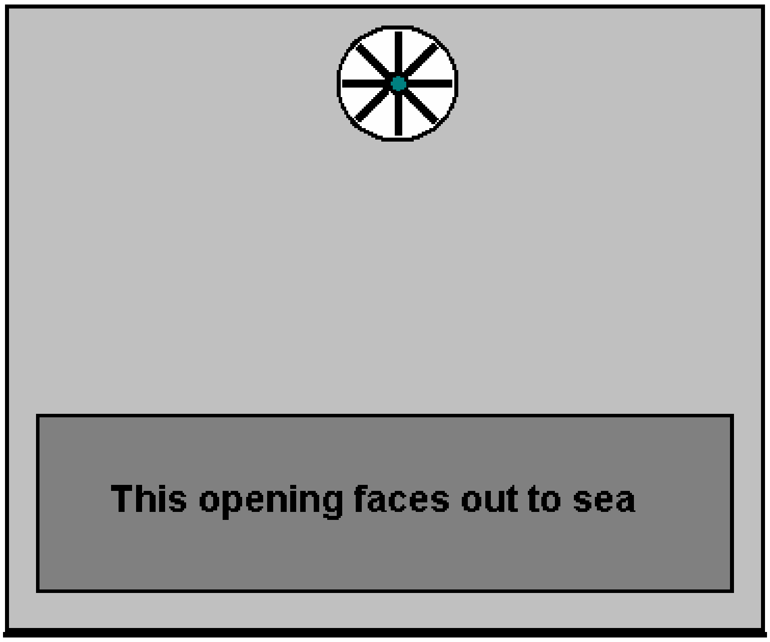


Here, gravity waves spread out from the water and create an effective barrier all the way across the doorway, discouraging the smallest flies, including midges. Obviously, any opening can be surrounded with a water-filled pipe, and not just doorways. While this is not a renewable energy device as such, it is a method which could well be useful where serious diseases are carried by mosquitoes.

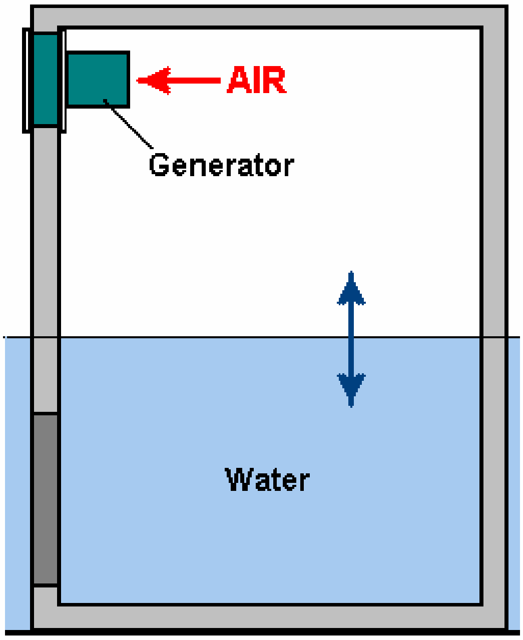
Wave Power.

Although not generally thought of as an option for personal use, wave power does have a high potential, although, like wind power and unlike tidal power, not always available. We tend to think of wave power systems as being large scale and very expensive, but that is not always the case. At it’s most basic level, most wave power system uses the varying distance between the surface of an ocean or sea and some fixed point on land or the sea bed.

Ideally, there should be a minimum of moving parts. One neat design uses a simple rectangular concrete housing with an electrical generator mounted above sea level. The generator being above sea level is easy to reach for maintenance or replacement and there are no moving parts underwater. It is a very simple design which can be built quite easily. In it’s most simple form, it is just a rectangular box with an underwater opening:



FRONT VIEW

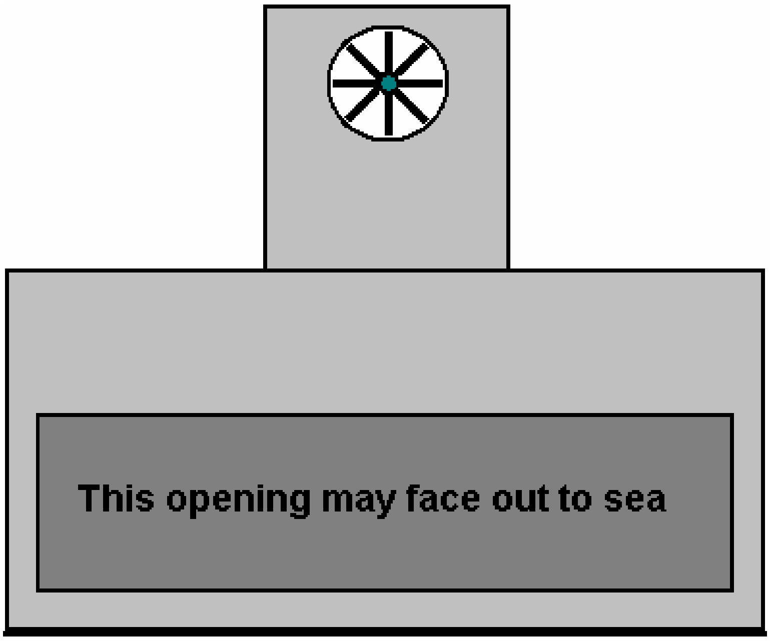


SIDE VIEW

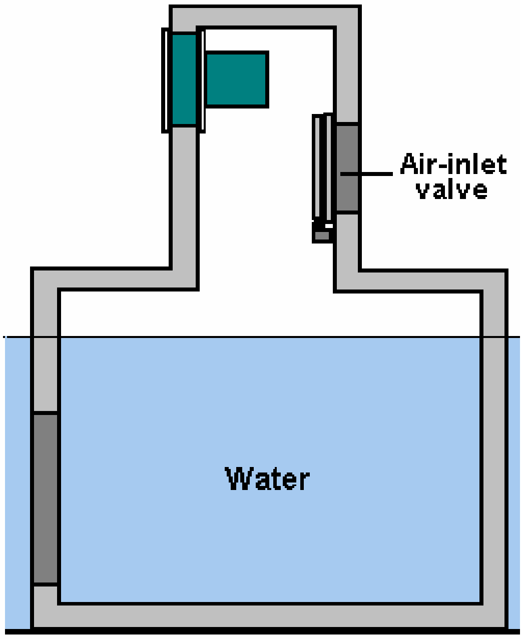
Here, a large opening allows the sea to flow into the structure which makes the water level inside the box move up and down with the wave motion outside. As a wave passes by, it compresses the air inside the box and the air is driven out through the generator opening, spinning the generator blades in the same way as a wind-powered generator has it's blades spun by the wind.

Some generators operate well with the air flowing backwards and forwards through the blades, generating electricity no matter which way the blades are spun. With a generator which works better with just one direction of spin, then a large flap valve is installed and it allows air to flow into the structure when the water level is falling but closes immediately the water level starts rising again.

Even though this style of wave power generator is so simple, it works very well in practice, provided that the vertical dimensions are arranged so that the top of the underwater opening is below the lowest neap tide and the bottom of the generator opening is above the highest spring tide. A baffle arrangement can be used to protect the generator from spray and storm debris. There is no need to have the structure full width above the water level:



FRONT VIEW



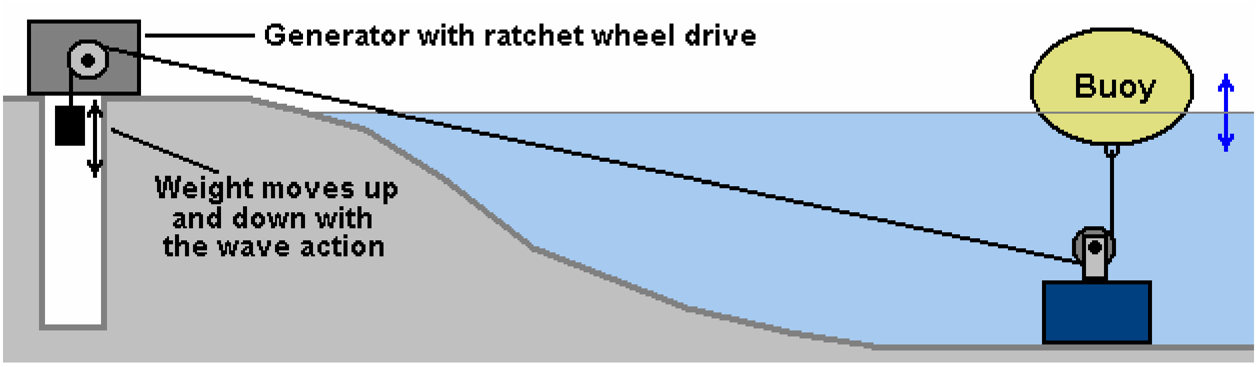
SIDE VIEW

This has the very considerable advantage that the area of the water surface inside the structure is very much larger than the cross-sectional area of the generator housing column and so the air rushes out through the generator much faster than the wave rises. This amplification factor can be increased by increasing the length of the base of the unit, further enlarging the water surface area inside the structure. If wave action is frequently very strong, then it may be preferred to have the undersea opening facing inshore or sideways in order to reduce the amount of material driven into it by very strong surges.

Another fairly simple wave power generator system design which is based on simple principles, was suggested on Stefan Nystrom's website which has been discontinued. It is called the "WaveReaper" system. It operates using a large number of separate buoys. Plastic barrels are suggested as suitable buoys but almost any non-dangerous containers which will not corrode in the sea and which have a considerable internal volume, can be used in this system.

Each basic unit consists of a float, a pulley, a cable and a ratchet drive connection to the shaft of an electrical generator. The power provided by the movement of the buoy can be very substantial as sea water weighs a considerable amount. The connecting cable is kept taught by a heavy weight, and the cable runs over a pulley which is mounted on a shaft which connects to the shaft of the generator. Bicycle parts are suggested for this section of the drive as they are cheap and readily available in most places and they come with a toothed sprocket wheel which already has a suitable ratchet built into it.

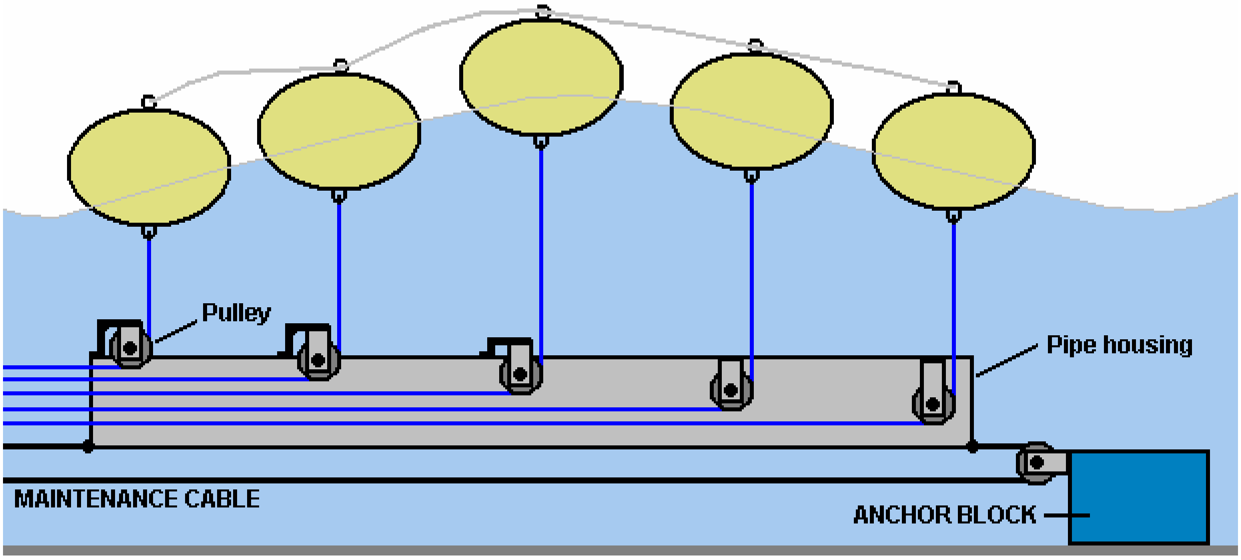
The reason for the shaft is that a whole series of buoys are used. These buoys are positioned progressively further and further from the shore so that an incoming wave raises the buoys one after the other in a regular sequence. This means that while one buoy is letting its cable run back inshore (pulled by it's inshore weight), one or more of the other buoys will be rising and applying drive to the shaft linked to the generator. This arrangement allows the generator shaft to receive a continuous drive. Having a heavy flywheel on this shaft is an added advantage as it will smooth out the repeated drive strokes provided by the buoys:



Generator with ratchet wheel drive
Buoy
Weight moves up and down with the wave action

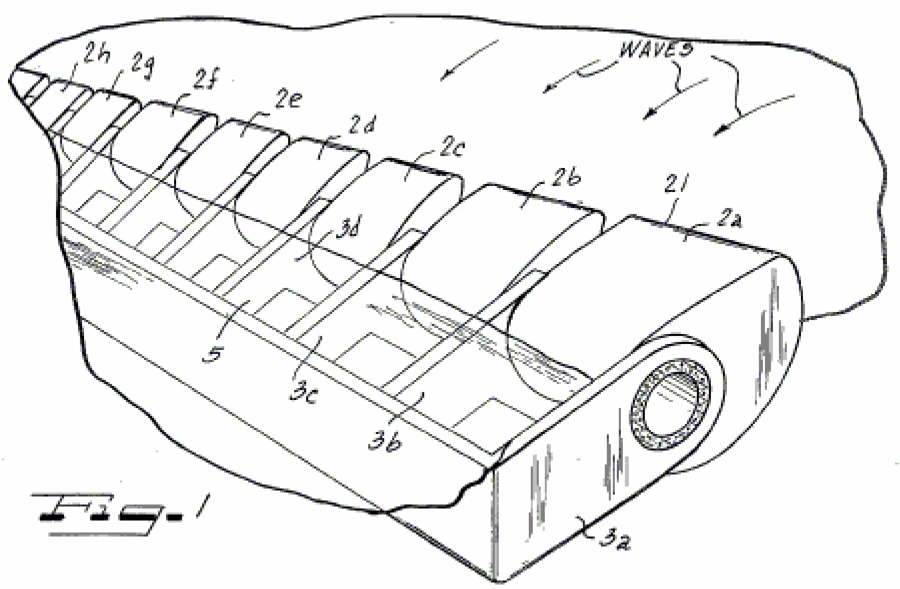
Having a sheaf of moving cables threaded through the sea near the shore is asking for a major tangle with seaweed and all kinds of other drifting material. Very sensibly then, Stefan suggests that the cables be housed in a protecting pipe. Considerable care needs to be taken to make sure that the cables do not rub against anything as the movement is constant and the forces involved are high. Each cable needs to have it's own space keeping it clear of all the other cables and having a pulley mounted at any points where there is a change of direction.

To make maintenance easier, it is also suggested that these protecting pipes are not fixed in position but are themselves on a pulley system so that they can be hauled ashore:



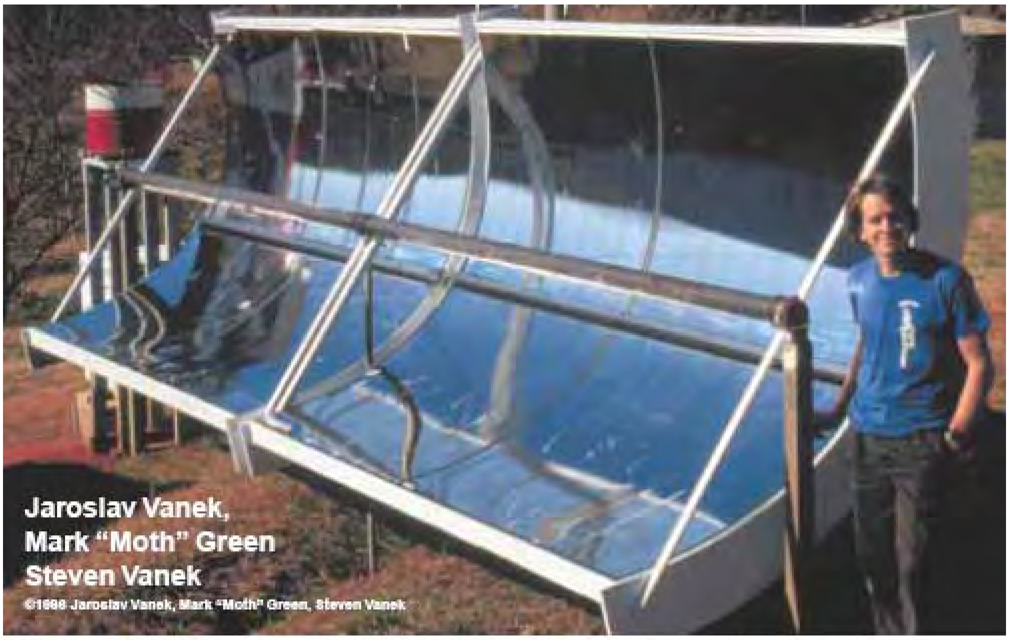
The buoys are also linked together loosely on top with a securing cord so that they always stay in a compact group, though there is little chance of any great sideways movement as the tension in the buoy cables is high. Stefan requests that anyone who constructs his design makes a donation via http://www.o2gruppen.se/ though how that is done is by no means clear to me as there does not appear to be a "Donate" button on that website.

There are many other wave-power devices, some with excellent efficiencies, but most are not generally capable of construction by the average amateur. One example is the "Nodding Duck" design by Stephen Salter of Edinburgh in Scotland, and shown in the US patent 3,928,967 where the wave power is extracted by a raft-like construction with cam-shaped floats. These floats have a rippling movement on the surface of the water and the movement of each section relative to the other sections is used to generate power. This is not exactly a back-yard construction.



Other Systems.

Not included in this eBook, but on the website http://www.free-energy-info.tuks.nl/ there are articles from the highly recommended Home Power website http://www.homepower.com/home/ which are on this general topic. There is a system for producing blocks of ice using sun power alone and no other energy input at all:



Above: Steven Vanek with his machine which uses solar thermal energy to make ice.

Also, a two-part article on Solar cooling, which concentrates on heat absorption with different colours, the strategic positioning of buildings and vegetation, practical roof overhangs and the like, to lower the temperature inside buildings in very hot locations.

There are articles is on cooking with hydrogen, heating your house with hydrogen and using hydrogen with a barbecue. On the Home Power site there is information on how to use solar power to heat household water and you may find the Google video on how to make your own hot-water solar panel interesting and useful. It makes sense to reduce your essential costs by doing a few simple things which help.

Cooling Using Heat.

Most of our current refrigerators use electricity to drive a compressor to achieve cooling. Here is a patent from Albert Einstein (whom you may have heard of) and Leo Szilard which uses heat to power refrigeration instead of electricity. It is US Patent 1,781,541 titled "Refrigeration" and dated 11th November 1930.

Our invention relates to the art of refrigeration and particularly to an apparatus and method for producing refrigeration where the refrigerant evaporates in the presence an inert gas and more particularly, to the type disclosed in the Von Platen and Munters Patent No. 1,685,764 of 25th September 1928 and our British Patent No. 282,428.

The objects and advantages of our invention will be apparent from the following description considered in conjunction with the accompanying drawing which shows more or less diagrammatically, a preferred embodiment of our invention.

In the drawing, **1** is an evaporator which is normally placed inside the chamber which is to be cooled. A pipe **5** connects the upper part of evaporator **1** to the more intermediate portion of the condenser **6**. Pipe **11** connects with the bottom of the evaporator **1** and extends into the condenser 6, at a level which is below the level of pipe **5**. A cooling water jacket **12**, surrounds the condenser and allows cooling water to flow through it.

Pipe **27** connects the bottom of the condenser **6**, to the lower part of a heat-exchanger jacket **28**. The upper part of jacket **28**, is connected to the lower part of generator **29** which is heated by any suitable method. Pipe **30** connects the upper part of generator **29** to a point near the bottom of evaporator **1** where it terminates in a distributor head **31**. Pipe **30** runs inside pipe **5** so that there is a heat exchange between the fluids in those two pipes.

Pipe **32** runs upwards from the lower part of generator **29** to connect with a container **33** which is positioned at a level which is above that of condenser **6**. A source of heat **36**, is applied to pipe **32** at a point above generator **29**. Pipe **37** runs down from container **33**, passing through the heat-exchanger jacket **28** and then on up to the top of condenser **6** where it terminates in a distributor head **35**. Pipe **37** runs inside the cooling water jacket **12** so that the fluid passing through it will be cooled as it flows. A venting pipe **34** connects the upper part of container **33** with the upper part of condenser **6**.

The operation of the apparatus is as follows:

A suitable refrigerant, for example, butane in liquid form, is held inside the evaporator **1**. An inert gas, such as ammonia, is introduced into evaporator **1** through pipe **30** and it's distributor head **31**. The refrigerant evaporates in the evaporator in the presence of the inert gas due to the fact that the partial pressure of the refrigerant is reduced thereby and the resulting gaseous mixture passes through pipe **5** and into condenser **6**. Here, the mixture comes into intimate contact with an absorption liquid, for example, water, which is fed into the condenser through pipe **37** and it's distributor head **35**. The ammonia gas is very soluble in water but the butane is quite insoluble, so the ammonia is absorbed into the water freeing the butane from the gaseous mixture. Thus, the butane assumes substantially the entire pressure inside the condenser, and that pressure is sufficiently high to cause its liquefaction at the temperature maintained by the cooling water.

The specific gravity of liquid butane is less than that of the solution of ammonia in water and so stratification of the two liquids occurs with the liquid butane floating on top of the ammonia solution **26**. The liquid butane passes from condenser **6**, through pipe **11**, and returns to evaporator **1**, where it is again evaporated and the cycle repeated.

Gravity causes the ammonia solution to flow from condenser **6** through pipe **27** and heat-exchanger jacket **28**, into generator **29**. Here, the application of heat causes the ammonia to be expelled from the solution in the form of a gas, which then passes through pipe **30** and distributor head **31**, into evaporator **1**, where it reduces the partial pressure of the butane, causing it to evaporate as already described.

Water, containing very little ammonia in solution, passes from generator **29** through pipe **32** where it is further heated by the source of heat **36**. This heating causes the formation of vapour in pipe **32** which lifts the liquid through this pipe and into container **33** and on from there under gravity through pipe **37** to condenser **6** and during its flow, this hot, low-concentration liquid is cooled by the heat-exchanger jacket **28**. It is further cooled by the cooling water in jacket **12**, and so reaches a condition where it can rapidly absorb ammonia in the condenser **6**. Vapour entering container **33** through pipe **32**, continues on it's journey to the condenser **6** via the venting pipe **34**.

During the operation of this piece of equipment, the pressure existing in the various components is uniform with the exception of slight differences caused by columns of liquid needed to cause the fluids to flow. The pressure existing in generator **29** must be sufficiently greater than the pressure in the upper part of evaporator **1**, in order to make vapour flow through distributor head **31**. In other words, the pressure difference must be sufficient to overcome the liquid head marked $\mathbf{h_2}$. This excess pressure in the generator is balanced by the pressure created by the column of liquid marked $\mathbf{h_1}$ in the drawing. This means that $\mathbf{h_2}$ must be less than $\mathbf{h_1}$, otherwise there would be no flow.

This patent of Einstein and Szilard seems to indicate that any source of heat such as a fire or a solar oven, should be able to produce cooling using a device which has no moving parts. It would probably be necessary to provide a trickle of water through the water cooling jacket, but apart from that, it looks like a device which could be used effectively by people who live "off the grid" and have little or no access to electricity. All in all, it is an interesting design.

Solar Panels.

A very well-know method of producing electricity from what appears to be a renewable resource is the use of solar panels. It hardly seems worth mentioning these as sales are so well promoted but it is possible that the problems with them are not understood. This used to be the most expensive way of producing electricity, but by 2015, electricity from free-energy and renewable energy sources have now exceeded the electricity produced by fuels such as oil, coal and nuclear energy. Much of this gain has been improvements in solar panels with a move away from the silicon wafer based technology to the newer thin film methods of construction. That lowering in cost made the new solar panels viable as an investment for speculators and that drove up the installed volume enormously, with solar farms supplying the existing grid and getting paid for their input. Schemes in Germany produce 7% or 8% for investors. Details of this can be seen in the 2008 presentation https://www.youtube.com/watch?v=mLHBFyfvK8A which explains the details very well.

What is often not realised is that solar panels have a working life span and will need replacement at some later date. The life is quite good, typically ten to twenty years, but the price of replacement must be allowed for. Solar panels are not the only part of your electrical system which will need replacing. Generally speaking, solar panels are used to charge batteries which then power equipment, usually by using an "inverter" which changes a DC battery voltage to a mains voltage AC supply. The big snag is that the frequently used lead-acid batteries generally have a lifespan of about four years. They are expensive, heavy and as they contain lead, they are not easy to dispose of (legally). This is a major recurring cost and disposal problem. The Tesla Car company has a high power 'battery' design capable of storing solar power and then run an entire household. At the present time, the unit is about 4 feet x 2 feet x six inches which is about 1220 x 610 x 150 millimetres and the price is around US $3,500. Hopefully, the size and price will both reduce considerably as manufacturing volume increases.

Another point which may not be realised with the older systems is that the current which can be drawn from a lead-acid battery without reducing its working life is very limited, quite apart from the fact that any lead-acid battery is only 50% efficient, requiring it to be fed twice as much current as it can supply afterwards. The safe discharge rate for a lead-acid battery is called the "C20" rate which just means that the allowable current is one which discharges the battery in a period of 20 hours. For example, if a new battery is rated as being a 100 Amp-hour ("100 AHr") battery, then the safe discharge rate is about 100 amps divided by 20, which is 5 amps. At twelve volts, a current of five amps is a power output of sixty watts. A washing machine needs about 2,200 watts for at least some of the time, so to power it (and nothing else at the same time) would take 37 of those 100 AHr batteries. Could you conveniently house 37 large batteries? How much do you think it would cost to replace them every four years?

Please understand that I have nothing against solar panels and actually own some myself, but you need to be aware of the practical problems with using them and not imagine that buying them will give you free electricity for ever afterwards.

The next factor to be considered is the fact that the power "rating" of a panel such as "120 watts" is not the amount of power which will be provided by the panel. It will provide that amount of power IF it is positioned exactly square-on to very strong sunlight in a region near the Equator. If the panel is not aimed exactly at the sun, then the panel output will be considerably lower. The sun moves around at a rate of fifteen degrees per hour, so your panel will only be aimed directly at the sun for about four minutes unless you have it mounted on a rotating platform and you push the platform round slowly to face the sun at all times. While that sounds complicated, it is actually not a difficult or expensive thing to arrange although most people don't bother to do that.

Even though most solar panels operate on UV rather than visible light, any minor cloud cover drops the panel output quite noticeably. There is also the little detail that most solar panels only work in sunlight or with reduced output in very bright daylight. This means half the day does not contribute to electrical input and in winter, when the electrical need is greatest, the days are shortest, sunlight scarce and daylight quality very poor unless you live near the equator. The level of sunlight which you will receive drops off steadily the further you get from the equator as the light angle gets lower and lower. This also causes problems in winter with quite low obstacles casting a shadow on the panels and cutting the working time for the panel even further.

The effect of all this is that you will need a far greater claimed panel wattage than your needs seem to require and I would suggest that you probably need between two and three times as many panels as the stated panel wattage would suggest that you need. Considering that chapter 10 shows how to run a generator on water, it would be cheaper to buy and replace a generator on a regular basis than to buy batteries and panels and having to replace them. A generator also runs at night and through the winter.

However, if you are installing solar panels, please be aware that there are considerable differences between panels which have the same apparent rating. A key factor is the voltage produced by the cell under normal working conditions. This makes the difference between a good charging rate under poor conditions and a near-zero charging rate at those times. The good panels have a greater number of cells and the higher voltage produced can make a major difference, so check out the technical specification document on each panel you want to consider and pay attention to the voltage figures and not just the (maximum possible) "wattage" quoted by the manufacturer or sales person. The panels which I picked are made by Kyocera but do your own checking as designs change from year to year. At the present time, solar panels are only about 17% efficient which means that 83% of the power reaching them does not go to make electricity.

Solar panels expand due to heat during the day and so need to be mounted in such a way that allows for this expansion and contraction during the day and night. As you don't want to over-charge a battery, it is generally considered essential to use a control circuit to prevent this happening. In real life, when you use the electricity generated on a daily basis, there is little or no chance of over-charging, but you can decide this for yourself.

One recent development is to use the solar panel(s) to drive a battery-pulsing charging system. This has the major advantage that battery charging does not stop when the light falling on the panel produces a voltage which is too low to charge the battery bank directly. With a pulsing unit, the charging pulse voltage is largely independent of the input voltage and so a good charging rate can be produced in poor lighting conditions, including twilight. This can extend the battery charging period very substantially, especially in winter when there is less light. At this time, one of John Bedini’s companies is offering these units for sale.

Assessing solar panels generally from the standpoint of knowing what the snags are, unless you live in a very good location on the planet and have a good deal of spare money to spend, then they are not a great solution, but this is something which you also need to decide for yourself.

However, having said that, a scheme has recently been introduced in the UK and it appears to be a realistic option. Under this scheme, the householder does not buy the solar panels but merely pays to cover the cost of installing them. For example, this house:

has twenty-one panels mounted on the roof and the total cost to the home owner was just £500. The home owner receives a very much reduced electricity cost and expects to recover the installation cost within two years. Even in November at latitude 52 degrees North, these panels are performing well. No batteries are involved and the panels tie in directly to the electricity grid.

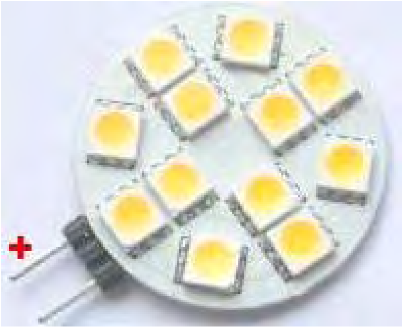
Not having to pay for the purchase of the panels themselves makes an enormous difference to the viability of such an installation. I understand that the strategy behind this scheme is to increase the presently tiny percentage of electricity in the UK, which is produced from renewable sources, by offering people a scheme which actually makes it worthwhile to have an installation.

A Solar Panel Desk Lamp

Solar panels can be very useful items in spite of their very low efficiency and high cost. When thinking about solar panels people generally imagine a set of many large solar panels mounted on the roof of a house. The cost of doing that is far too great for most people to consider it. However, at this time, there are one billion people in the world who do not have any electricity at all. It appears that a useful electricity feature for them would be electric lighting at night. With the components which have become available recently, providing good lighting at realistic cost is now possible.

Small solar panels offered for sale as “10 watt, 12 volt” capacity can now be bought reasonably cheaply. Made in China, these panels can provide a current of just over half an amp These panels which have an aluminium frame are typically 337 x 205 x 18 mm in size and look like this:

Tests which I have run show that a 1000 lux very realistic level of lighting can be provided with a total of just 1.5 watts of electrical power. The best lighting source that I have found is the “G4” style, LED arrays made in China using the “5050” chip technology. These are cheap and have a very heavily non-linear light output for current draw, which is a fact which we can use to our advantage. These LED arrays come in “white” or “warm white” versions (my preference is the warm white variety) and they look like this:



With a diameter of 30 mm and pins which are easy to connect to, these are very convenient devices which have an excellent lighting angle of 160 degrees and a light output of 165 lumens for a 1.2 watt electrical input.

One of the problems with such a unit is the selection of a suitable battery. Lithium batteries are excellent but the cost of a suitable lithium battery is ten times greater than the cost envisaged for the whole unit, effectively excluding lithium batteries. Lead-acid batteries are far too large, too heavy and too expensive for this application. Surprisingly, what appears to be the best choice is the very popular AA size Nickel-Manganese rechargeable battery which is 50 mm long and 14 mm in diameter:

Ni-MH AA 3000mAh 1.2V
Rechargeable

Rated at up to 3 Amp-Hour capacity, they are very low cost, are lightweight and can be placed in a battery box like this:

The battery box can be adapted to hold seven batteries rather than the intended eight batteries, producing a nine volt battery pack with 1.2V batteries. If three of these battery packs are used with the solar panel, then there is no need for over-charging protection as NiMh batteries can deal with overcharging current if it does not exceed 10% of the battery's milliamp-hour rating, and that simplifies the design very considerably.

However, some of these small NiMh batteries do not live up to the maker's claims and so you need to run a load test on any particular make of battery which you may consider using. For example, here are six different types of these batteries tested in groups of four, with a load of about 50 milliamps at five volts. The same load was used to test each of these batteries:

AA
FUSIOMAX
RECHARGEABLE
800mAh

Fusiomax 800

DIGIMAX
AA2850mAh
HIGH PERFORMANCE

Digimax 2850

AA
DURACELL
RECHARGEABLE

Duracell 2400

AA
NEW
SDNMY
Rechargeable
Ni-MH Batteries
3800

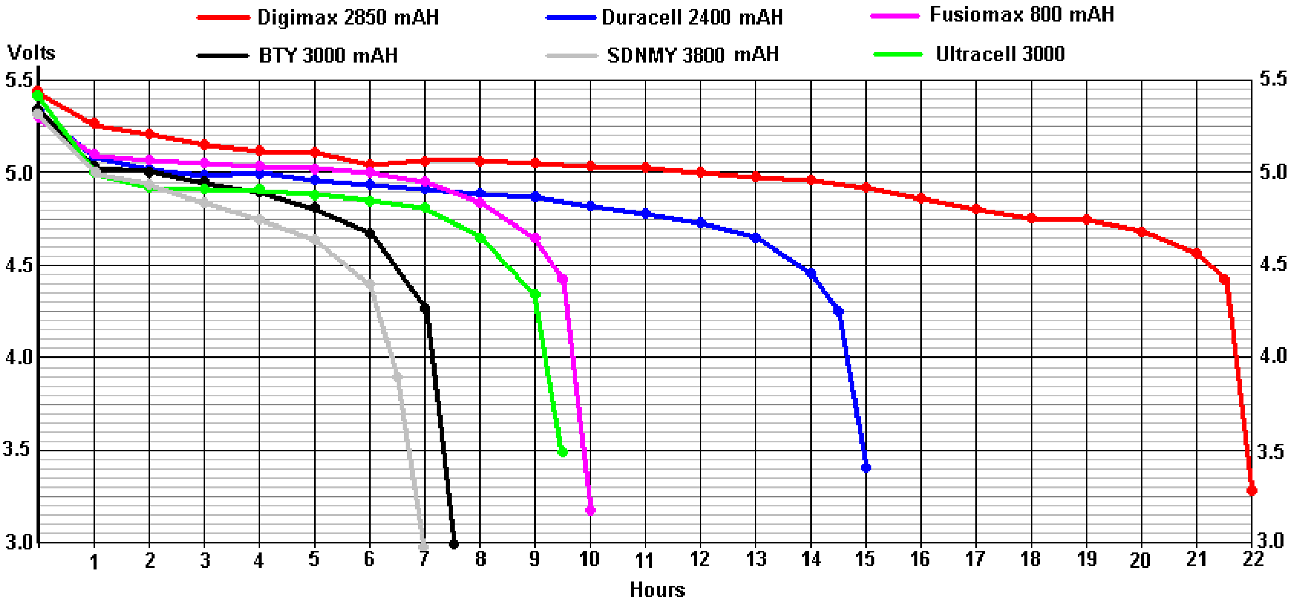
SDNMY 3800

BTY 3000

16pcs
AA 1.2V
3000mAh
3000

Ultracell 3000

The results were most revealing:



The BTY 3000 batteries do not actually claim on the battery to be 3000 mAHr (although the sellers do) and so, the "3000" could just be a trading name. The tests results for the BTY 3000 were so staggeringly poor that the test was repeated three times with longer recharging time for each test, and the one shown above is the 'best' result. You will notice how far short it falls when compared to the low-cost Fusiomax 800 mAHr batteries. The terrible performance of the BTY 3000 batteries is only exceeded by the incredible "SDNMY 3800 mAHr" batteries which show almost negligible capacity in spite of their amazing claims of 3800 mAHr.

NiMh batteries are 66% efficient. You should only ever charge a 3000 milliamp-hour NiMh battery at 300 milliamps or less and so with a 10-watt solar panel, overcharging is not a problem.

Light meter tests provide some very interesting results for the LED arrays. When using two LED arrays side by side in a light box, the figures for voltage / current draw / light produced using 1.2-volt NiMh batteries were:

9 batteries 11.7V 206 mA 1133 lux: 2.41 watts 470 lux per watt (the manufacturer's intended performance)

8 batteries 10.4V 124 mA 725 lux 1.29 watts 562 lux per watt

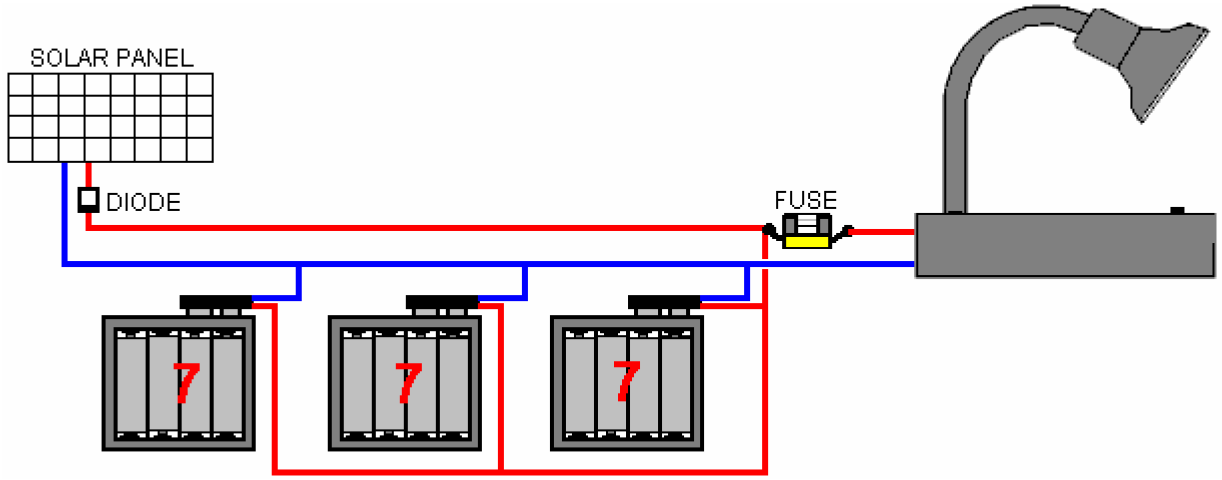
7 batteries 9.1V 66 mA 419 lux 0.60 watts **697** lux per watt (a very realistic performance level)

6 batteries 7.8V 6 mA 43 lux 0.0468 watts 918 lux per watt

This is very revealing information, showing that one of these LED arrays fed with just 33 milliamps can produce very impressive 210 lux lighting at a wide angle of illumination. To put that another way, feeding five LED arrays with 9 volts, generates a very acceptable 1000-lux lighting level for just 165 milliamps which is only 1.5 watts. That is spectacular performance.

Equally impressive is what happens when the battery voltage drops when the battery is nearly fully discharged. The LED performance rises to combat the loss of voltage and even at a ridiculously small 3 milliamps fed into each LED, there is a 21 lux light output from each LED array. The effect is that while the lighting does dim slightly, it does so very gradually in a barely noticeable way. With three sets of genuine high-capacity AA NiMh batteries, we can expect a minimum of eight hours of continuous 1000-lux lighting from our desk lamp. That is a total of twelve watt-hours, and the solar panel feeding 66% efficient batteries at nine volts, is capable of replacing one of those usable watt-hours in twenty minutes. In other words, just two hours forty minutes of good daytime lighting can provide eight hours of 1000-lux lighting every night.

The only moving component in this system is the On/Off switch and the circuit could not be any more simple than this:



All solar panels have a diode to prevent the panel drawing current from the batteries during the hours of darkness and it is not unusual for the panel to be supplied with a diode already connected in place. Personally, I would consider a fuse to be unnecessary but it is standard practice to fit one. The batteries are installed in a base box which supports the solar panel and gives sufficient weight to produce a very stable lamp. The five LED arrays are connected in parallel and fitted into a suitable lamp housing such as this one:

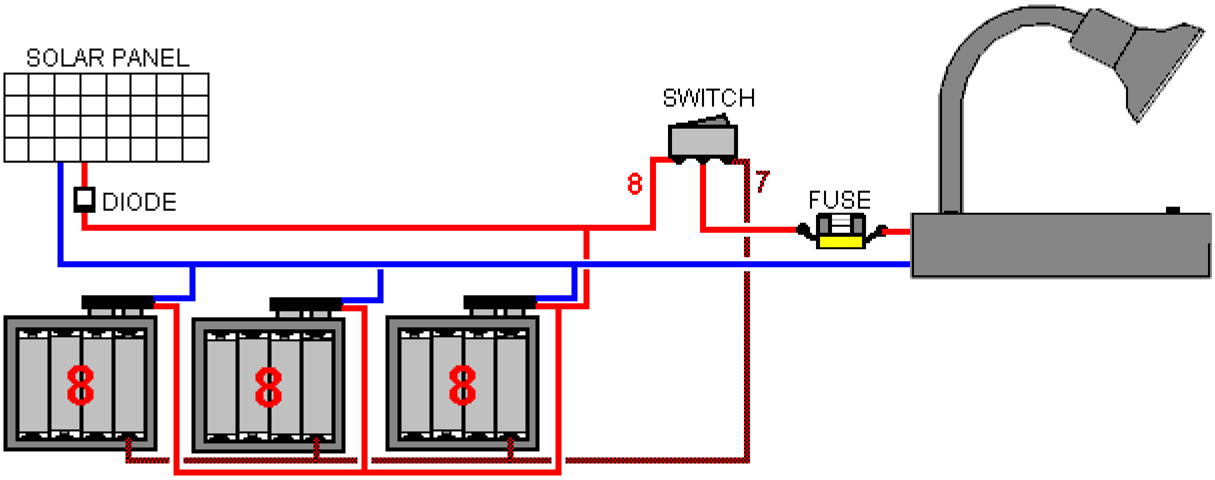
Only the flexible stem, 120 mm diameter lampshade and On/Off switch are used.

While this is an exceptionally simple and robust design, it is actually an affordable and very desirable unit which can provide years of cost-free lighting at a very satisfactory level. The prototype looks like this:

This is, of course, a perfectly ordinary and quite standard type of a solar-powered light. The difference here is that it is a very effective light suited to lighting a desk to a high level all night long. It is mobile and has a wide angle of lighting.

It is also possible to extend the design very slightly, to provide an even longer period of lighting or if preferred, a period of even brighter lighting. This can be done by using eight batteries in each battery holder – which has the advantage that standard battery holders can be used without any need to adapt them to hold just seven batteries.

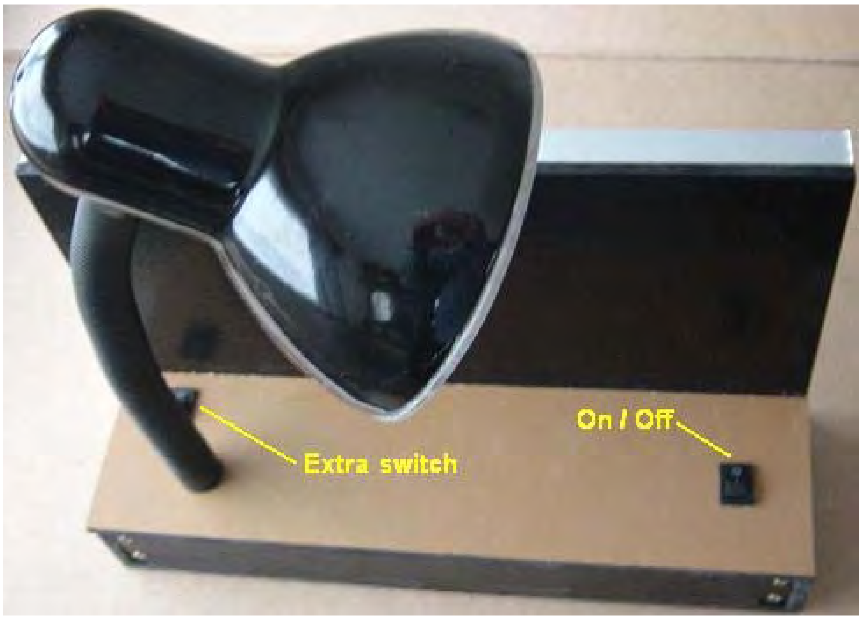
This has the slight disadvantage that we do not want to supply the extra voltage to the LED arrays because doing that would cause a greater current draw than we want. We can overcome this by using an extra change-over switch and having two connections to each battery holder. The circuit could then become:



With this arrangement, the lighting unit is fed by either eight batteries or by seven batteries, depending on the position of the change-over switch. When the solar panel is charging the batteries, all eight batteries per holder get charged no matter what position the extra switch is in.

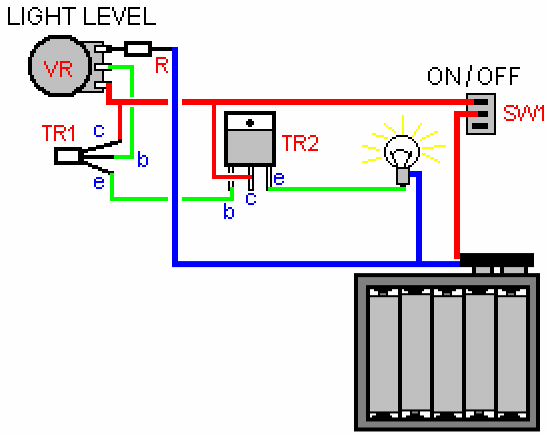
This has the advantage that when the battery voltage starts to drop after a few hours of powering the light, then the switch can be operated, raising the voltage reaching the lamp by the voltage of the extra battery, possibly producing a brightness exceeding the maximum when using just seven batteries in each battery holder. This arrangement has the slight disadvantage that the user could switch in all eight batteries from the beginning, producing a much higher current drain and while that would give a higher lighting level, the overall time is likely to be reduced. Mind you, it is possible that this might suit the user

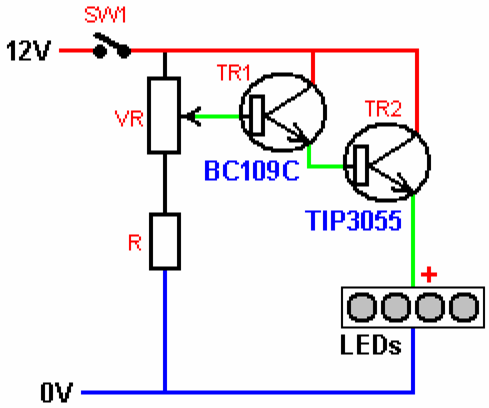
If this style of operation is chosen, then I suggest that the extra switch is located well away from the On/Off switch so that the user does not get confused as to which switch does which job. Perhaps the second switch might be located near the stem of the lamp support, like this:



Without knowing much electronics, it is possible to make a more versatile version of this desk lamp. This can be done by providing a fully adjustable lighting level. For this, we use three 10-battery holders, each containing a full set of ten batteries, producing a nominal 12-volts but in reality, about 13.8 volts when fully charged.

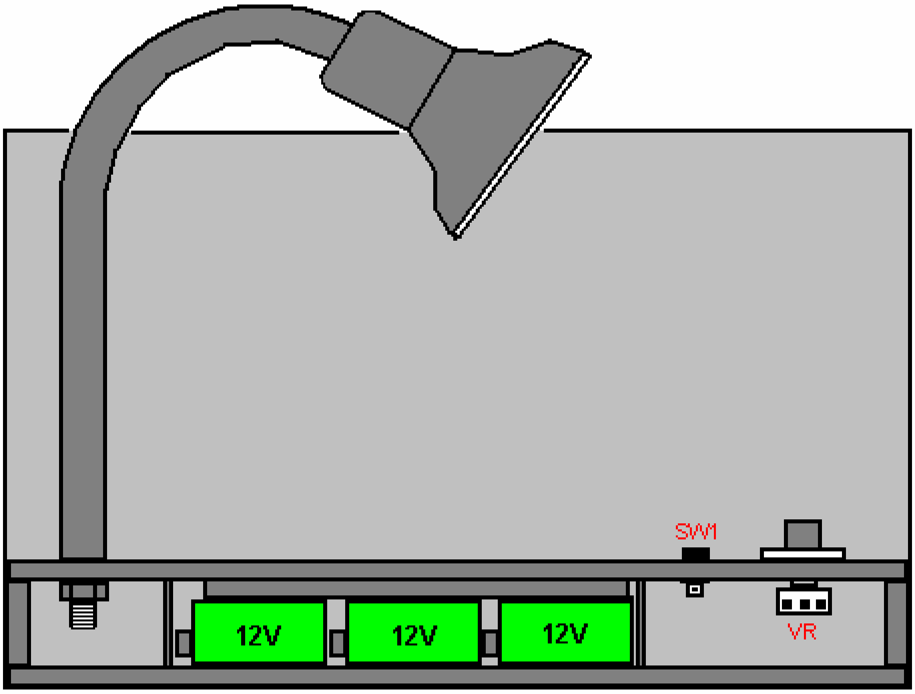
We would like the user to be able to adjust the voltage applied to the LED arrays in order to get the very high current-to-light output efficiency or a higher level for a shorter time, if that style of operation is preferred. This can be done quite easily, in a very simple and cheap way, using this arrangement where just one battery is shown to represent all three battery packs wired in parallel to produce a higher battery capacity:





Here, instead of feeding the battery voltage directly to the LED arrays, two cheap and widely available transistors are placed between the battery and the LEDs. These transistors control the voltage applied to the LEDs and that controls the current through the LEDs and the level of light produced. The chosen light level is set using the variable resistor “VR” and the light level can be turned down gradually, all the way to zero, so the unit could also be used as a night light if that was wanted.

The physical layout of the components could be like this:

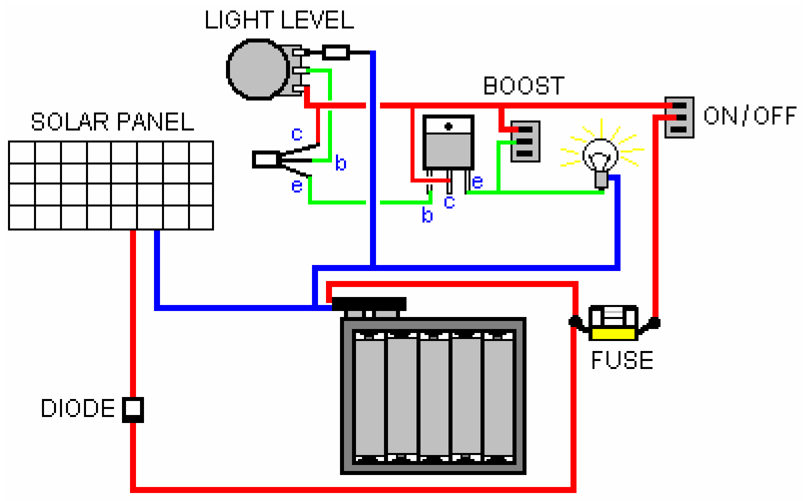


Here, the weight of the solar panel and the three battery packs give the unit stability if the lamp is bent in any direction. With four LED arrays, an excellent level of lighting results, however, I would suggest using five LED arrays as that gives an even wider range of lighting. A big advantage of this arrangement is that if the variable resistor is fitted with a knob like this:

then each user will become familiar with the particular light-level setting which suits the recharging rate. It also allows for short periods of very high level lighting if that ever becomes necessary.

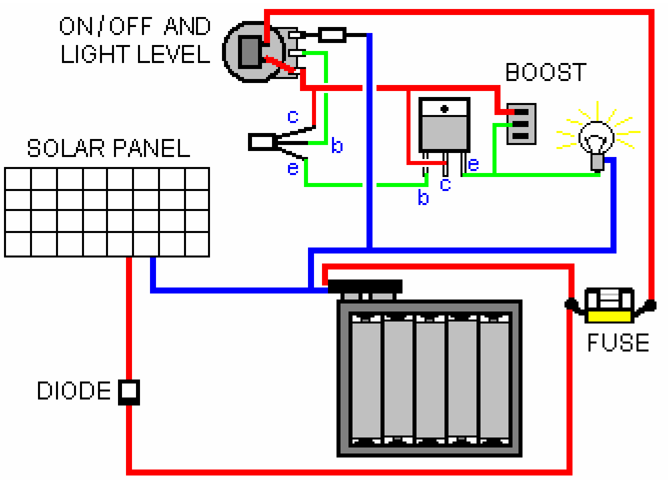
From a practical point of view, when the light is first switched on the battery voltage will almost certainly be over 13 volts. As we want about 9 volts applied to the LED arrays, some four volts need to be dropped off to stop the LEDs drawing excessive current and draining the batteries too quickly. In passing, it might be mentioned that the human eye is very bad at assessing light levels, and so, doubling the LED current (which would more than halve the length of lighting time) does not increase the visual effect by much, and so, controlling the current flow makes a major improvement in the length of time during which the light can be used each night. The lighting period each night is expected to be about eight hours.

The transistors controlling the light level drop off some 1.4 volts, no matter what the current is. This is not a problem during the normal lighting period. However, if the lighting period is unusually long and the battery voltage is starting to drop, then it is possible to gain that extra 1.4 volts by using another switch to bypass the transistor control. It is wired so that the battery is connected directly to the LEDs in order to extract every last milliamp of current from the batteries. That extra 1.4 volts makes a major difference to a falling light level but it should not be used for any length of time on a fully charged battery (quite apart from the excessive current draw) as it is feeding the LEDs a voltage higher than the LED designer was expecting and while it does produce exceptional lighting, it is being very unkind to the LEDs. The bypass switch would be arranged like this:



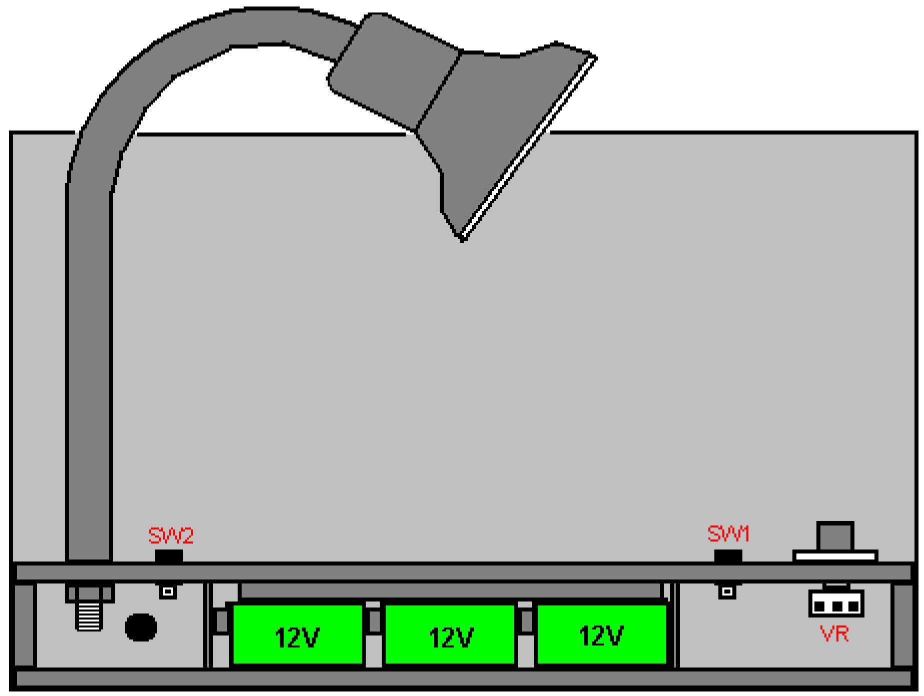
LIGHT LEVEL
BOOST
ON/OFF
SOLAR PANEL
c
b
e
b
c
e
FUSE
DIODE

Here, the extra switch marked “BOOST” short-circuits across the transistors and so connects the LEDs directly to the battery. The fuse shown is optional but if your wiring is not the best, then it is worth having in case your wiring creates a direct short-circuit across the batteries. A ‘slow-blow’ fuse rated at 1-amp would be a good choice as the normal current flow, even on BOOST with a fully charged battery, will be less than one amp if five LED arrays are used. It is also possible to use a variable resistor which has the On/Off switch built into it:



ON/OFF AND
LIGHT LEVEL
BOOST
SOLAR PANEL
c
b
e
b
c
e
FUSE
DIODE

Also shown in the diagram is the solar panel which is connected to the batteries at all times, even bypassing the fuse. It is connected through a diode such as a 1N4007 so that the panel will not draw current from the batteries during the hours of darkness. To make sure that the two switches are not mixed up by the user, I suggest that the extra switch “SW2” is positioned well away from the On/Off switch:

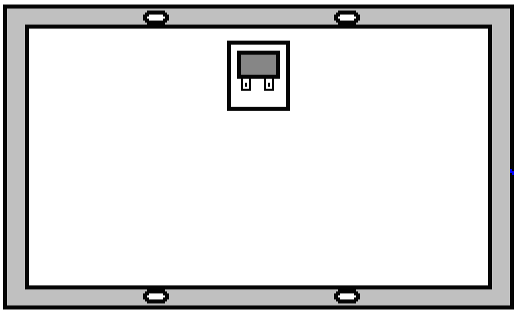


Of course, it is not essential to use a commercial, adjustable lamp such as this. Instead, the LED arrays could be mounted on a home-made strip attached to the back of the solar panel plate and possibly, angled slightly downwards if a desk or table is the main place to be lit. In either case, it is advisable to put a piece of frosted plastic across the LEDs as they can be lit so brightly that they can be difficult to look at. Also, just because this is intended primarily as a desk lamp, there is nothing to stop the user tipping the light upwards to light the whole room. Actually, the room will probably be fairly well lit even when the main lighting area is a desk or table even if that is located at one end of the room.

The construction sequence might be:

1. Lay the solar panel face up on the corner of a sheet of some suitable material such as 6 mm Medium Density Fibreboard ("MDF"). Run a pencil around the edge of the solar panel and cut the sheet along the pencil line to produce a sheet which can be attached to the back of the solar panel. Drill a 6 mm diameter hole about 30 mm in from one corner, that is 30 mm in and 30 mm up so that the hole will be clear of the sides and corner strips when they are attached later on. If it is your intention to paint the desk lamp, then painting this backing sheet before attaching it to the solar panel makes it much easier to do neatly.

2. Lay the solar panel face down on a soft surface and slide the cover off the electrical connection points. It should look like this:

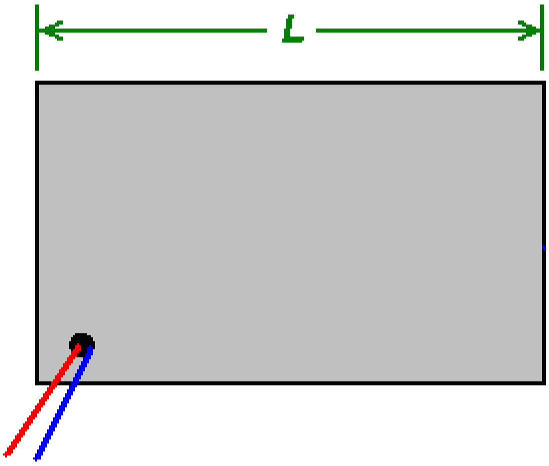


Under the cover, there will be two connection terminals, one marked with a Plus symbol. Some of these panels come with wires already connected and a diode already soldered in place. If there is a diode already there and you are going to remove the cover permanently, it is advisable to embed the diode region in epoxy resin as the diode leads are unduly flexible and could break easily.

If there are not wires already attached, then you need to solder a wire to each of these two terminals. If you do not know how to solder, and don't have a friend who can, then you can learn quite easily. On the web there are several videos showing how to do it. The connecting wire used should not be solid core but should have several tiny strands of wire inside the insulation. The wire should be able to carry at least 1-amp and ideally two or three amps. The thicker the wire, the better electrically but the more difficult it is to solder. The convention is to have a red wire connected to the Plus and a black wire connected to the Minus of the panel, but so long as you know which wire is which, you can use any colour of wire that is convenient. Even if you forget which is which, a voltmeter will tell you which is the Plus when light shines on the panel. These wires need to be about 600 mm. (2 feet) long.

3. Pass the two wires through the hole drilled in the solar panel backing sheet and with the hole positioned at the bottom left. Attach the sheet securely to the back of the solar panel using a good quality adhesive. I prefer to use Impact Evostick or epoxy resin for this, but each constructor will have his own preferred adhesive.

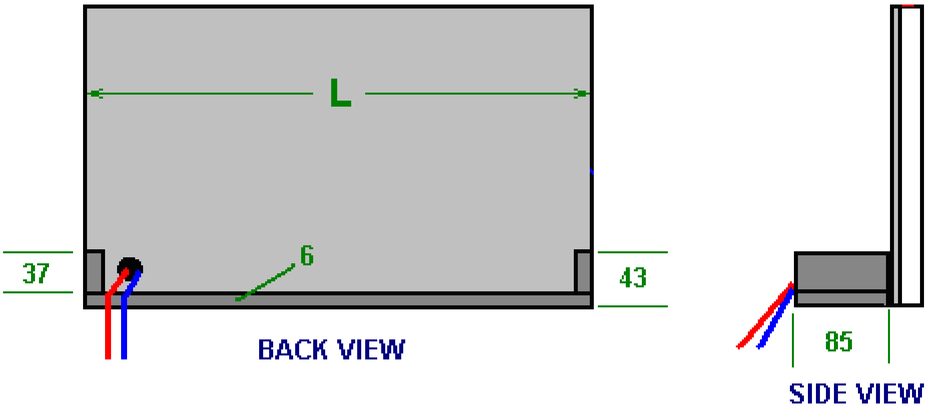
   You don't need the plastic cover which can slide over the terminals and it can be discarded. It is far more important to make good electrical connections to the terminals rather than bothering about keeping under the plastic cover which usually has very, very little clearance and which can get in the way of the backing sheet. The result should look like this:



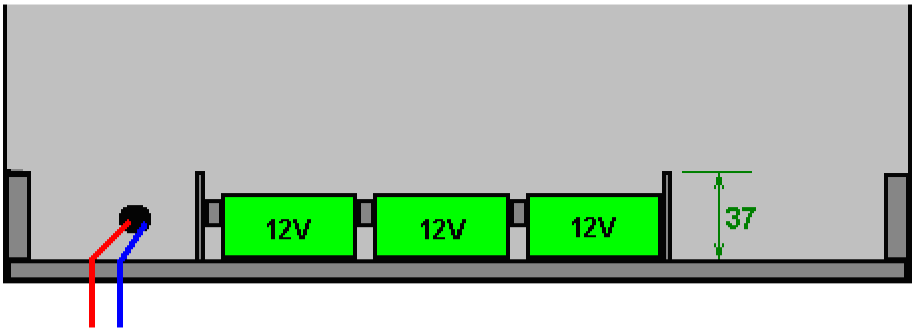
4. We now need to construct the housing for the batteries and other components. For convenience of description, I am going to assume that your sheet material is 6 mm thick. In America, that would be a thickness of one quarter of an inch. Cut a strip of the sheet material "**L**" long ('L' being the length of your particular solar panel). The width of the strip should be width of the battery box (typically 79 mm) plus one thickness of the material, which, with 6 mm thick material is likely to be 85 mm.

5. To make the ends of the box, cut two small strips with a length of that 85 mm (or whatever) and a width of 7 mm greater than the depth of your battery boxes, which are normally 30 mm deep, making the strip typically, 85 mm x 37 mm.

6. Epoxy these three strips to the bottom of the panel backing sheet to form an 85 mm wide, shallow channel like this:

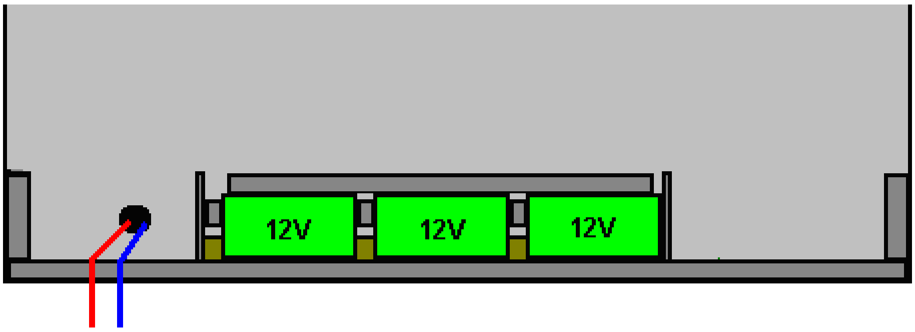


7. Using the same sheet material (or thinner material if convenient), cut two 70 mm x 37 mm strips, and epoxy them one on each side of the three battery boxes. The battery boxes need to have the batteries inserted and the connectors attached to them to ensure that the spacing is right. These dividers connect to the solar panel backing sheet, leaving a gap on the near side as wires have to run from left to right past those dividers. The result should be like this:

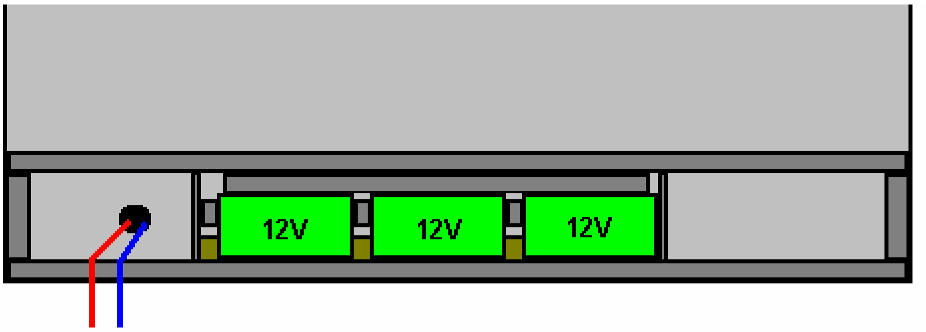


It is important that the batteries are secured so they cannot move at all. As shown above, they can still swivel through an angle due to the gap created by the battery connecting clips. To prevent this, three strips of timber or other suitable material should be attached very firmly to the base to hold the batteries rigidly in place, as shown below.

8. Next, cut a strip of your 6 mm. thick sheet, 65 mm wide and slightly less than the gap between your two dividers. This strip is to hold the batteries securely in place and still allow room for wires to be run past the batteries. The strip will **not** be attached to the solar panel sheet although it will be positioned very close to it. Check that it fits in place. The gap will be on the near side to make the final wiring easier:



9. The next step is to cut the top strip which will hold the lamp, switches and variable resistor. While the lamp fitting is quite light, the length of the arm is so very much greater than the diameter of the screw thread which attaches it to the top plate that any load applied to the lamp arm when adjusting its position, generates many times that stress in the area of locking nut holding it in place. Because of that stress in such a small area, it is suggested that the top plate be particularly strong. A strip of laminate flooring material is very tough and being only 7 mm thick, it is not difficult to work with, so cut a strip to run across between the two end pieces like this:

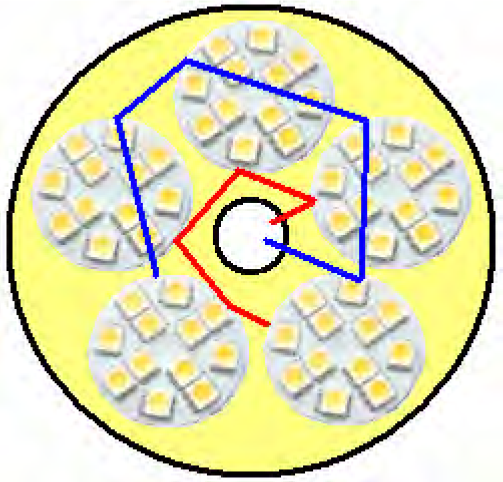


The objective here is to enclose the batteries so that they cannot move, nor can any individual AA cell move out of position. The laminate flooring strip will be used face down as the underside is normally a conservative and attractive matt finish which is particularly suited to this project.

10. It is much easier to work on the laminate strip before it is attached in place, so we will drill the holes for the lamp column and the variable resistor, and cut out the rectangular holes needed for mounting the two rocker switches. In the UK, the rocker switches and variable resistor look like this:

The switches need a rectangular hole of 13 x 19 mm, while the variable resistor needs a 10 mm diameter circular hole and the lamp shown also needs a 10 mm diameter hole. Hold the laminate strip in place and mark the locations carefully, making sure that each item will not foul anything underneath before cutting out the various apertures. Slide the knob on to the shaft of the variable resistor and note the length of shaft inside the knob. Cut the shaft, leaving that same length of shaft remaining. Attach the variable resistor and switches to the laminate strip and slide the knob on to the remaining variable resistor shaft. The skirt of the knob should now be close to the surface of the laminate strip and a V-shaped piece of material can be glued in place to give a reading point for the scale on the knob.

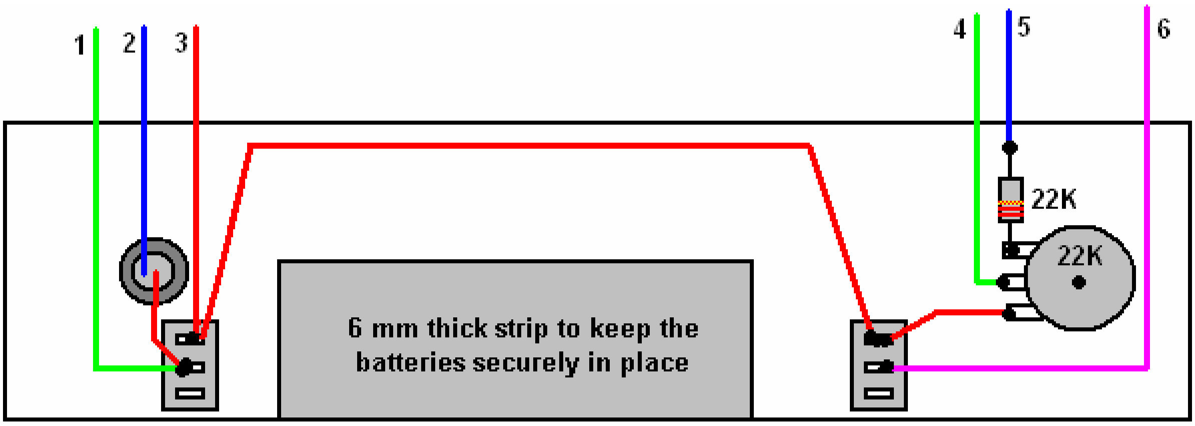
11. If a commercial lamp is being used, then it needs to be taken apart now and prepared for this project. The base is removed, the bulb holder is removed and two wires are fed through the remaining shaft so that the LED arrays can be fitted. A circular disc of any kind of rigid material is cut, the diameter being slightly less than the diameter of the mouth of the lamp. Four or five LED arrays (depending on your choice of numbers) are glued to the disc and wired up in parallel with all of the plus wires connected together and to one of the wires feeding through the shaft of the lamp, and all of the minus wires connected together and attached to the other wire passing through the column of the lamp:



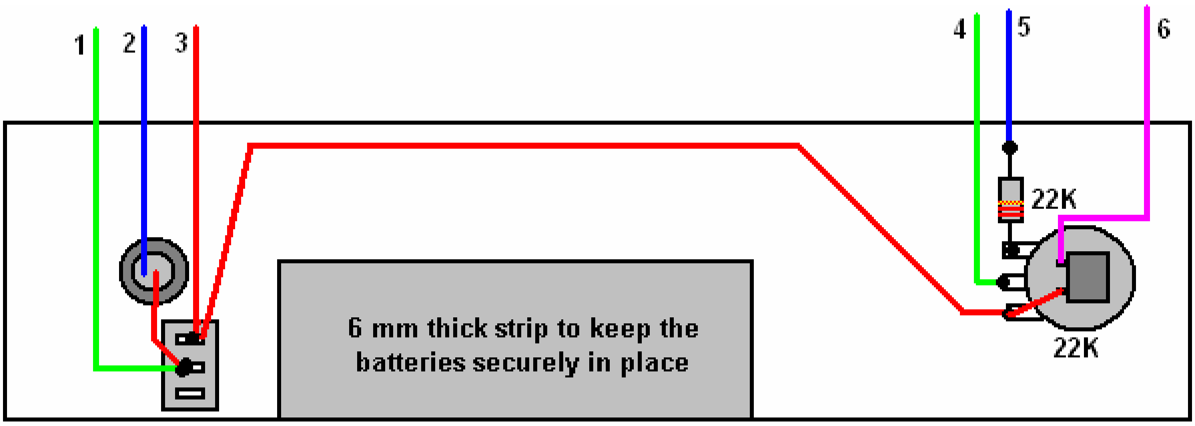
This disc is then eased through the mouth of the lamp shade where it sits about 10 mm below the rim of the shade due to the taper of the shade. Position the disc so that it is square on to the rim of the shade and glue it in position. If frosted plastic is to be used, then mark the sheet around the rim of the shade and cut out the resulting circle, drill some ventilation holes in it although the LED arrays always run cold, and glue the frosted plastic disc to the rim of the shade.

12. Connect the wires to the switches and variable resistor mounted on the laminate strip, and then position the lamp in its hole and fix it in place by tightening one nut. There are two nuts but I have found the locking nut to be less than adequate, so epoxy the tightened nut to the remainder of the screw thread as that keeps the nut securely in place and yet allows the lamp to be rotated quite easily.

To make construction easier, before placing this laminate strip in place, if a separate On/Off switch is being used, then make the connections shown here:

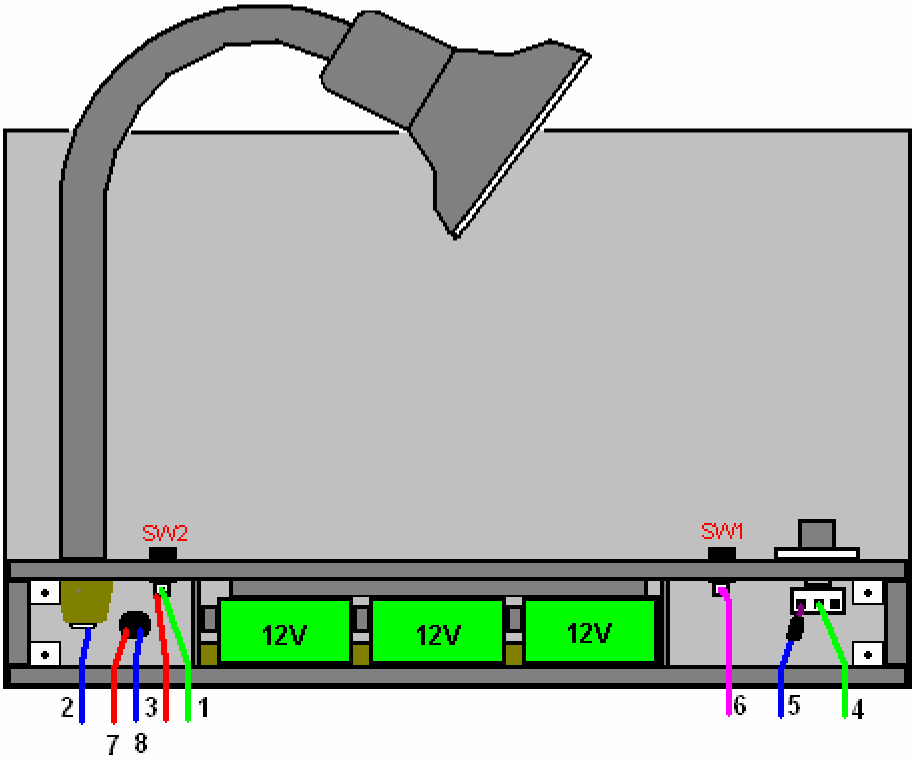


If a variable resistor with an integral On/Off switch is being used, the these connections become:



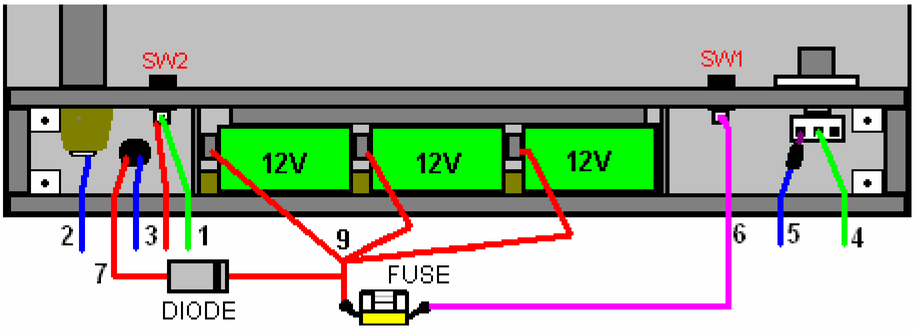
The 22K fixed resistor (colour bands red/red/orange) is connected to one of the outer tags of the 22K variable resistor and wire "5" is connected to the other end. I suggest that all wires coming off this panel are at least 200 mm (8-inches) long. A separate wire "4" is connected to the centre tag of the variable resistor, and the third tag is connected to the On/Off switch as shown, and when making the connection to the switch, also connect another wires to that same tag. The extra wire is run across and connected to the top tag of the "boost" switch along with another wire "3". The wire connecting the switches is run close to the outer edge of the laminate strip so that it will clear the battery packs, as there is very little clearance past the batteries in order to hold them tightly and prevent them moving. The negative wire of the LED arrays is connected to the centre tag of the "boost" switch and another wire "1" is taken out from that central tag. When connected up as shown, there will be six wires coming out from the laminate strip and I will refer to these wires by the numbers shown above, so it might be worthwhile actually tagging those wires temporarily with those numbers.

13. If inclined, apply some glue to the variable resistor and switches (on the underside of the laminate strip) but do **not** epoxy the strip in place until the final connections have been made and the circuit confirmed to be working, including the solar panel charging the batteries.

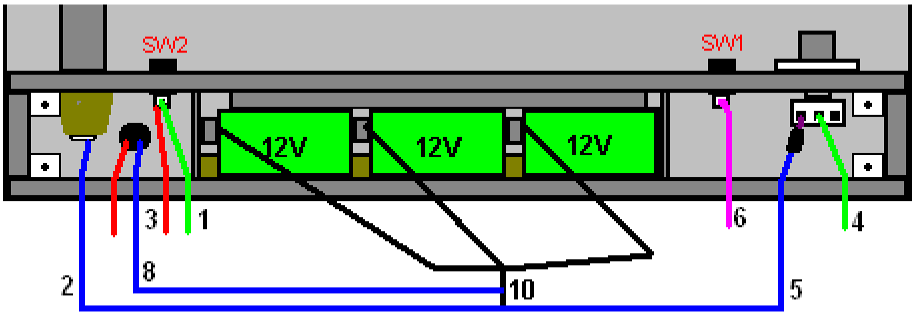


14. The final connections which need to be made are:

a. The non-striped end of the diode is connected to the Plus wire “**7**” coming from the solar panel and the Plus wire of the three sets of batteries are connected together “**9**” along with the striped end of the diode and one end of the fuse (if no fuse is being used, then wire “**6**” is connected directly instead of to the other end of the fuse). A fuse rated at 1-amp would be suitable as the working current should only be one sixth of that:

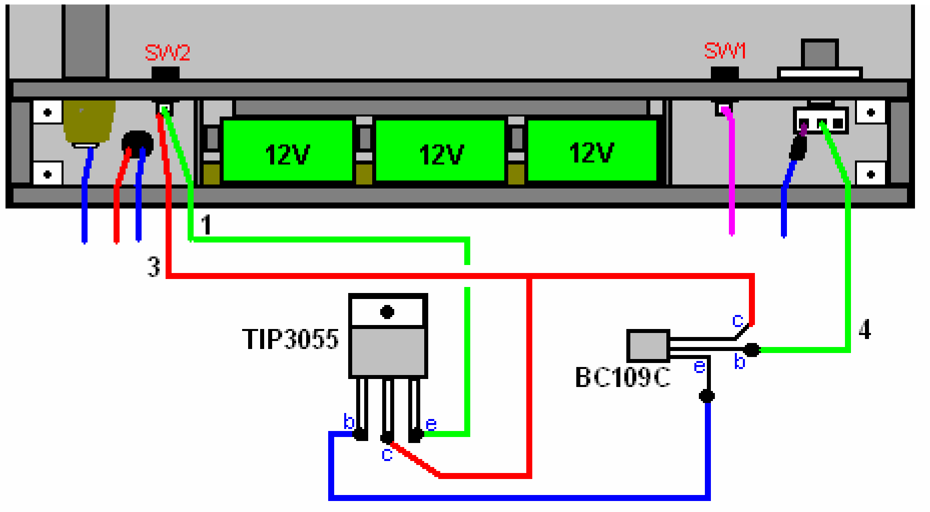


b. Remove the insulation from the Minus wires coming from all three battery packs and twist them together (“**10**”). Connect wires “**2**”, “**5**” and “**8**” to this collection of Minus wires and solder them together make a solid joint, and insulate the joint with duct tape, epoxy, or any other robust form of insulation:



SW2
SW1
12V
12V
12V
3
1
6
4
2
8
10
5

c. To complete the wiring, the three remaining wires are connected to the two transistors like this:



SW2

Emitter
BC109
Emitter
Base
Collector

Please be aware that transistors are heat sensitive and so soldering transistor leads needs to be completed quickly and where possible, the transistor lead held in a pair of pliers while the solder joint is being made and when it remains hot, as the pliers diverts the heat away from the transistor.

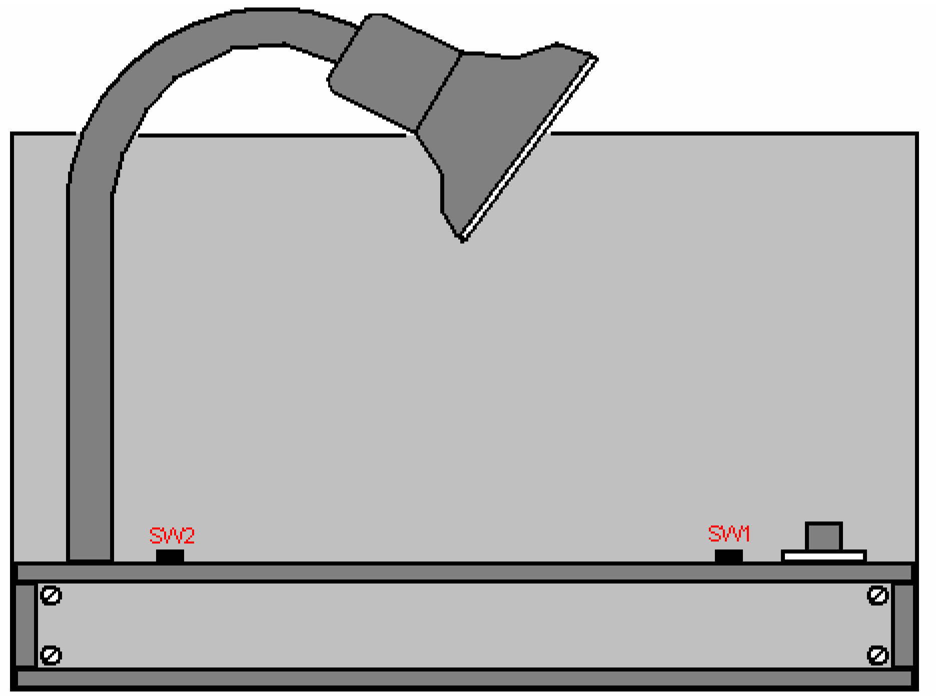
The desk lamp is now ready to be tested.

15. If the light goes on and off when the On/Off switch is operated and the light intensity alters when the variable resistor knob is turned, and if the light level increases when the “boost” switch is closed, then all is well and the laminate strip can be epoxied into its final position. If the desk lamp does not operate as it should, then follow the test procedures below, until the desk lamp is fully functional and then continue with step 16.

16. Epoxy the laminate strip in position and glue four short lengths of timber in the corners. These lengths of timber should reinforce the joint between the four pieces which form the housing and the solar panel backing sheet, and they should stop off 6 mm short of the outside edge so that they both support the final piece as well as holding it in place.

17. Connect a voltmeter across the LEDs and rotate the knob of the variable resistor to get 9V across the LEDs and note or mark the reading on the scale attached to the knob. This is the initial setting for the knob when starting with a fully charged battery.

18. Finally, insulate the transistor circuitry with tape, plastic or whatever method suits you and secure it in place with a little adhesive to make sure that the wiring does not break if the unit is moved a lot. Then, a strip is cut to close the box and screwed at the corners using woodscrews or bolts:



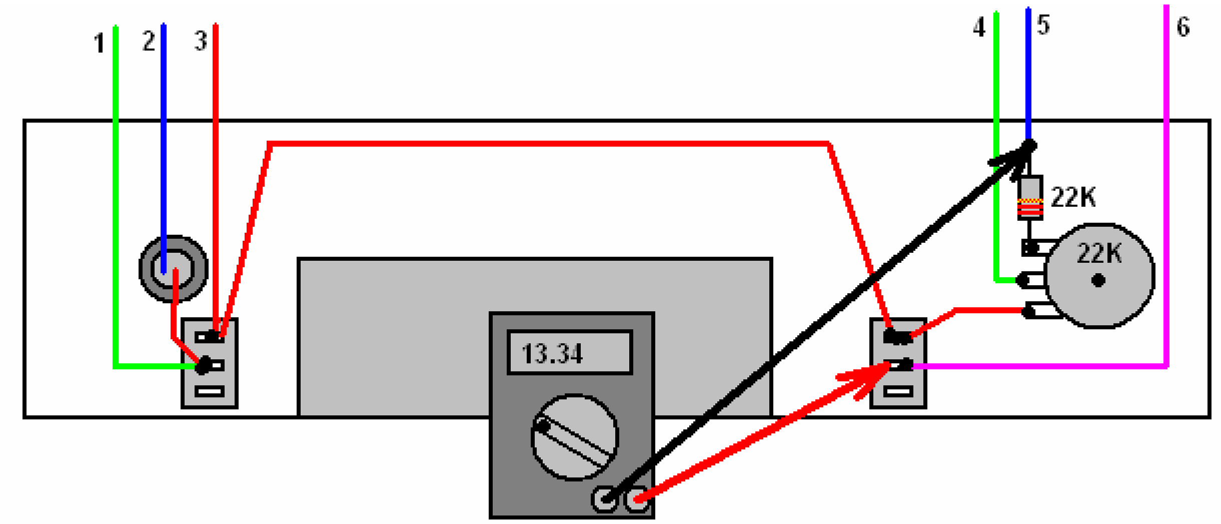
The gap between the two rocker switches provides an easy gripping point for carrying the unit from place to place.

While this solar desk lamp can be built this way at quite reasonable cost even with one-off prices on individual prices, a really major improvement is achieved if they are being manufactured, especially if made in China. Firstly, all the effort of making the housing disappears as a cheap custom plastic case does away with all that time and effort as the solar panel has its wires connected, fed through the existing hole in the case and then the panel is just pushed into place. The battery packs are then assembled and pushed into place, the circuit connections made and the case clicked closed on its own or held in place by self-tapping screws. The component prices drop enormously with bulk purchasing, reducing the not unreasonable one-off price by a major factor, especially since wages in China are very low by our standards. The result is an attractive, useful product with a very large market and a unit price capable of taking full advantage of that large sales base.

Test procedures:

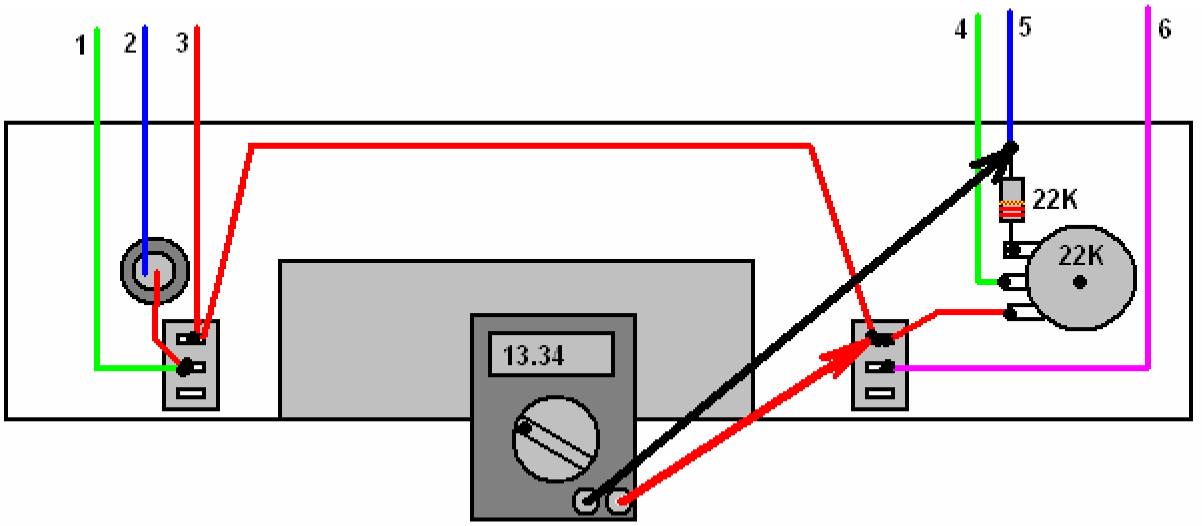
If the unit does not work straight off, then step-by-step tests are needed to locate and fix the problem. These are simple, common sense tests. If you do not have a voltmeter, then it is worth purchasing one as they are now very cheap.

1. We need to confirm that the battery has the electrical power to run the lamp, so open the “boost” switch “SW2” and connect a voltmeter as shown here:



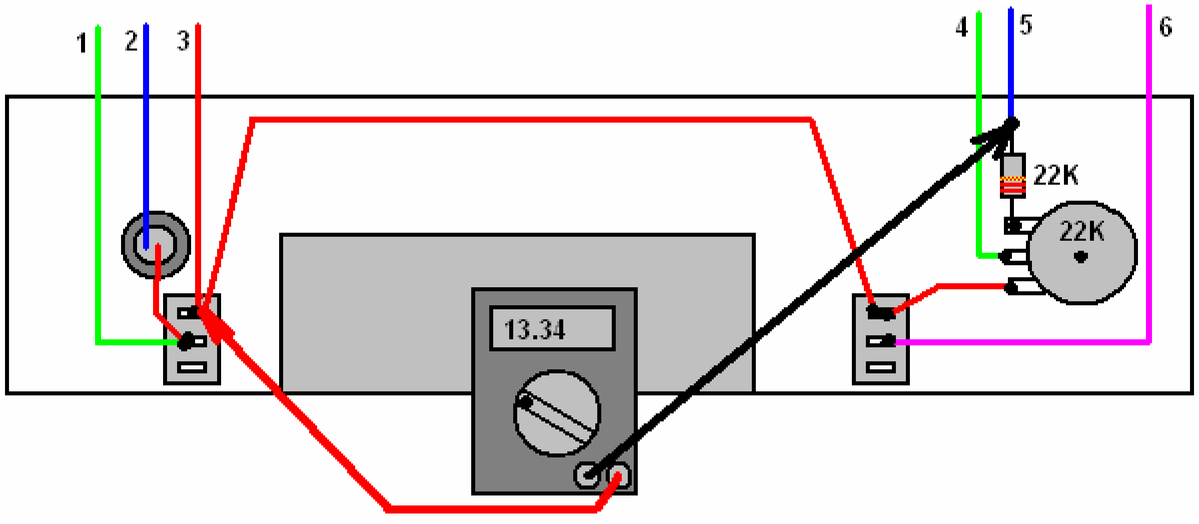
This connects the meter directly across the battery and so the meter should show some realistic voltage around the 12V mark. If it doesn't, then lift out one of the battery holders and check that the batteries are charged and confirm that the fuse has not blown. If the fuse has blown, then it will because of excessive current, probably caused by a direct short-circuit where the battery Plus is being connected directly to the battery Minus. Check the wiring from the battery to these two points until you do get a sensible voltage reading.

2. Next, connect the meter like this:



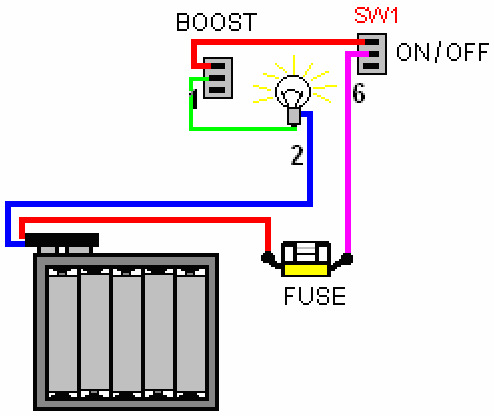
and confirm that the voltage appears and disappears when you operate the On/Off switch. If it does not, then it is highly likely that your connections to the two switch tags are touching and stopping the circuit being switched off. If that is the case, then adjust one of the connections to cure the problem and leave the On/Off switch switched On.

3. The next step is to connect the meter like this:



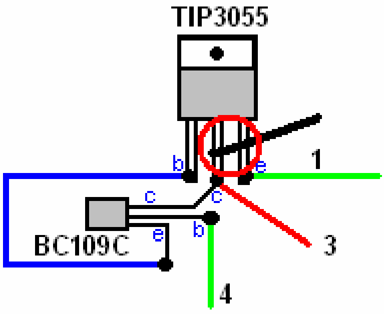
The same voltage reading should be seen. If it isn't, then the wiring between the two switches is almost certainly defective and needs to be corrected.

4. Now close the boost switch, and the light should come on at full intensity because the transistors are being bypassed and the battery connected directly across the LEDs. The circuit is then:



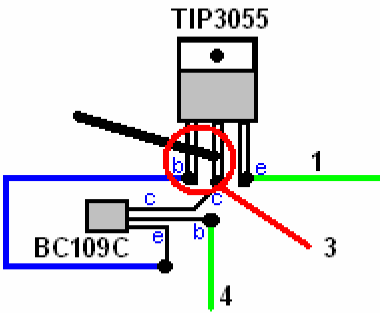
If the light does not come on brightly, then check the wiring around this path – battery Plus – fuse – wire "**6**" - On/Off switch – boost switch – wire "**1**" – LEDs Positive – LEDs Negative – battery Minus (wire "**2**").

5. When the boost switch circuit is working correctly, turn the boost switch off and check the operation of the transistors. First, use a screwdriver to short-circuit between the Collector and Emitter of the TIP3055 transistor:



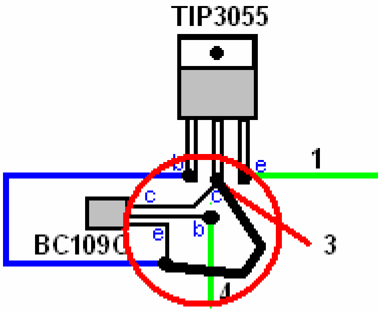
This should have exactly the same effect as closing the boost switch but it is testing your wiring connections to the power transistor and simulating the TIP3055 being switched on fully. If this does not produce the full light output, then you need to check (visually) the wire "1" connection between the centre tag of the boost switch and the Emitter of the TIP3055 transistor. Also check the connection between the Collector of the TIP3055 transistor and the top tab of the boost switch as one or both of those connections has to be faulty if the boost switch works when you switch it On.

6. When you have corrected the wiring and short-circuiting between the TIP3055 Collector and Emitter turns the light on at full brightness and the light-level control variable resistor is still not controlling the light level, then short-circuit between the TIP3055 Collector and Base:



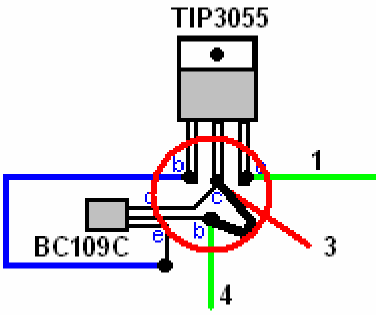
This bypasses the BC109C transistor and should produce the maximum light level. If it does not, then the TIP3055 transistor is defective. This is highly unlikely as the TIP3055 is enormously robust and can survive all sorts of mishandling. However, if this test definitely fails, replace the transistor without connecting its Base and confirm that the new one switches the light on fully when you short-circuit the Base to the Collector. Then connect the BC109C and repeat the TIP3055 Base to Collector short-circuit test to confirm that it is still working with the BC109C in place.

7. If the light-level control still does not work, then short-circuit the BC109C transistor's Emitter to its Collector:



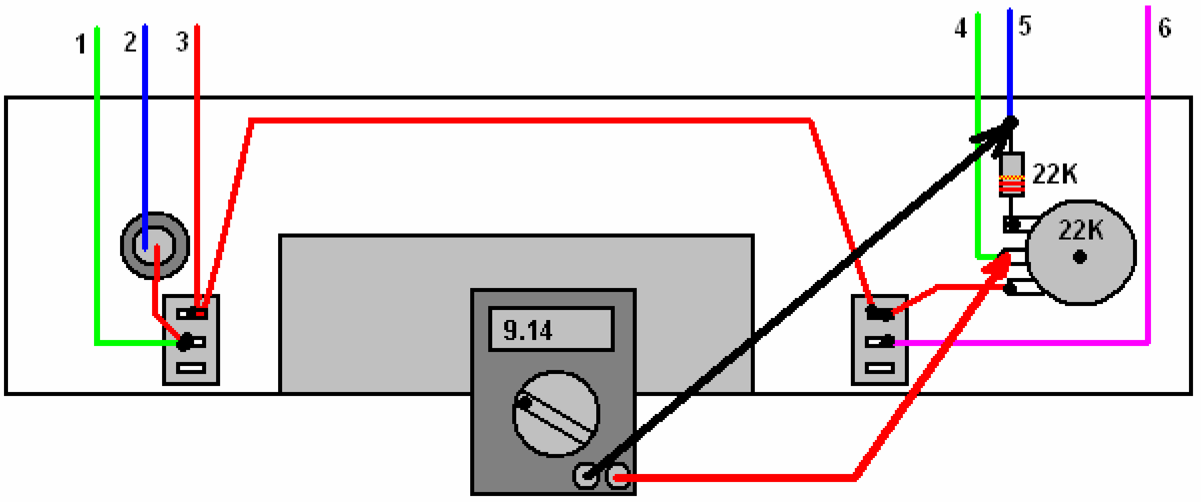
This checks the wiring between the Emitter of the BC109C and the Base of the TIP3055 (shown in blue in the diagram above). If the light comes on at full brightness, then the wiring is okay, otherwise, correct that connection.

8. Now we test the operation of the BC109C transistor. Turn the light-level control knob down to its minimum and short-circuit the BC109C Base to its Collector:

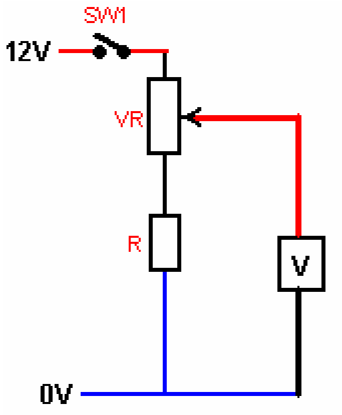


With the short-circuit in place, the light should be fully on and with the short-circuit removed (or if its base is short-circuited to its Emitter), the light should be fully off. If this does not happen, replace the BC109C transistor and repeat the test.

9. If the light-dimming control still does not control the light level, then the wiring of the variable resistor has to be suspect, so connect your voltmeter like this:



This is making a connection between the negative line and the slider of the variable resistor, and that should allow the slider to adjust the voltage fed to the BC109C transistor:



This is the test and unless there is a major problem with the resistor “R”, the variable resistor “VR” or the transistors short-circuiting the slider of the variable resistor, your voltmeter should show your full battery voltage when turned up as high as possible, and an evenly falling voltage to around half that voltage at the other end of the variable resistor shaft movement.

If this does not happen, then you need to check over the wiring connections for the variable resistor, fixed resistor and connection to the base of the BC109C transistor.

Components for home-build:

1. One 10-watt, 12-volt solar panel.
2. Thirty AA-size, 1.2V NiMh batteries with a capacity near 3000 mAHr if possible.
3. Three AA battery boxes each holding 10 batteries.
4. Three battery clip connectors to fit the battery boxes.
5. One 1-amp diode type 1N4007 or similar.
6. One 22K Linear variable resistor and graduated knob to fit the shaft diameter.
7. One 10% quarter watt (or higher rated) 22K resistor (colour bands red/red/orange)
8. One BC109C transistor.
9. One TIP3055 transistor.
10. Five G4 LED arrays.
11. One desk lamp (optional)
12. Two rocker switches.
13. One fuse holder (of any type) and a 1-amp fuse.

14. Ten metres of insulated, stranded wire rated for 1-amp or higher current.
15. Rigid sheet material 6 mm thick (possibly MDF).
16. One small off-cut of laminate flooring 85 x ***L*** (typically 337) mm
17. Adhesive.
18. Rubber feet or soft material for the underside of the desk lamp.

Notes:

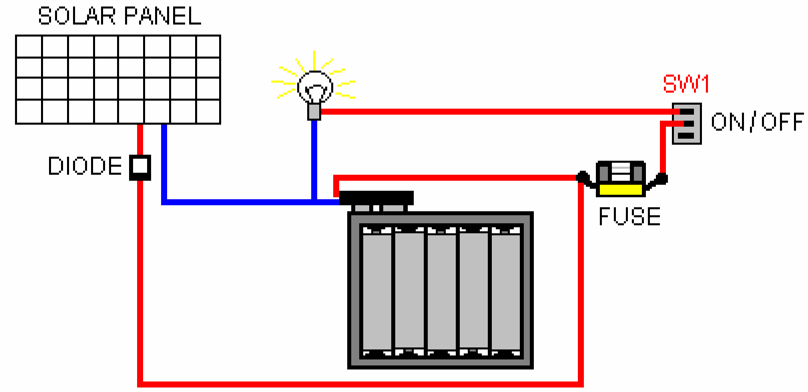
Rocker switches are generally cheaper as the Change-over version with three switch tags, and so these have been shown. For this design, only On/Off action is needed. Press the "1" end of the rocker down, and the two contacts used are then the two farthest away from the "1".

The TIP3055 transistor is the more recent version of the 2N3055 and is a particularly good transistor for this application being much easier to connect to. While the TIP3055 is strongly recommended, other power transistors may be used. No heat sink is needed if the transistor can handle 8 amps or more (the TIP3055 can handle 15 amps and 90 watts).

The BC109C transistor has a very high gain between 200 and 800, which is useful in this application, but a major advantage of it is that it switches off fully with pretty much zero leakage current, while I have some of the very popular 2N2222 transistors which don't switch off properly at all and so are effectively rejects. Most alternative transistors are highly inferior to the BC109C and so, if it is not readily available, then it is worth ordering.

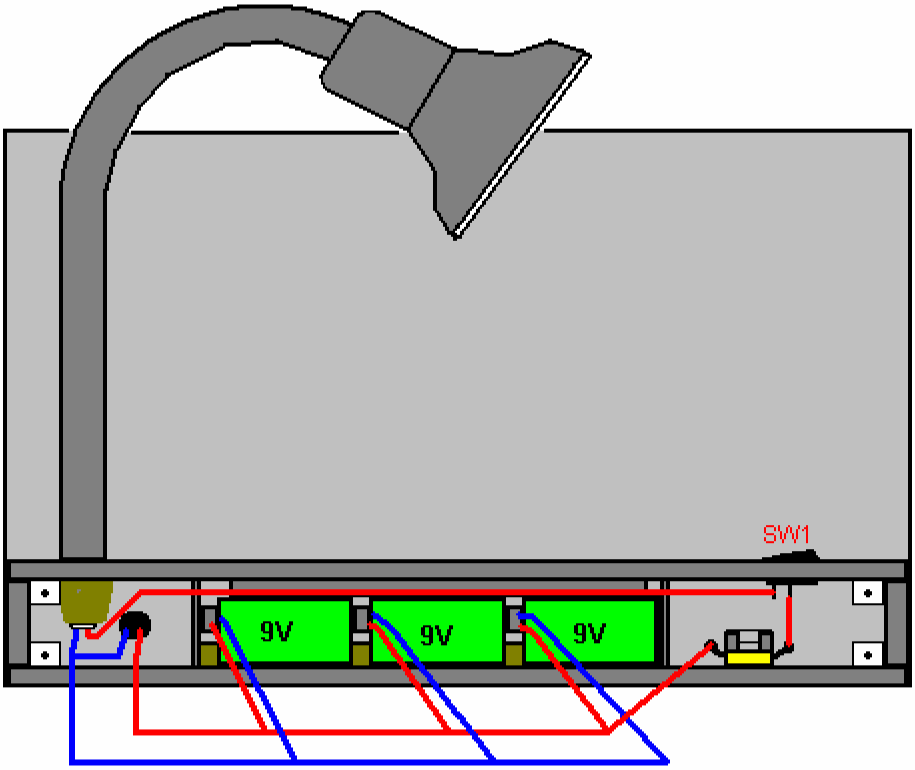
The 1N4007 diode is the cheapest readily available diode. It is rated for 1000-volt operation which is of course, of no interest here and so the lower voltage 1N4001 through 1N4006 diodes are perfectly suitable although slightly more expensive as they are less popular. While one diode is shown in this document, people who are expert in electronics are inclined to use three connected in parallel as that passes current more freely. That would cost an extra 6 pence at 1-off prices in the UK.

Some people are really put off by electronics of any kind, so here is a version of the solar desk lamp which effectively, has no electronics at all:

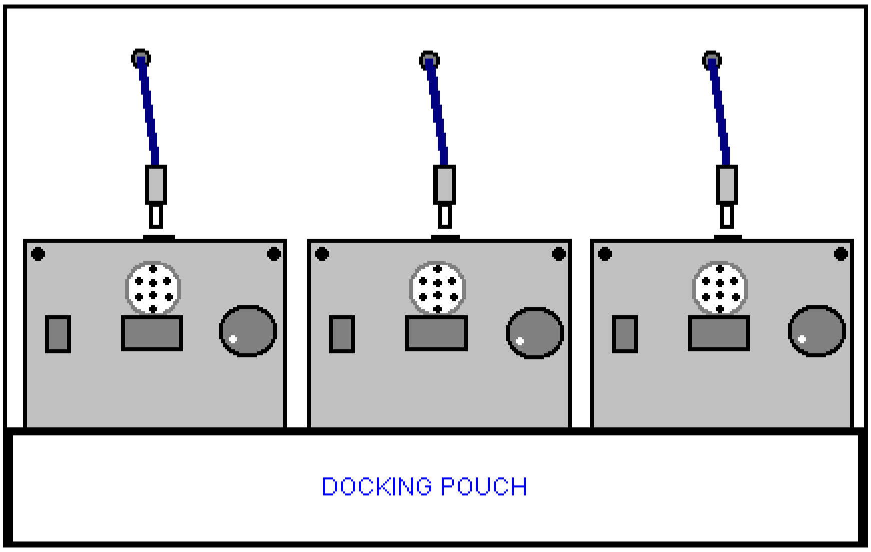


The only control on this version is the On/Off switch. As we no longer have any control over the voltage applied to the LED arrays installed in the lamp shade, and since that voltage controls dramatic changes in current draw, we need to reduce the number of 1.2V NiMh batteries from ten to seven. It is a matter of choice whether you use three or four sets of seven batteries. If 10-battery battery boxes are used, then a wire can be soldered across the gap left by the three omitted batteries.

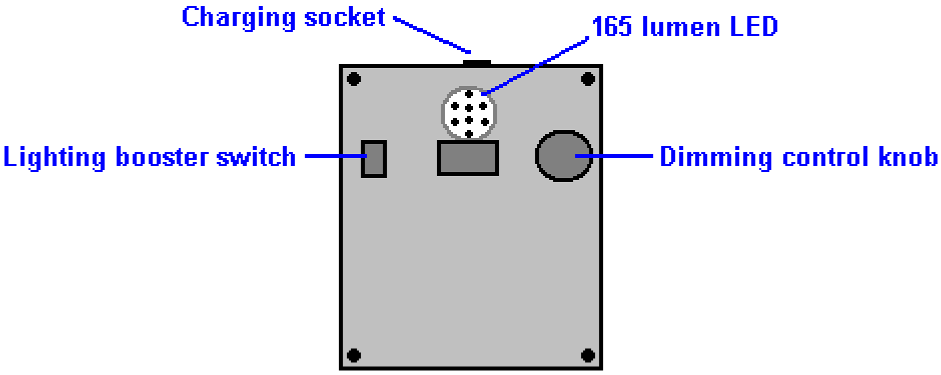
The general construction is the same as before, with a rocker On/Off switch being installed instead of the variable resistor. As with all of these solar units, the important thing is to switch the light off when it is not in use, to avoid the next charging session being hindered by unwanted current draw through the light. The general layout of the unit can be the same:



There are other variations which can be low-cost and very versatile. For example, instead of connecting the three battery packs together, they can be kept separate from each other, individually housed with the same circuit, each driving one of the LED arrays:

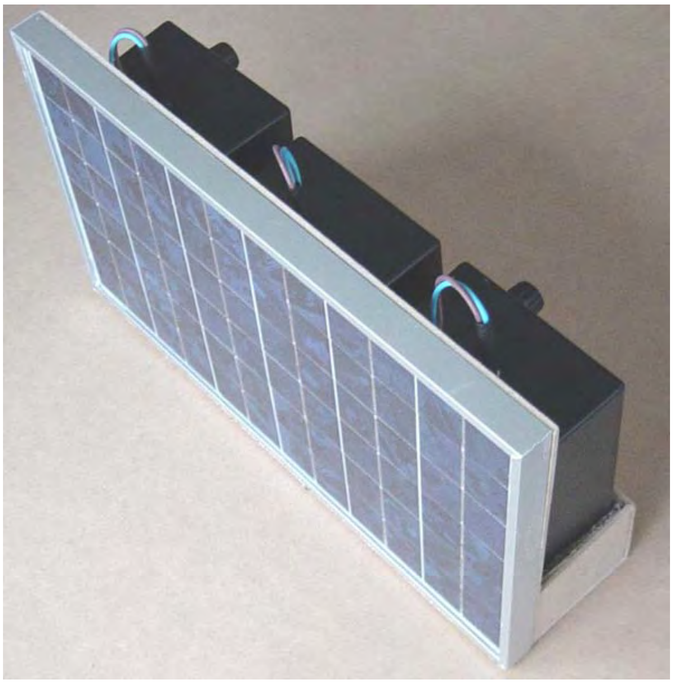


Here, three identical units are charged from the solar panel, which can be any size or wattage, although a ten-watt panel would be considered to be the minimum for daily use. Each unit is in effect, just a wide-beam, high-intensity, high-capacity solar torch which can be dimmed and which will stand securely when unsupported. It has the advantage that the units can be constructed one at a time, and if necessary due to time constraints, or perhaps, very poor daylight, just two or even one unit can be charged from the entire solar panel output. If manufactured and sold, then the units could be sold separately, allowing a lighting system to be extended and improved when additional funds become available (or when the user has tried one unit and discovered how effective it is). Each unit is easy to understand and use:



Charging socket
165 lumen LED
Lighting booster switch
Dimming control knob

A built unit of this type looks like this from the front:

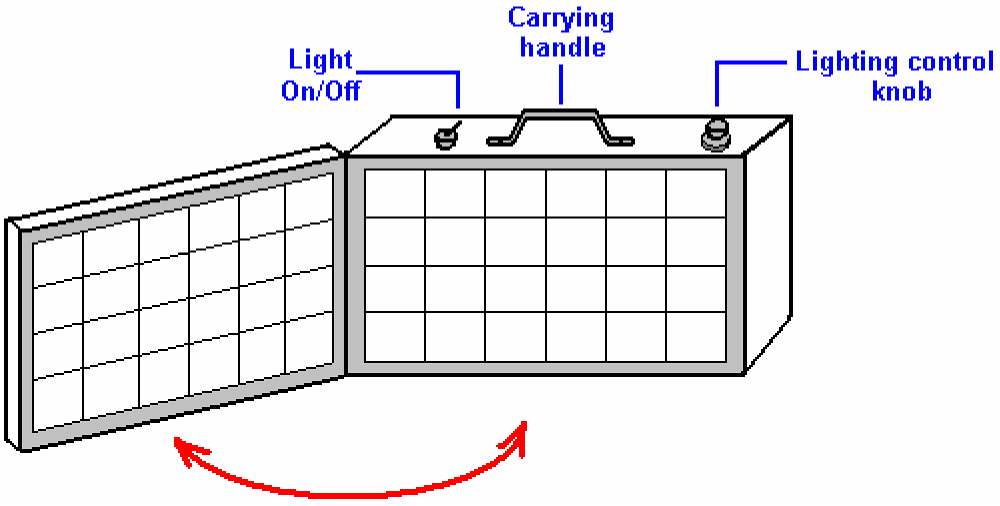


and like this from the back:

While these particular units have just one of the LED arrays each, tests run since that construction show that with manual dimming control, two LED arrays per unit would be more satisfactory. Also, if the second LED array is mounted on the side of the box, then the lighting angle increases from 160 degrees to 250 degrees which should be helpful for indoor lighting of a room. The units could, of course, be used in different rooms simultaneously and there is the option of carrying one around for lighting anywhere. Again, the construction is very simple and the same circuit as for the desk lamp shown above, can be used in each box.

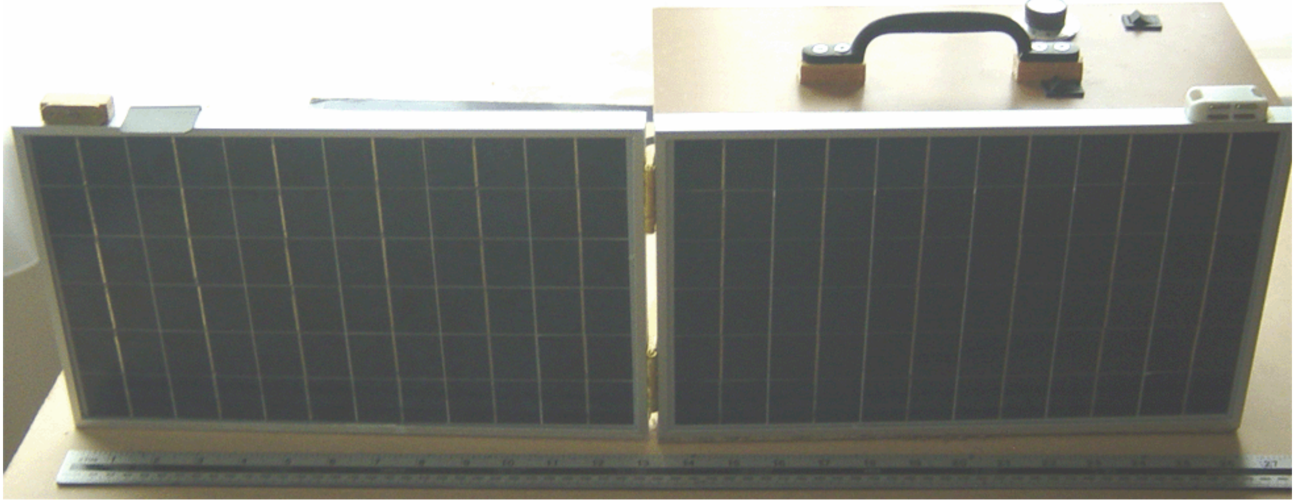
If good-quality NiMh AA-size batteries are used, each of the mobile units is capable of providing good light for eight hours, which means that if it gets dark at 4 pm (16:00), lighting is available until midnight as a minimum, at which point in time, the user should be going to sleep.

If a very powerful single source of lighting is needed, it is possible to use a larger solar panel, or for a more compact unit, two of the 12-volt 10-watt panels shown above. The arrangement can use the same simple manual control of lighting level and the same booster switch for even greater lighting for a few minutes. The arrangement can be like this:



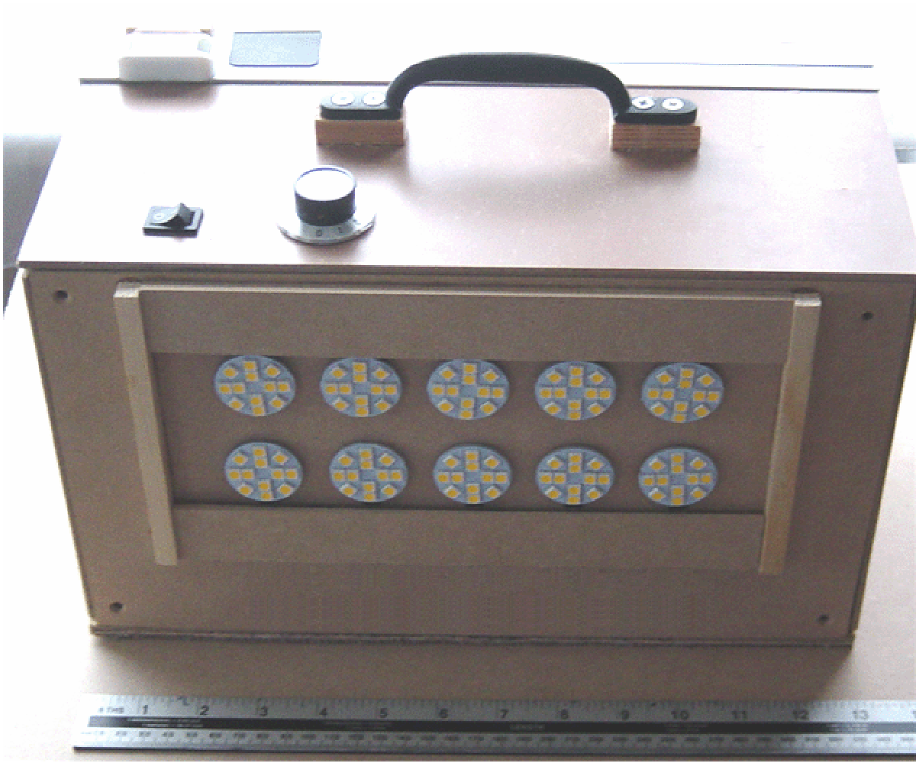
When closed over, the face of solar panel P1 faces that of solar panel P2, protecting both when the unit is being carried.

An early prototype of this style of construction with the panels open, looks like this:



A magnetic catch is used to hold the hinged panel securely closed when the unit is being carried and a small flap is attached beside the magnetic catch to overcome the slightly excessive looseness of the hinges. The unit does not need to be as deep as this experimental model was made.

The front view of the unit, ready to receive the frosted plastic cover for the LED arrays, looks like this:



The underside of the unit is covered with a soft protective layer to ensure that it does not scratch any surface on which it is placed. In order to avoid the need for overcharging circuitry, this unit has six battery packs and so, having ten LED arrays, the duration of lighting is about the same as that of the desk lamp, although obviously, the light output can be much greater. With the greater lit area of ten LED arrays, a lower actual current can be used while still providing a good level of lighting.

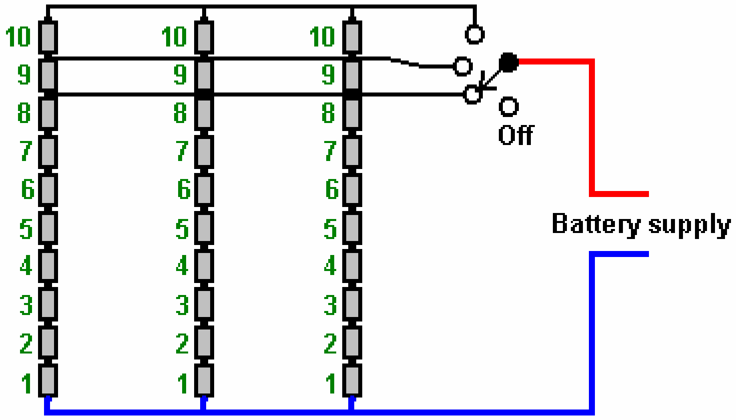
With fully charged batteries switched to the ‘boost’ setting, this unit puts out more light than a 100-watt incandescent bulb powered by the mains. Tested in daylight, that looks like this:

Let me stress again, that these units are not difficult to build and they don’t call for any great knowledge of electronics.

Alternatives:

While the systems shown above are effective and reasonable cost, it is possible to make them more efficient. With battery packs of ten NiMh 1.2V AA cells, when fully charged, we get more than 13-volts, when we actually want 9-volts for effective lighting. We get this by using two transistors to drop the voltage down to 9-volts. The current flow is about 135 milliamps and so, the voltage drop of 4-volts at that current flow is a power loss of 540 milliwatts, which is a significant percentage of the power used to generate the lighting.

By arranging things in a different way, we can reduce that power loss very considerably, IF we don’t mind the user being involved in controlling the lighting level. We could do this by tapping into our 10-battery pack and using an extra 3-way switch which allows us to start off with 8 batteries and when the voltage starts to drop, switch to 9 batteries as the extra fully-charged battery would make a major difference to the lighting. Then when the voltage of the 9 batteries starts to get low, the tenth battery can be switched in:



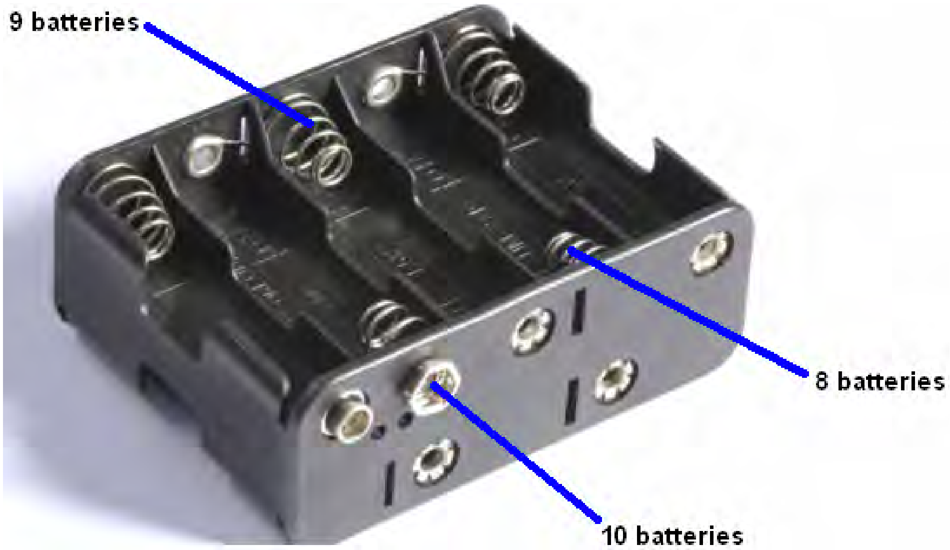
Whether or not this is worth doing is a matter of opinion in spite of the longer and/or brighter lighting. With 8 batteries in use, the power saving is 350 milliwatts and with 9 batteries the power saving is 175 milliwatts. The lighting power is 1215 milliwatts, so these represent 29% and 14.5% of that power. If it is decided to use this arrangement, then the battery boxes can be tapped with additional output wires connected between batteries 8 and 9 and between 9 and 10.

The operational sequence would be:

1. Eight batteries switched in: variable light control.
2. Nine batteries switched in: variable light control.
3. Ten batteries switched in: variable light control.
4. Boost switch closed: fixed lighting level as batteries discharge to their minimum level.

Each of these switched levels gives a new lease of life to the lighting system, but it does require the intervention of the user, although that intervention is very minor.

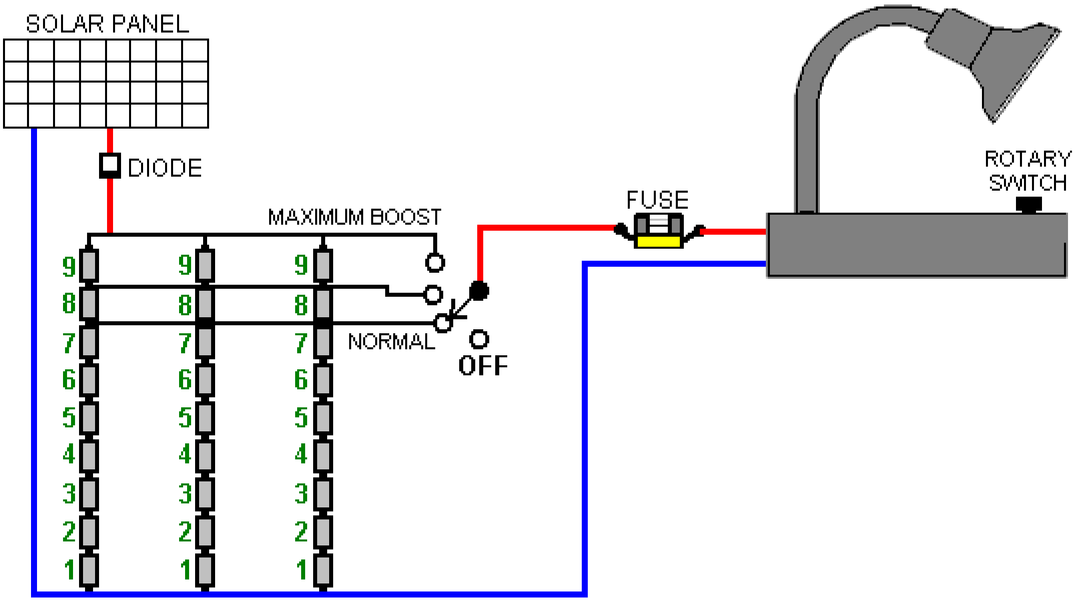
It does not matter whether it is the Plus end of the battery chain, or the Minus end which is switched. The way that the battery boxes are constructed, actually make it more convenient to make the two extra connections at the Minus end of the stack:



Medical usage

The applications of the solar desk lamp shown above are intended for home or office use. There is one other serious lighting requirement and that is for doctors working in isolated rural areas, far from any electrical grid but also, very far from fuel supplies for running a conventional generator which is the only known option for most of them. For example, it can take a doctor two days of travelling to get some more generator fuel. If we apply a slight alteration to the desk lamp and sacrifice the long period of lighting, we could boost the light output from 1000 lux right up to 2,700 lux for an hour or two of very brightly lighting. I can see no reason why two or three of those would not give more than adequate light for night time emergency surgery when placed on stands or suspended from the ceiling. Being self-contained and mobile, an assistant could hold and aim one to illuminate exactly where the light is needed.

The basic solar desk lamp operates off seven 1.2V batteries in series. Eight batteries in series would boost the light level to 1730 lux at the cost of much higher current draw and reduced period of lighting. Increasing the batteries to nine would raise the light level to a massive 2,700 lux with a current draw so high that there might only be lighting for perhaps one hour, but that doesn’t matter in an emergency where a life could be saved. To achieve this emergency level of lighting all that is needed is an ordinary 4-way rotary switch which replaces the On/Off switch as it can do that job as well, otherwise the construction remains identical. The arrangement could be like this:



360 Degree Lighting for Africa

The desktop lighting unit described above is very effective for lighting in cold areas where houses have windows with glass in them and where the roof does not project much beyond the house wall. However, housing style is very different in places like Africa where strong sunlight is experienced all year round and so a house roof is likely to project well beyond the wall in order to give improved shade for outside seating.

Anna Brüderle's "*Solar Lamps – Africa*" marketing research published by GIZ GmbH Uganda, has raised many previously unknown facts which should result in physical design changes. To date, I have produced three solar prototype lighting units, but these have been based on recharging using light coming through a glass window. That is not really possible in the African environment surveyed, as it shows:

1. Using a solar panel indoors is not possible due to lack of windows and major roof overhang.
2. Using a solar panel light being recharged outdoors is liable to have it stolen.
3. Using an outside solar panel connected by a wire is liable to damage and/or child injury when at play.

The survey-area lifestyle has the following characteristics:

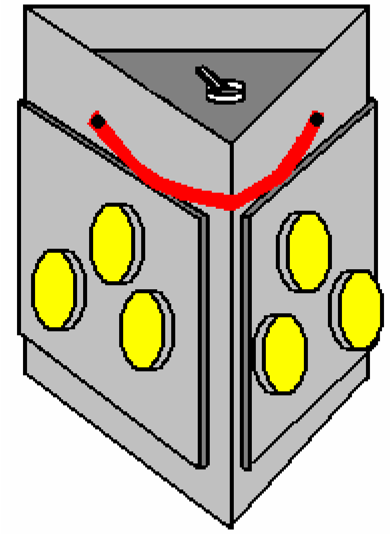
1. Seven people living in one building is not unusual and so 360-degree lighting is preferred.
2. The kitchen is normally separate and has no windows and yet needs meal-preparation lighting.
3. Burning a fuel for lighting is liable to cause poor health from the fumes produced.
4. Child education is hindered by lack of lighting.
5. Light usage is usually 3 or 4 hours at night plus 2 hours in the morning.
6. Tests with 100 lumen lighting level have been considered to be satisfactory.
7. Lamps are normally placed on the dining table during meals and hung from the ceiling at other times.
8. When carried outside, a narrow forward lighting arc of say, 90-degrees is preferred for safety.
9. Units with variable lighting levels are preferred but why is not specified – probably light duration.

In these houses, there can be internal walls which do not reach the ceiling so that light in the central room spills over into the additional rooms.

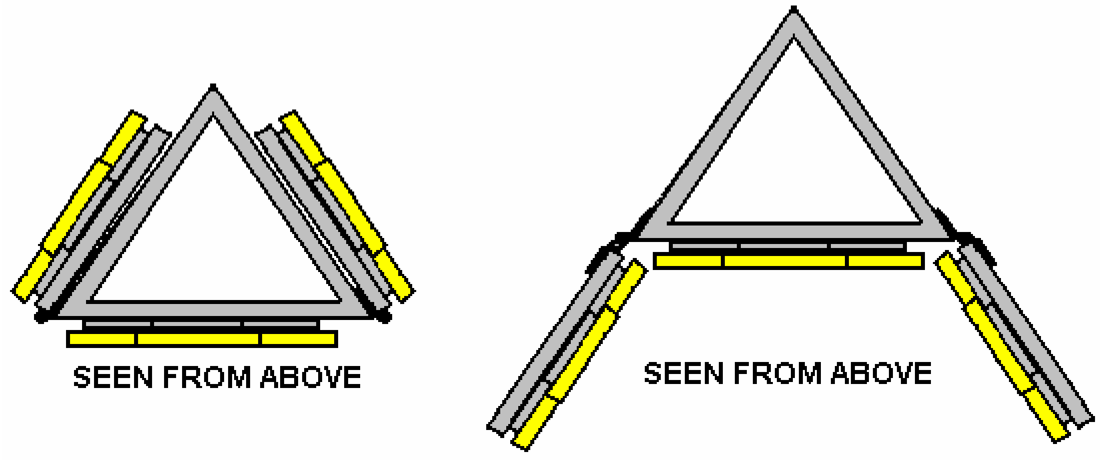
These features call for a lighting unit which is:

1. Able to provide 360-degree illumination.
2. Able to give a restricted 90-degree lighting arc when used outside.
3. Stable when standing on a horizontal surface.
4. Able to be carried comfortably.
5. Able to be suspended from a ceiling.
6. Able to provide considerably more than 100 lumens for the lighting periods used.
7. Is cheap enough to be bought.
8. Is very robust.
9. Is free of any glass components as hurricane lamp accidents are mainly cuts from broken glass.

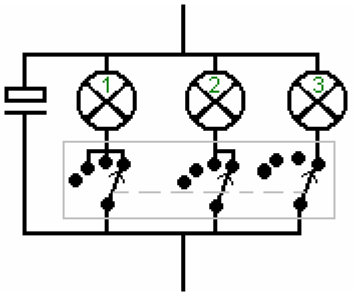
It is possible to design a lamp which meets all of these requirements although low cost is the most challenging requirement. To meet the user's needs, it might be possible to use a housing like this:



The triangular shape makes for easy construction and is very robust from an engineering point of view. It also cuts down the number of faces needed for 360-degree lighting to just three. The versatility is increased greatly if two faces are hinged:

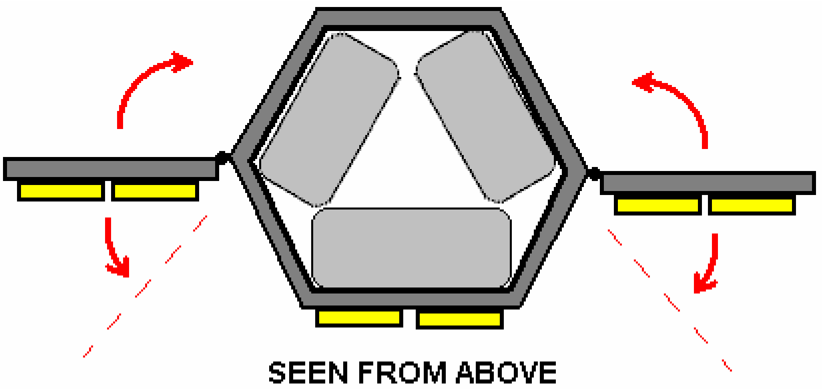


This arrangement allows two faces to be aligned with the fixed front face, giving all horizontal lighting in one direction which is a very, very bright arrangement. The two faces can be moved further around to give the wanted narrow forward beam for walking outdoors. If desired, the lighting level can be controlled by making the On/Off switch a three-pole four-way rotary switch:

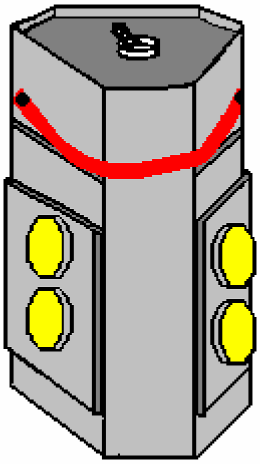


This arrangement gives Off, One panel, Two panels and Three panels of illumination, but it could also be that instead of switching off an entire panel that the switching illuminates one LED array per panel, two LED arrays per panel and three LED arrays per panel.

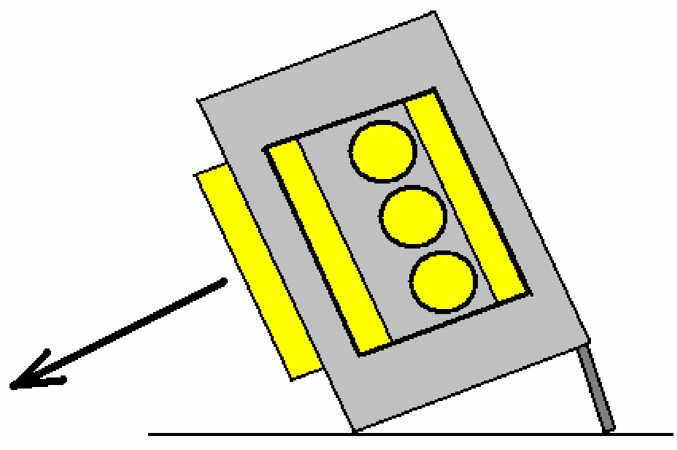
If ordinary 10-battery holders are used, then the lamp housing can be made more compact as the corners of the triangle are not needed. The battery packs fit in like this:



Giving a compact hexagonal shape which is strong and has the same lighting capability. The sides extend above the top and below the base so that the unit can stand on a flat surface either way up. The hinges need to be stiff so that they hold their position when set to the desired angle.



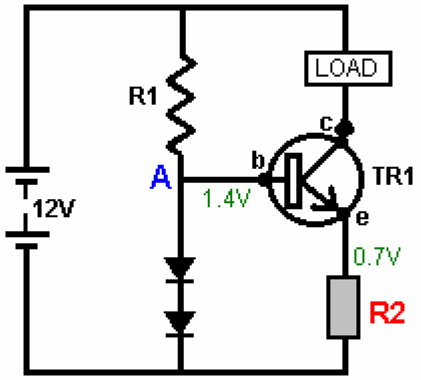
The addition of a simple hinged flap to the base allows a tilted option which imitates the downward lighting style of a desk lamp:



The Chinese LM2587 DC-DC converter from h-quality_electronic selling on eBay in October 2015 for £3.17 including postage, has COP>1 performance:

Ten LED arrays are brightly lit by it with just a 2.88 volt input. Measurements using three NiMh batteries connected in series, indicate an input of 800 mA at 3.33 volts (2.664W) driving the 10-LED array displays with 389 mA at 10.3 volts (4.01W) which is COP=1.5 and has the advantage of reducing the number of batteries needed for good LED array lighting. In practice, four batteries in series are used. This converter also charges ten NiMh batteries from 10.5V to 13V (falling eventually to 12.5V) in just 30 minutes at 50 mA current draw.

A very useful addition to this sort of lighting system is using a simple constant-current circuit to control the current draw and give a steady, unchanging lighting level throughout the entire period of illumination. I have found that zener diodes do not perform well when supplied by batteries with gradually falling voltage. A much better method of getting a reference voltage is to use ordinary diodes and use their normal voltage drop as a reference.

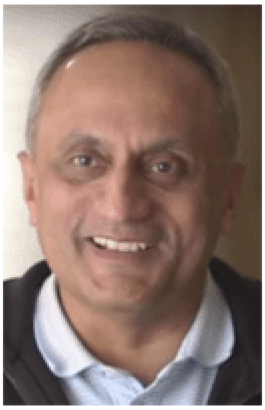


As the transistor TR1 has a voltage drop across it's Base - Emitter junction equivalent to the voltage drop across one diode, we use two diodes to create a voltage reference level and so maintain a 0.7 volt voltage drop across resistor R2. R1 is chosen to give about 3 milliamps of current flowing through point "A" and the diodes can be any silicon type, perhaps 1N4148 diodes. The transistor needs to have a high gain and be able to handle the desired current flow through the load. A 2N2222 transistor appears to work well in this circuit. Resistor R2 is chosen to give the desired current flow, forcing that current flow through the load (provided that the battery can supply that current). The load can be the DC-DC converter shown above and the battery voltage can quite easily be 5 volts. If there is concern about the power handling ability of a 2N2222 transistor, then two or more can be used in parallel with the Bases connected together, the Collectors connected together and the Emitters connected together.

It may well be possible to charge a second battery pack when the lights are on and then, when the lights are switched off, to use that second battery to recharge the main battery pack. Alternatively, a 10 watt solar panel, as used with the desk light, can be used to recharge the battery pack through a length of low-resistance cable and a plug and socket. There is also the possibility of providing a USB socket for recharging mobile phones. It should be able to supply 5 volts at 500 milliamps and draw no current when not in use. The user should be alerted to the fact that extensive use of the USB socket may reduce the power in the battery pack used for powering the lighting.

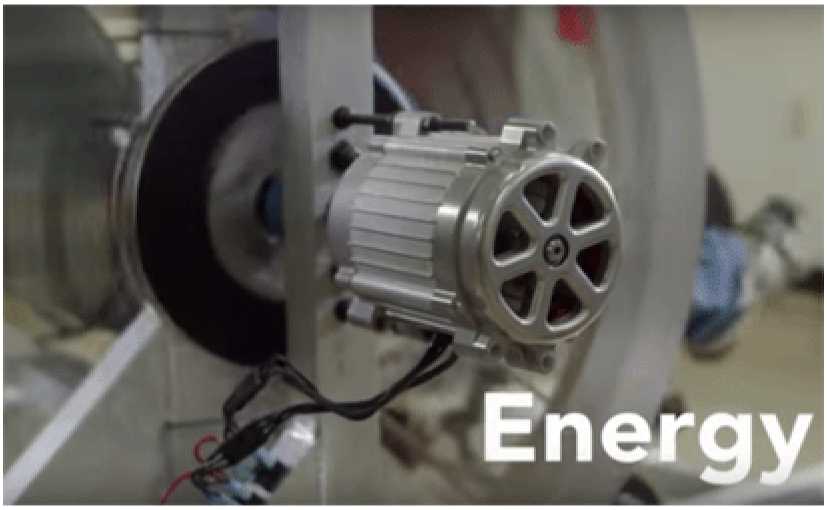
The prototype worked very well indeed when carried out of doors in a totally unlit and unfamiliar place. If the suspension cord is made longer and an additional hook is provided near the base, then the unit can be suspended indoors with all of the LED arrays facing downwards, which with their 160 degree angle of illumination would give excellent 360 degree lighting.

Manoj Bhargava

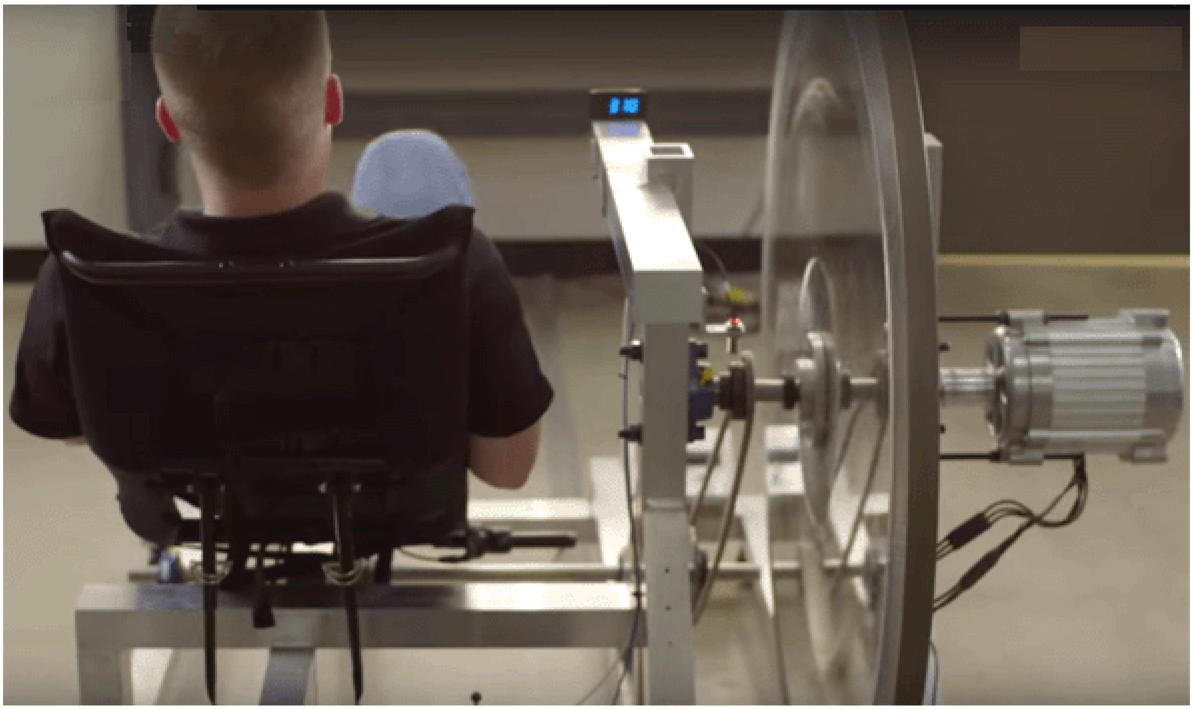


Throughout this ebook there are many designs for generating electricity, getting pure water and my websites also have some information on health issues. These things have all been approached from the point of view of you, as a single individual, doing something in spite of having very limited finance, workspace, tools and skills. There is a very interesting and inspiring video at http://billionsinchange.com/film which describes some of the work of Manoj Bhargava and his colleagues. Manoj produced a drink called “Five-hour Energy” which became a major commercial product, leaving Manoj with four billion US dollars. That has given him the freedom to use his common sense and practical attitude to start to deal with the major issues of half the population of the world – free-energy, clean water and health improvement. With his finance, he works with much larger solutions to these problems and some of his designs are most interesting. He avoids any mention or use of unconventional systems.

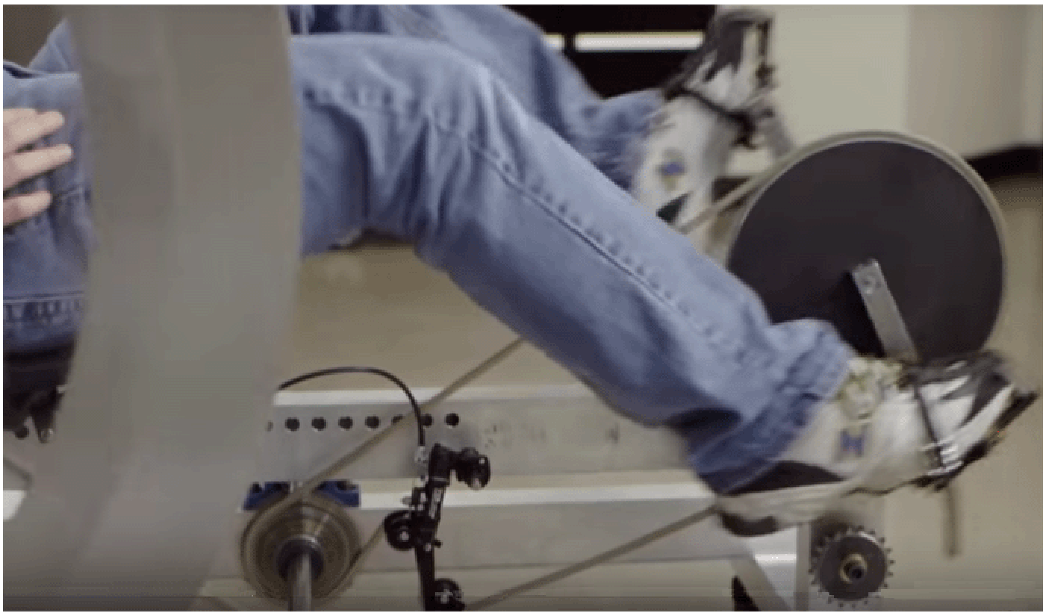
For the provision of electricity, he proposes the use of an adapted bicycle which spins a generator and charges a battery which can slowly charge mobile phones and provide lighting. It is said that one hour of pedalling can produce 24 hours of (low-power) electricity. His design looks like this:



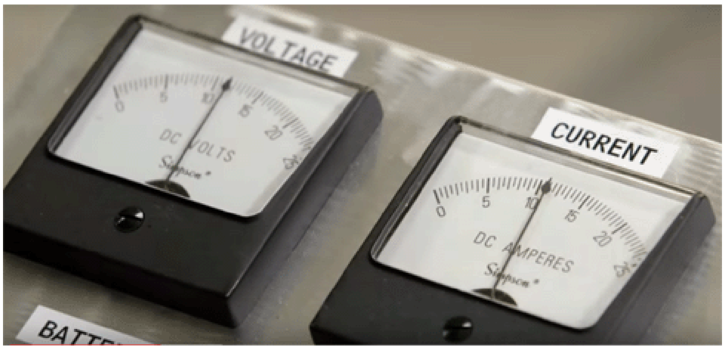
This is the generator which is spun by belt gearing from the pedals. The wheel with the large rim forms a flywheel and although he does not mention it, the flywheel causes an energy gain. The basic build looks like this:



the cyclist pedals in a reclining position and the belting drives the gearing which spins the generator shaft:



The design produces a good deal more electricity than I would have expected:



VOLTAGE
0
5
10
15
20
DC VOLTS
Simpson
CURRENT
0
5
10
15
20
DC AMPERES
Simpson

These metres show more than 100-watts being generated. However, production cost is always a major factor in these things, especially since the people who need them most are the people with least money. Perhaps a version which is driven by an existing bicycle might ease the situation – that method is already used for some exercise equipment. Another factor which might be missed by designers is the fact that the people needing this equipment are labourers and will be tired after a long, physical working day. Of course, the pedalling would be less effort for them due to their much higher muscle strength. The addition of two small motors like Chas Campbell does, would probably make the design self-powered and do away with most of the construction – pedals, belts, seat, etc.

In August 2016, Manoj found that his plans for shipping completed bicycles into India from his newly-built factory in Singapore, was effectively blocked off by import restrictions. So, He is building a factory in India and he expects production there to be implemented in 2017. He also found that a number of changes needed to be made because it is primarily women who are free to do the pedalling. The changes include a reduction in size to allow for smaller people, a chain guard to protect long clothing, a battery ,low-voltage setting of 11.5 volts, a reduced gearing to allow easier pedalling, and finally, a detachable battery so that the power can be mobile. The main application is lighting, although I suspect that the lighting efficiency is not as high as the 1000-lux for just 1.5 watts of the LED designs shown in the previous section of this chapter.

Low-cost Cooling Systems

When most people think of air-conditioning systems they think of large pieces of equipment which are expensive to buy and expensive to run and which are mounted in one fixed location. While those systems are certainly effective (although, often noisy in operation), there are other ways of improving living, travelling and working conditions. Ways which are not very expensive to buy and which are not expensive to run. Many people have made effective air coolers and shared their designs using web videos, and I should like to thank them for showing what they have achieved.

Simple cooling systems can use two different methods of operation. One method is to use ice which has been produced using an ordinary refrigerator or freezer (those being very common in places where air-cooling would be considered an asset). Another method uses the well-known principle that when water evaporates, it draws heat from its surroundings as part of the process.

The general idea is to cool some air and then use a fan to blow that cooler air to where it is most effective for the user. Typically, cooling is most needed inside buildings and inside vehicles. Inside buildings, mains electricity is often available. Inside vehicles, twelve-volt or similar levels of DC power are generally available. In both locations, a solar panel (possibly aided by a car battery for night time operation) can operate a useful system.

What we are talking about here, is a small system which will not be as effective as a large commercial unit, but yet is something which can make a great improvement in a small area. Something which does not seem to occur to many people is that you can have more than one of these units operating in a room or vehicle.

While I am delighted that people have shared their simple designs on the web, they usually assume that the components which they have used are available to everybody, and that is very much not the case as the items which are readily available locally vary enormously at different places around the world. For that reason, I should like to discuss the basic principles used so that when any chosen design uses something which is just not available locally, you can choose a suitable alternative which is readily available locally at low cost.

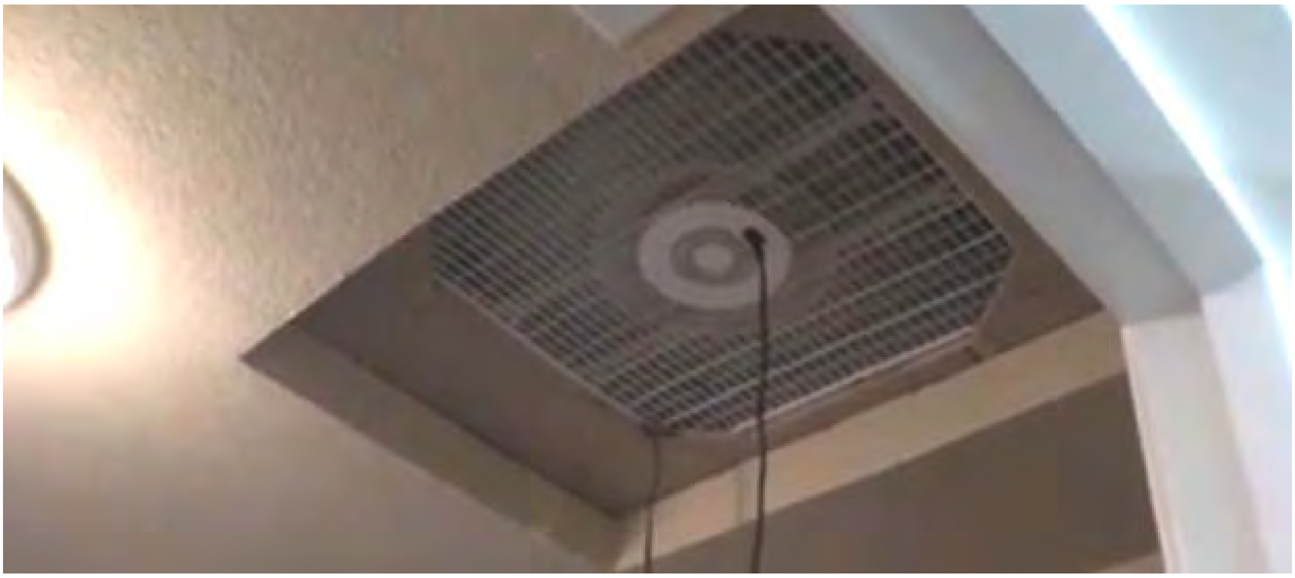
Let us start with indoor cooling. The unwanted heating comes mainly from the sun shining in through windows, and from heat leaking in through the walls because the outside of the walls is being heated by sunlight falling directly on it or by hot air flowing along the outer surface of the wall. Of these two main sources of indoor heating, the sun coming through the windows is generally the greater source of heat.

If a room has one or more windows facing the sun and one or more windows which do not face the sun, then a first step might be to use shiny silver-faced insulation cut to exactly fit the windows through which the sun shines. Curtains can generally hold the insulation in place on their own, but if that is not convenient, then a few small pieces of adhesive tape work adequately and can be used again day after day. The outer shiny layer reflects most of the sunlight back out of the room. The outer surface of the insulation sheet heats up as not all of the light is reflected, but the insulation layer stops most of that heat actually entering the room, resulting in a major improvement in the room temperature, although the light level is reduced considerably as well. This is suitable for people living in apartment blocks where there is no convenient access to the outside of windows.

In the case of people living in bungalows or other low buildings, the use of shade should not be overlooked as it is a very effective way of reducing temperature. This effect is even very noticeable in cooler countries on sunny days as there is a very marked effect driving down a road which has large trees on the same side as the sun. With the car windows open, there is a very considerable drop in temperature when the car enters the area shaded by the trees. I am not suggesting growing trees to give shade as that is not convenient for most people, but a simple overhang or a temporary or retractable awning may be possible to block direct sunlight from coming in through the windows. An awning or overhang has no running costs.

Let's take a look at one of the systems shown on the web. This one is being used to lower the temperature in a house with a floor space of 1,700 square feet (158 square metres) and the video presentation is at https://www.youtube.com/watch?v=6ScZiMiva9M and deals with a house where the outside daytime temperatures exceed 100 degrees Fahrenheit (38 degrees Centigrade), making the indoor temperatures uncomfortable. With his cooler running and the outside air 90F (32C) the air entering the house is 69F (20.5C) which means that the warmest place in the house is around 75F (24C). As hot air rises, the hottest place in the house is the highest point and very sensibly, he has mounted an extraction fan which pulls the hottest air out of the house and pushes it into the attic (which is open to the outside and so vents to the outside air).

For the system to be effective, all of the windows and doors are kept closed except for the one which has the cooling system mounted on it. This blows the hottest air out of the house and at the same time, draws fresh air in through the cooling system. You can see the attic fan mounting here:



The entering air comes in through a large window which has evaporative pads clamped to the window frame by a simple timber mounting system:

The pads are kept wet by droplets of water pumped to the top of the window by a small submersible pump submerged in a large plastic storage box filled with water:

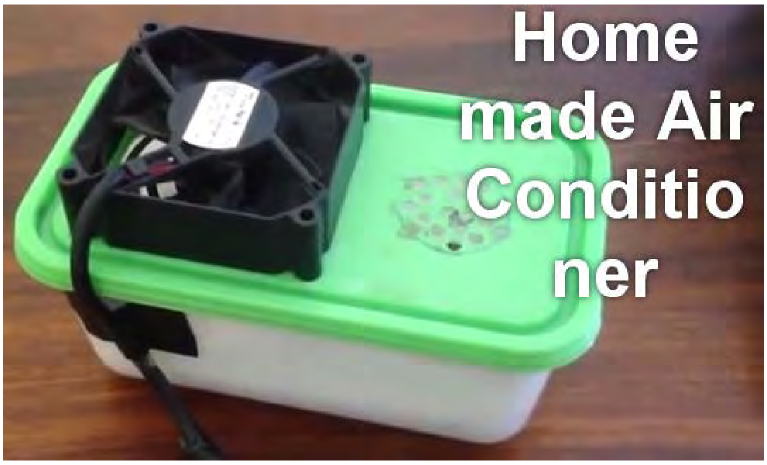
Excess water is returned to the reservoir by two short lengths of plastic guttering as shown here:

The particular fan and pump used draw a total of 120 watts, and so as one "unit" of electricity is 1000 watts for one hour, running the system all day and night is a power usage of 120 /1000 x 24 = 2.88 Kilowatt-Hours per day. The construction costs in America in 2013 were about US $60.

If solar panel power is to be used with a lead-acid battery, please remember that the battery is only 50% efficient, which means that it will only return half of the current that you put into it. Also, please remember that solar panels are rated for bright sunlight shining directly on them at exactly 90-degrees to the panel and in normal operation, the panel output is far less than the retailer's claimed wattage, not to mention the fact that the panel will only be operational during daylight hours. As against that, many such installations do not need to be run day and night and so solar operation may be quite economical. Also, 120 watts is a large amount of input power and could almost certainly be reduced for smaller installations.

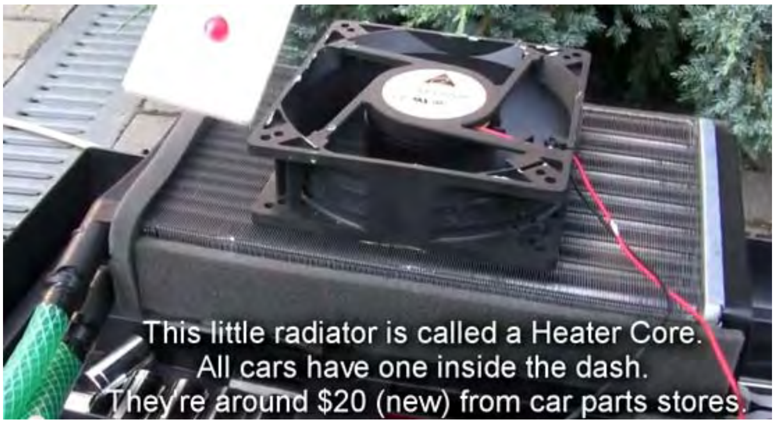
It is not unusual for the cooling of a single room to be satisfactory in many situations. For this, using a very small self-contained unit is often considered to be adequate. These units generally use a fan from an old computer, typically, running on 12-volts and drawing about 4-watts. For the cars which still do not have air conditioning, a fan of that type is very convenient as it can run directly off the 'cigarette lighter' socket or from a direct wire connection through a fuse, to the car battery. For indoor use, any tiny 12V mains power unit can power the unit for minimal cost.

These units have been made in all sorts of shapes and sizes and by all accounts, do very well when easing excessive heat. This very small unit uses a 12V 3.6-watt computer fan blowing air into a small insulated box containing ice and can be seen at https://www.youtube.com/watch?v=6pwHvXZr1A4. In spite of being rated as a 12-volt unit, the fan can actually run on a low-power USB socket. Cold air exits from the holes drilled beside the fan:



This one is at https://www.youtube.com/watch?v=Wf2Zhu4Fmzo uses a 21-inch (535 mm) square box fan with a simple evaporation system attached to it:

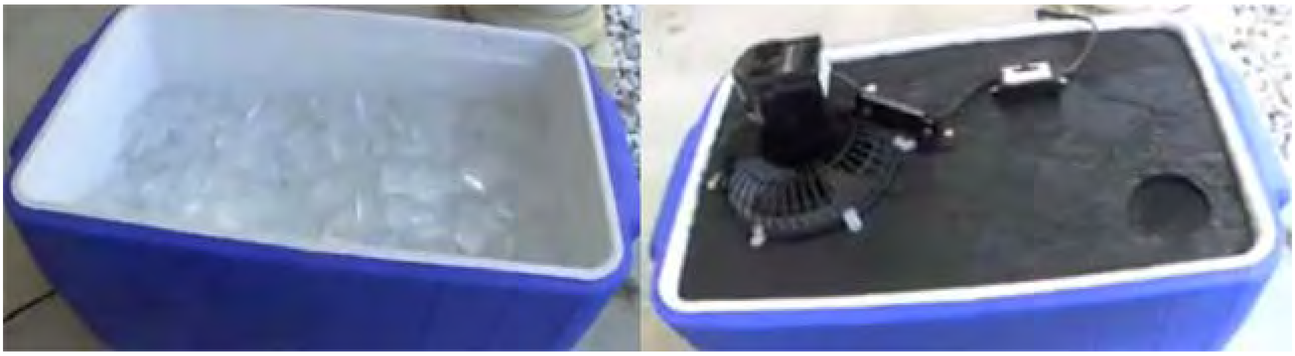
This one at https://www.youtube.com/watch?v=gawOWyhtthU also uses a computer fan:



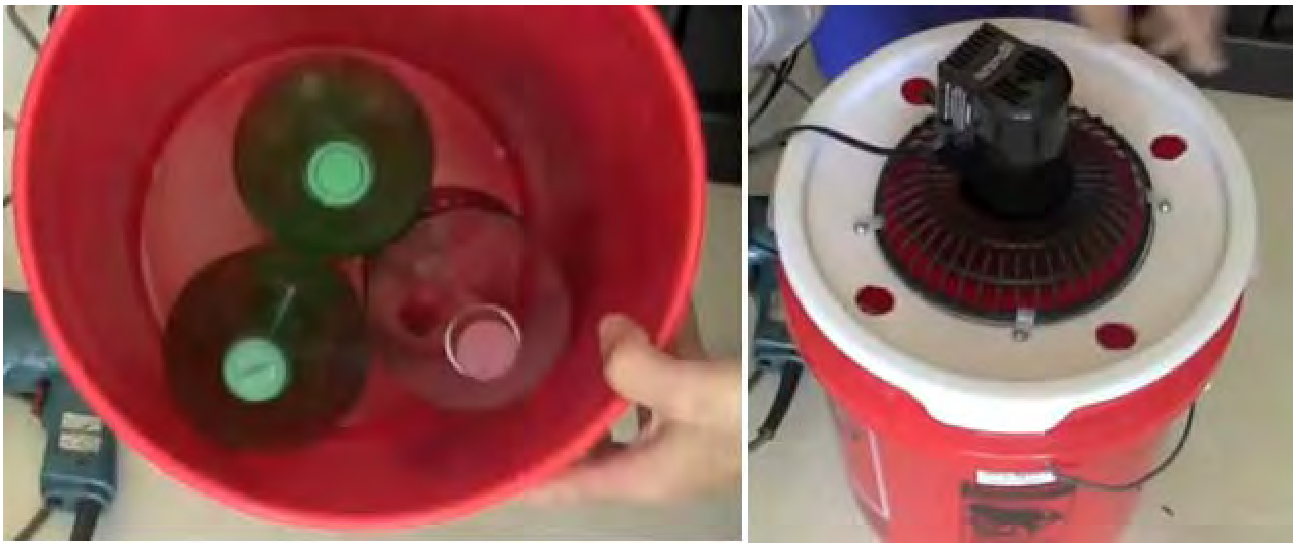
This little radiator is called a Heater Core.
All cars have one inside the dash.
They're around $20 (new) from car parts stores.

This one at https://www.youtube.com/watch?v=LiS0W5peFBk uses a Wal-Mart battery-powered fan which means that with a solar panel to recharge extra rechargeable batteries when the unit is in use, the unit could be very, very cheap to run. An ordinary ice-box is used, so perhaps cold drinks are a possible additional option:

Also using an ordinary ice-box the https://www.youtube.com/watch?v=N1NwXBXpShQ unit has a wooden push-fit lid and uses a car fan:



The unit at https://www.youtube.com/watch?v=NUhs_1puHk0 is intended for use inside a car, although obviously, it could easily be operated inside a house using a small 12-volt mains unit. The preferred coolant is 2-litre plastic bottles filled with water which has been frozen solid in a freezer. The builder states that the bottles will cool a car down faster than ice does and the bottles also provide a longer period of cooling than ice can:



The fan is set to blow air into the container and the cold air exits through the four holes drilled around the fan. This design suggests that as a temporary measure, standing some frozen 2-litre bottles in front of an ordinary fan could well provide effective cooling in a room. Using ice or bottles of frozen water is energy efficient as refrigerators and freezers are generally about 300% efficient. That is, the cooling energy is three times greater than the electrical energy used to achieve that cooling.

These are only a few of the many ingenious and simple designs which could make life much more comfortable in conditions which are generally considered to be excessively warm. A little time spent examining these and similar units shown on in web videos should give you confidence to build your own, or if you prefer, to design and build your own simple cooler system.

Sensible Building

There is a famous American Architect called Michael Reynolds. He has a very low opinion of conventional housing which he considers to be a "compartment" which is wholly dependent on outside power sources. His opinion is justified. He produces buildings which have been named "EarthShips" by his wife and the name has caught on world-wide.

The objective is to make a home which has no utility bills at all. A building which collects its own water and uses that water several times. Generates its own electrical power. Provides its own heating and cooling. Grows some of its own food, and uses materials many of which have been disposed of by previous owners - vehicle tyres, aluminium drink cans and glass bottles. An EarthShip can be a stylish and comfortable home:

Although, obviously, the overall cost of the structure and furnishings depends on the quality chosen by the owner.   This particular EarthShip is one shown in the film "Building Off The Grid" which can be found on the peer-to-peer network, took fifty volunteers four weeks to complete the basic structure and then another team of workers were paid to supply and install the fittings and fixtures.

The structure faces South and has twelve large solar panels mounted along the top of the greenhouse area. Although this picture does not show it, there is a drainage ditch along the back of the property to divert heavy rainwater coming off the protecting hillside behind the property:

The walls of the property are seven feet thick (2.13 metres) in order to allow the use of fairly simple materials and more importantly, to provide thermal mass which keeps the inside of the building warm in winter and cool in summer. There are no significant bills for heating or cooling and normal electrical equipment is run from the solar panels.

The design of the electrical system is elderly and as shown, it requires lead-acid batteries to be replaced about every four years. A smaller system driving DC battery pulse-chargers would provide fast battery charging and the batteries would never have to be replaced. However, this particular house was built using twelve large solar panels. Initially, three were used to provide electrical power during the building period. These were just propped up against the hillside near the battery box which contains control equipment, a battery bank and a mains inverter:

The battery box used during construction is very simple:

The overall design is set up for construction by unskilled workers under the supervision of a few experienced people, but let me point out that this is a Civil Engineering project and so a reasonable level of understanding is needed before you build one for yourself.

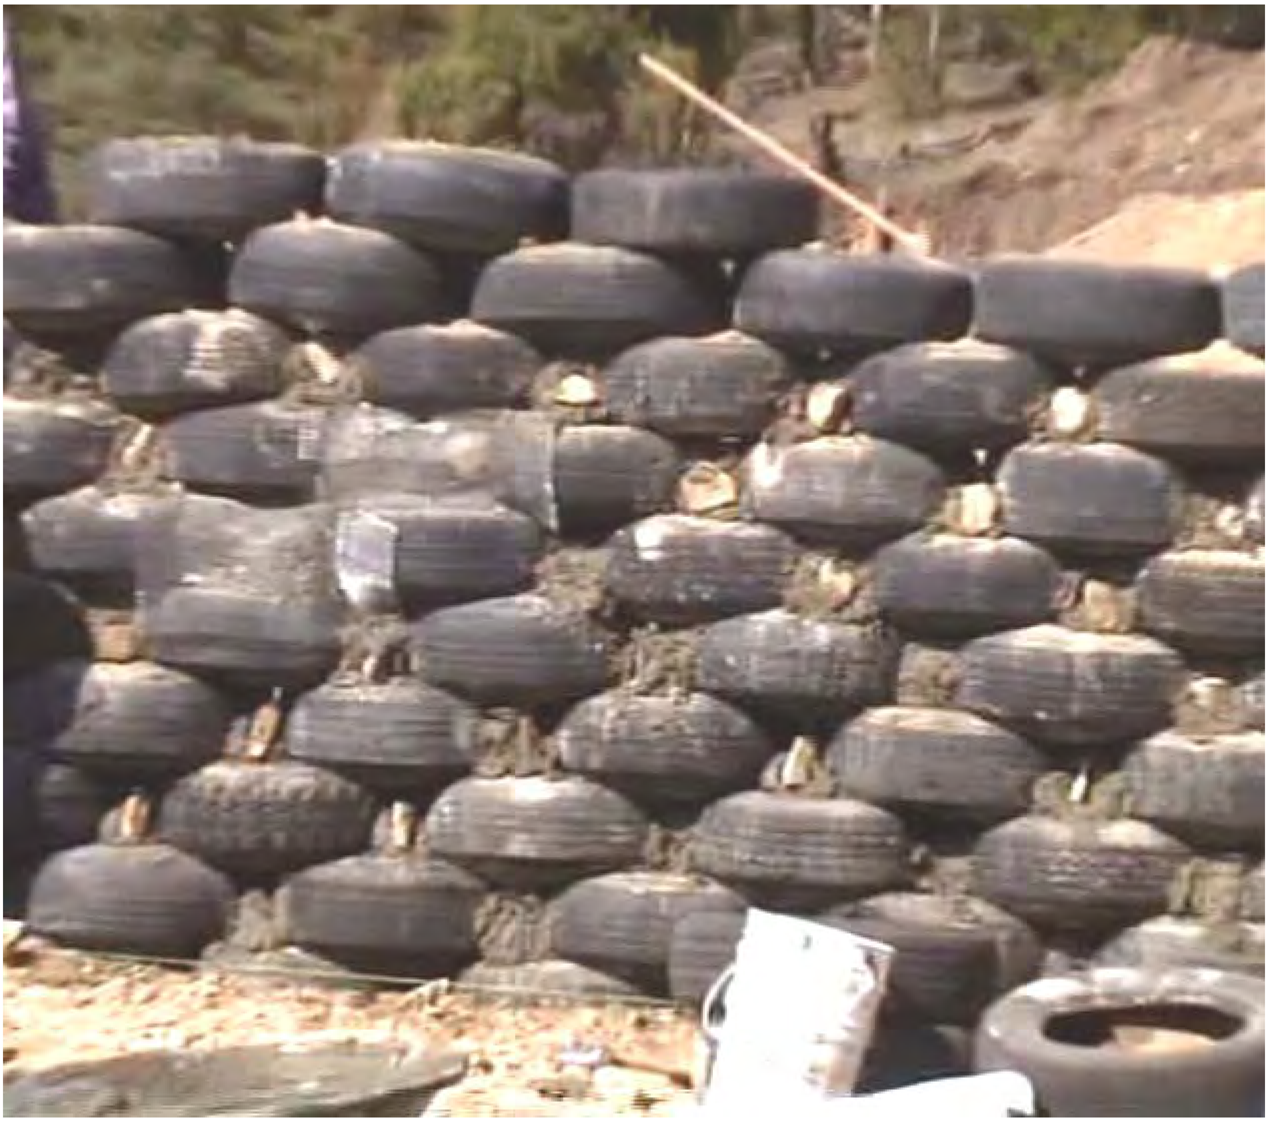
For example, the roof spans across the gap between the outside walls. The loading on any support beams increases with **the cube** of the distance between those walls. That means that if you were to double the width of the room, then the support needed to hold the roof up increases by a factor of eight times !! This can, of course, be achieved, but you really need to be aware of it. In this particular building, the roof is held up by numerous tree trunks which have been stripped and prepared for the job:

These beams are very heavy and are quite capable of causing serious injury if not handled carefully and sensibly. They form the joists which support the roof and there is a gap of about one foot between them, so many of them are needed. They are secured to the top of the wall by steel rods driven through them and on into the wall.

The main construction is with vehicle tyres and about a thousand are needed for the building. Each is filled with earth which is compacted carefully and then they are stacked in a staggered bank and grouted in place using mortar. In passing, most American get confused with concrete products, so to clarify:

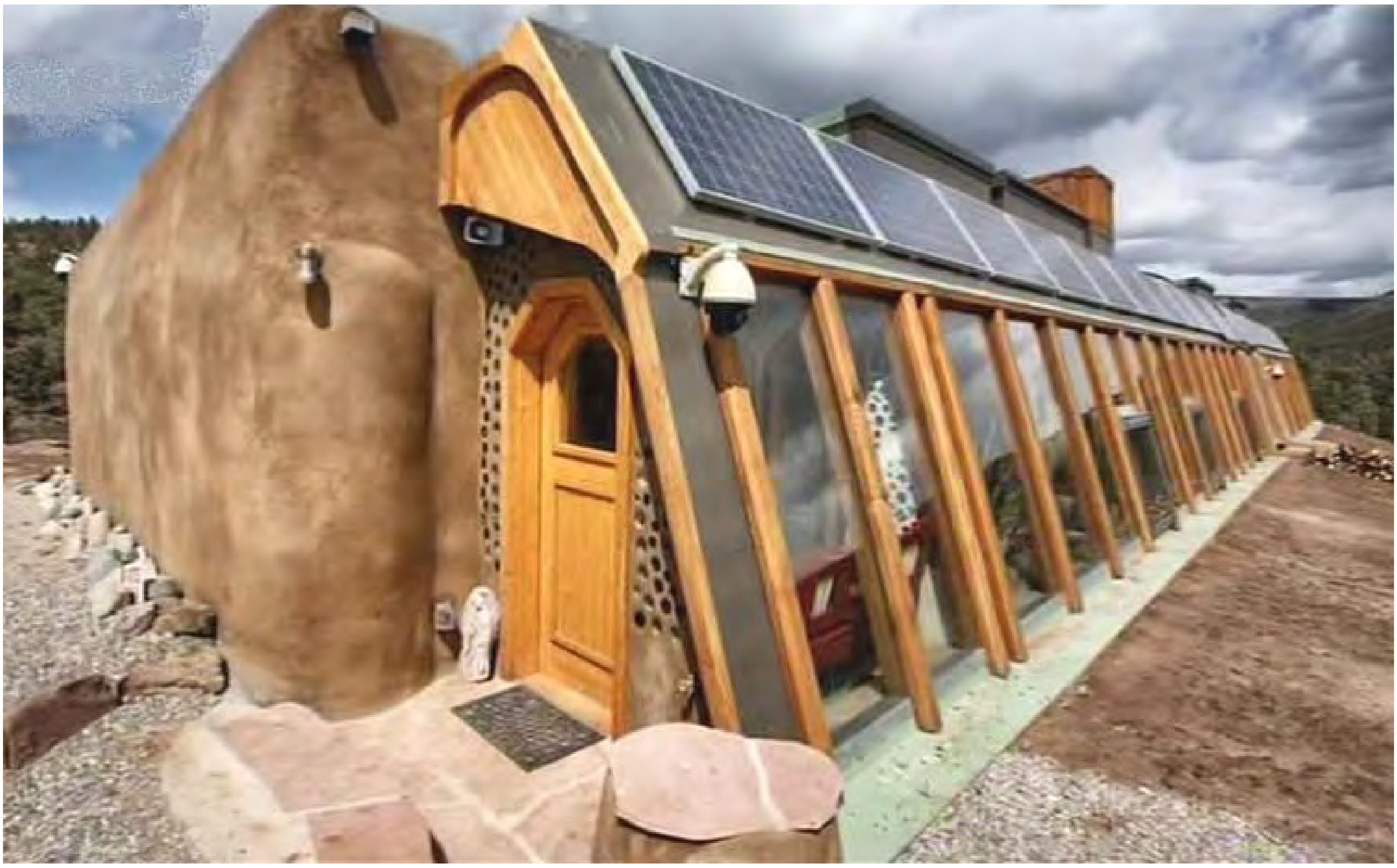
1. Cement is a grey powder material.
2. Mortar is a mixture of cement and sand, wetted with water, which sets into a solid. It is normally used to fill the gap between concrete blocks or clay bricks.
3. Concrete is Mortar which has pebbles mixed into it.

Also used in these constructions is adobe which is mud and straw mixed together. Properly made adobe dries into a solid block and is used in hot dry countries as a main building material, but it needs to be waterproofed against future rain unless a temporary structure is sufficient.



The tyres are overlapped in successive rows, forming a stable structure and then grouting is applied between them. The outside is enclosed in an earth bank and the inside is later smoothed over.

This style can be seen at the back door alongside the greenhouse area:



The constructional details can be found in the books by Michael Reynolds “Garbage Warrior”, “EarthShip”, “Comfort in Any Climate”, etc. or full constructional plans can be bought direct from Michael.

Water is collected from the roof, filtered and then held in massive plastic tanks which have a total capacity of 6000 US-gallons (22,700 litres). There are no pumps as all water flows under gravity. Water used for washing is then used for toilets and then on to water plants which grow food.

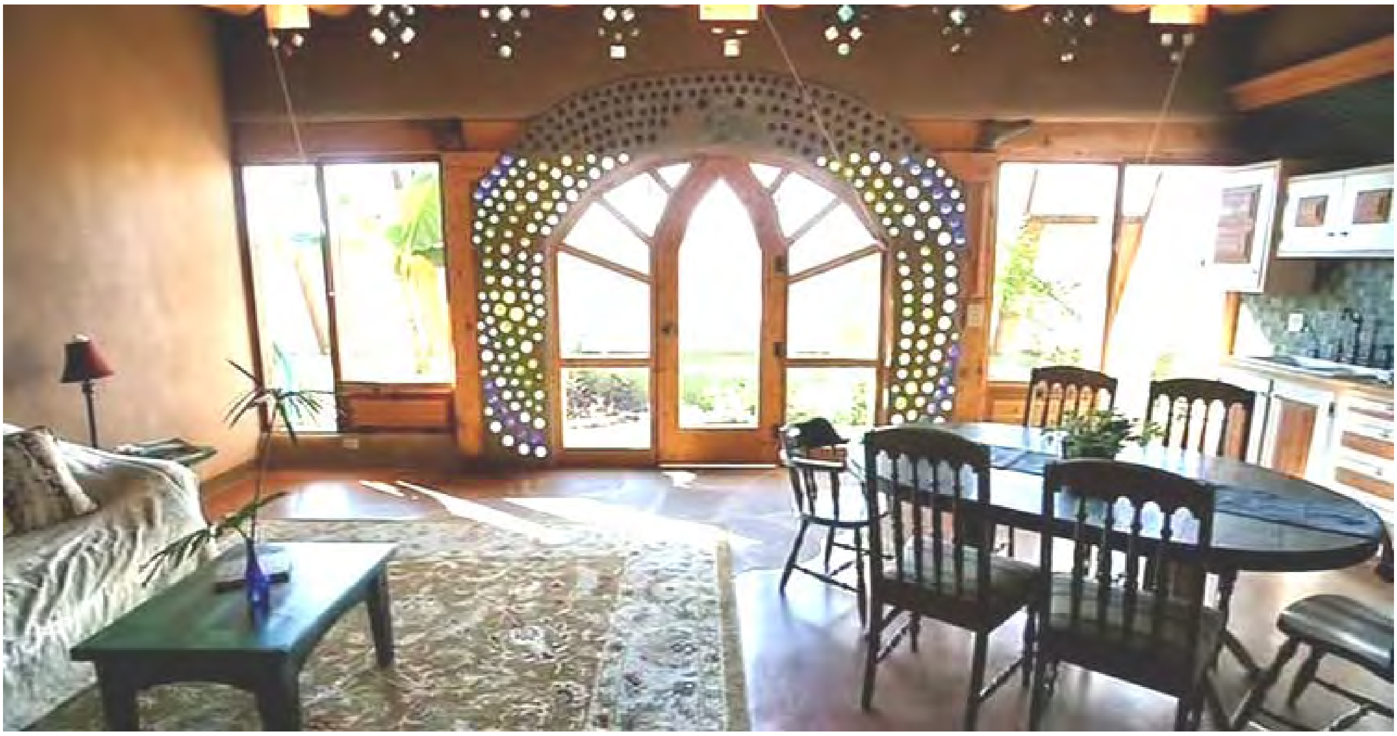
The positioning of the tanks is important as they have to be just below the roof so that rainwater flows into them under gravity and yet they have to be higher than shower-heads for the same reason (unless a pump is used for showers). A simple filter is used to remove any blown material which finds its way into the water intake.

For all that unskilled people can do most of the work, there are a number of trade skills which are needed – plumber for the piping, electrician for the electrics, engineer for levelling and concrete work, glazier for the double glazing units, etc.

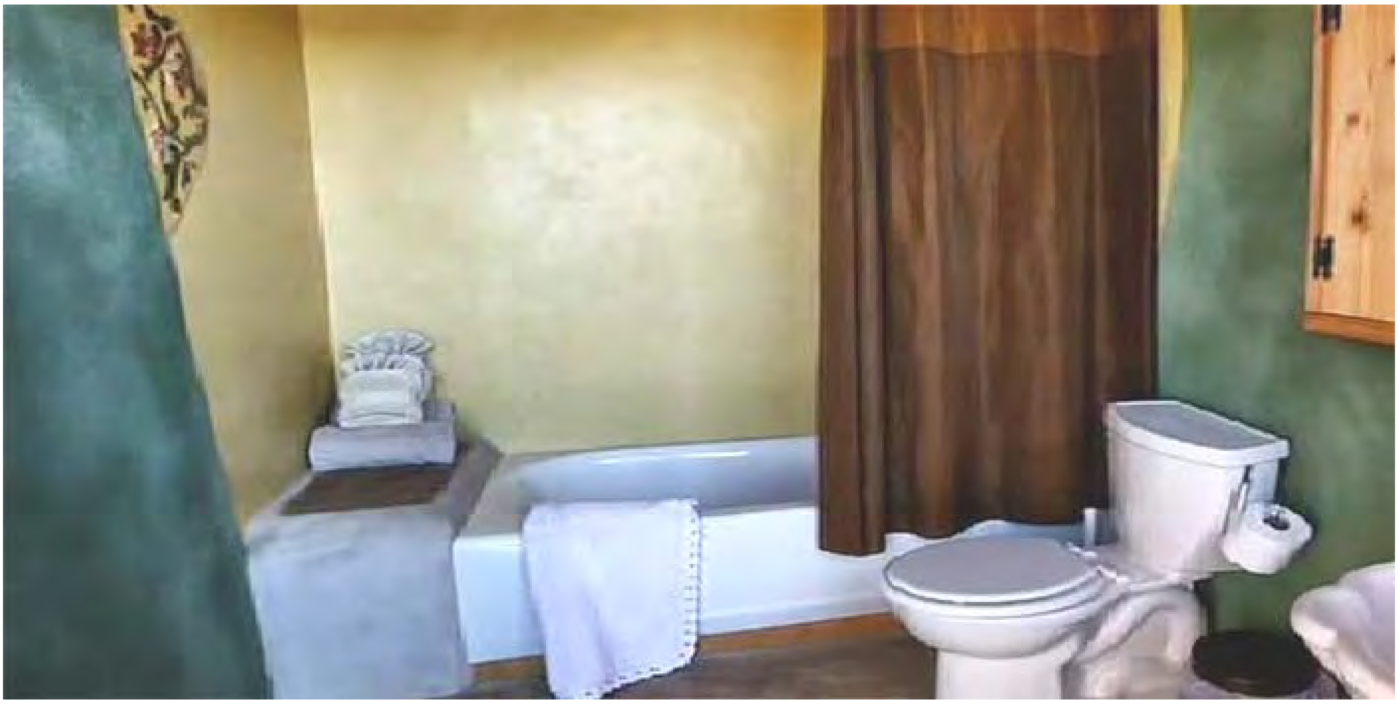
Steel bars called "rebar" are driven into the walls and positioned to the exact height, and a reinforced concrete ring is cast around the top of the walls to give overall strength to the structure, before the heavy tree trunks are put into place.

A nice feature of this style of construction is using coloured glass bottles in walls to allow light through and allow artistic designs to give the impression of stained glass.

When the wall is finished off and the bottles polished, the effect is really good, especially since the glass bottles are effectively free being recycle materials. However, choosing them as part of your living room is a matter of personal taste:



It is quite normal to have conventional styles of construction:



The important thing to remember about this house is that the walls are thick and so have a high thermal mass. The 'greenhouse' section all along the South side of the main building forms a heat buffer and water filtration. The roof is seriously effective with a one-inch thick layer of timber with tarred paper covering it, and then eight-inches of polystyrene on top of that and a ridged metal roof on top of that. That is a seriously effective thermal layer. This style of construction is definitely worth considering.

Chapter 15: You Are Being Deceived

Without your knowledge, you were stolen from your parents at birth and automatically became the judicial property of a commercial company pretending to be your government. What you think of as "your" birth certificate is **proof** of this action. The biggest secret is that your government is a collection of commercial companies whose only real purpose is to take as much money from ordinary people as they can, using unlawful actions. Their sole intention is to keep you poor, in fear and doing whatever they tell you to do.

The Situation in the UK

This is a large subject, so let's take it step by step and start with people who were born in the UK. I will discuss the position of a typical native of what is called "The United Kingdom of Great Britain and Northern Ireland". The average person living in this area believes that he is a free person living in a democracy which is governed by elected parliamentary representatives of the people, protected by legal statutes introduced by Parliament and enforced by police officers who are there to ensure your protection where physically possible. Those who are better informed, believe that the Magna Carta signed in 1215 affords them substantial rights and freedoms.

None of that is true. Not a single item.

The inhabitants of this region fall into two categories which are "landowners" and "everyone else". The term "landowner" is, of course, ridiculous. No human can own land. The only way that you can own something is if you create it from materials which you own, if it is given to you as a gift by the rightful owner, or if you buy it from the rightful owner.

If I state "I own the whole of the planet Mars" it does not give me any genuine ownership of the planet. What has happened on planet Earth is that an individual stakes out an area and says "This is my land, I own it, and I will kill anyone who says that I don't". That can certainly frighten most people away from the area, but it does **not** give the squatter genuine ownership of the land. Consequently, no human owns any land whatsoever, and it is not possible for any land to be bought as there is no previous human owner of the land in question.

Killing a squatter on the land and claiming ownership of that land by right of conquest is farcical. It is true that violent bully-boys take control of areas of land through intimidation and peaceful people dare not oppose them. No human has any more rights than any other human, but violence and the threat of violence have been used to create a notional group of people called "landowners". Is it right? Is it just? No, of course not, but it is what has happened.

This violent situation resulted in there being two groups of humans in the country. The violent "landowners" called "Knights", "Lords", "Barons" or some other irrelevant title, who join together to maintain what they have taken, and then there are the other people who have been intimidated by them, sometimes called "serfs", whom the landowners feel free to rob on a regular basis through sheer intimidation.

Already, there was a certain degree of deception being practiced by the landowners as they said to the serfs "we will protect you, and in return, you can work for us and pay us to protect you. This, of course, was a complete con, because if it wasn't for the landowners, there would be no need at all for "protection" from other landowners. And, oh yes, the protection required the serfs to put their lives on the line as part of the "protection" racket.

There was one group of landowners who operated more by trickery than by sheer force of arms. Going under the general title of the "Church" their influence came from telling people that when they die that they would not go to "heaven" if they were not servants of the Church. That technique worked very well and even influenced the head honcho of the landowners - the Monarch who was the ultimate "landowner". Don't get me wrong. I'm not saying that it is wrong to worship God, follow a moral code, live an upright and blameless life, **but**, doing that has nothing whatsoever to do with being subject to any human or human organisation.

A point which you have probably missed is that the 'landowners' considered the serfs to be sub-human "things" and not people at all. Unfit to, and incapable of, owning land under any circumstances. Considered to be 'goods and chattels' owned by the landowners. At that time, "serf" was an alternative word for "slave".

It is not possible for one human to genuinely "own" another human. Parents do not own the children born to them. They have a duty and a responsibility to nurture them and care for them and ideally, love them, but they do not own them. The weird notion which landowners have that they "own" humans is as false as anything can get. Slavery is another act of violence. Only a very ill-informed person believes that slavery has been 'abolished' as it is more widespread today than at any other time in all of recorded history, and it has nothing whatsoever to do with skin colour.

In the well-known year of 1066, another violent 'landowner' arrived in England and by force of arms, imposed Roman law on all of England. You will recall that Rome was very heavily into slaves and the slaves had no rights or privileges, no possessions and no protection, in spite of the fact that in reality, every one of them actually had equal entitlement to the rights claimed by their so-called "owners", both slaves and masters being human beings. So, please understand clearly, that Roman law encompassed the notion of people being called slaves, and owned as "things".

In 1213, King John was excommunicated and that frightened him so much that he signed a contract with the Pope. The contract is known as the "Treaty of Verona" and it undertook to introduce Rome's canon law to England, which made Archbishop Stephan Langton, the effective ruler of all of the country. The contract was supposed to give the Pope ownership of all of the lands, people, animals, etc. of all of King John's kingdom. According to this contract, the Vatican owns all of England and all of the British Commonwealth countries.

This is, of course, a rubbish document. Firstly, King John did not genuinely own any land of any description and never could have. Secondly, King John did not and never could have owned any of the people living on that land. Thirdly, a contract cannot be signed on behalf of a third party, so his signature could never, ever have any genuine effect on the people of the land. If that were not the case, then I could sign a contract on your behalf, guaranteeing that you would pay me a million pounds. It couldn't happen and if it did, it would be meaningless. The Treaty of Verona contract only applies to the signing parties, to have any effect on the people of the land would require them to be fully informed of the consequences and give their consent to the contract, and that never happened.

In an attempt to be cunning, the treaty was worded so as to make it appear to apply to the direct descendants of both the English monarch and the direct descendents of the Pope, namely, his successors. Personally, that seems highly doubtful to me as that would make it, in effect, a contract between people who have not agreed to it or signed it, and it is by no means obvious how a contract could be binding on people who are not party to it and who have not signed it.

However, just two years later in 1215 the landowners forced King John to sign a contract called the "Magna Carta". It is highly doubtful that a contract where one of the parties is intimidated into signing, has any actual validity, but that aside, the contract was made under the conditions prevailing at that time. The landowners, called “Barons” or “Free men” in the document, were insisting on a continuing agreement between them and the monarch. The contract has nothing to do with the serfs who were considered “things” with no rights at all. Today, members of the general public, who are actually the descendants of those serfs, read the Magna Carta and not understanding the situation when it was written, mistakenly think that it speaks of them. It doesn’t. The objective was actually an attempt to strengthen the Treaty of Verona.

This power-play continued in 1600 when a private company was set up. It is still in place today and it is called “The Ministry of Justice” D-U-N-S Number 22-549-8526, Directors: Lord Falconer of Thoroton. Today, all Magistrate Courts are private for-profit companies subsidiaries of this main commercial company and not, as most believe, part of the government of the UK.

The next step came in 1689 with the “Bill of Rights” whose purpose was to make the monarch subject to Parliament. Again, this was introduced with the intention of ensuring that no monarch could set aside the Treaty of Verona and deny the Pope (supposed) ownership of the British empire and all the people in it. The Bill of Rights settled the succession of the crown, creating a Dynasty which has been maintained right up to now. The only powers of a Constitutional Sovereign created by this “Bill of Rights” is to warn, to guide and to be informed, just that and nothing else. In 1701 there was the Act of Settlement to confirm the line of royal succession.

In 1694 a privately owned company called “**The Bank of England**” was formed. The name gives the impression that it is a government organisation, but that is not the case. Actually, the UK has no government but instead there is a set of interlocking, privately owned, for-profit commercial companies designed to give the false impression of a government. For example, **the House of Commons** is a commercial for-profit company (number UC2279443). **The Labour Party** is a commercial company which trades under the name of “Allister Darling MP”.
The House of Lords which is the highest court in the land is a private company.

Then there is the **United Kingdom Corporation Ltd.**, formerly known as the “United Kingdom plc”. In passing, anyone who has a National Insurance Number, is automatically deemed to be an employee of the United Kingdom Corporation Ltd. The Company policy of that corporation requires each employee, to pay tax and follow all the legislative rules (“statutes”) of that corporation. Anyone who breaks the rules of the corporation will be disciplined under the legislation of that corporation.

The police forces of the United Kingdom Corporation are all companies which can be seen from their company registrations, and their job is to enforce the rules of the Corporation. **Every court** in the land is a company. There is a commercial company called the “**Secretary of State for Trade and Industry**”, which ceased trading on 4th November 2002 and yet it still operates TV licensing, taking £3 billion per year through it’s subsidiary commercial private limited company called “Consignia (Customer Management) Ltd.”, which is part of it’s group of 35 subsidiary companies.

This continues to a ridiculous level where the company called “**The Devon and Cornwall Police**” has been taken over by a company called SouthWestOne which is one of a group of companies whose Ultimate Parent Company is IBM, but this Police Constabulary is a public service paid for by the taxpayer and given an annual budget of £256,800,000 taken from members of the public. Isn’t IBM a lucky company to be given £256,800,000 per year to help it run it’s business at a profit !

Equally ridiculous is the **Lancashire County Council** which was incorporated as a company (IP00666C) in 2002. It’s registered office was 3rd Floor, Christ Church Precinct, County Hall, Preston. It was completely dissolved on 25th January 2008 and all of it’s Assets and Liabilities were transferred on 12th November 2007 to another company - “The Blues and Twos Credit Union Ltd.” whose registered address is Lancashire Police Headquarters, PO Box 77, Hutton, Preston.

If you feel that these things are all straightforward and aboveboard, then I would like you to change a bundle of £3 notes for me, and as well, perhaps you would be interested in buying the Eiffel Tower.

The ordinary people resident in the UK are descended from the slaves called “serfs” and the only protection which they have is the “Common Law”, upheld by a policeman or a policewoman, each of whom receive authority through, and only through, their personal oath of allegiance to the monarch and the monarch’s oath to uphold Common Law. The Police Authority for whom the policeman or policewoman work, actually has no authority itself as, being a company, it cannot swear an oath. Policemen and policewomen have a duty to uphold Common Law and to protect and serve members of the public.

UK Common Law deals with a human causing death or injury to another human, damage to property or acting fraudulently in dealings with others. It is based mainly on the earlier findings of courts and is modified from time to time if it is found to be unjust. Surprisingly, the main corrections are supposed to come, not from judges, but from juries. A jury is the most powerful element in any court of law for they have the power to dismiss a case and even to go against the law. A jury has “discretion” and they can order the judge to find against the law if they believe that in the particular case which they are trying, the law would be unfair, so they adjudicate on both the individual case **and** on the underlying law. Judges do not always bring this to the attention of jurors.

A system has been set up by the Law Society with the express intention of enslaving members of the general public. They have taken words from the English language and redefined them to create another language called “Legalese”.

The translation for this language back into English is given in the publication “Black’s Law Dictionary”. The average member of the UK public is generally unaware that Legalese is being spoken and that what sounds like a simple, innocuous question in English, is actually a highly-loaded and underhand attempt to cause him both distress and unwarranted financial loss.

The objective of a lawyer is to make money for his commercial company and particularly for himself. To help them, lawyers have set up a system of "statutes" which are supposed to have the force of law, but which, being crafted by their sister parliamentary commercial companies, are **not** the law. These things are "statutes" and they don't actually apply to humans. Being wholly invented "legal" devices, they only apply to other "legal" things, which are essentially, just pieces of paper. Since a piece of paper does not own any money or goods, to get any real financial gain from their actions, they need to trick a human into taking on responsibility for a piece of paper. If they succeed in this, then they can demand money from that piece of paper and get the unfortunate human to actually provide the money even though the fictitious legal charges do not apply to that human.

Meet Your Strawman

In order to do this, they have to persuade the human to enter into a contract with them, agreeing to pay them money, essentially, for nothing in return. Their main trick is creating a fictitious legal identity using the name of the human. This is done by creating a "Birth Certificate" in the same name. Most parents mistakenly believe that they **have** to register the birth of their child, which is actually **not** a requirement under the law (which **does** apply to humans, as opposed to "statutes" which don't apply to humans).

In spite of their mistake, the fictitious legal "person" produced by creating the Birth Certificate document, the human who has the same first and last names as those recorded on the birth certificate, has no actual link to that document unless he can be tricked into agreeing to be linked to it.

All of the company statutes such as Income tax, Council tax, television licence, parking tickets, and the like are not being charged against a human but instead are being charged against the legal fiction with nearly the same name, sometimes called a "strawman". If the human refuses to agree that there is a link, then the invented charges collapse and the human is left alone until the next attempt to fool him. At this time there is a very nicely produced video http://www.youtube.com/watch?v=ME7K6P7hlko which explains the fiction of the strawman legal document.

The people who work for one of the commercial companies called Police Forces have two entirely different roles. As a police**man** or police**woman** they have a duty under common law to protect members of the public, and serve them by upholding common law. They have an entirely different role as a police **officer** dedicated to making money for their employer by imposing all kinds of fines, charges and penalties under a series of statutes invented by their sister companies. These financial penalties do not actually apply to humans, and so trickery must be employed in order to con the human into undertaking to pay when there is no requirement for the human to do so.

A Police **Officer** is a corporate employee who acts as a Revenue Collector for the Corporation and enforces Acts of Parliament.

A Police **Community Support Officer** is a Corporate employee who has no powers whatsoever, and holds no Oath of Office. They are given a Warrant Card and told to keep it because while they don't need it now, they will need it at some point in the future. Without an oath to the monarch, they have no authority at all.

The British people live in a "common law jurisdiction". This means that no Civil Law Statute applies to them at any point **unless the individual consents to it.** If asked to give your name, do not do so as that is a trick which places you into the realm of civil law which does not apply to you at all unless you consent to be placed under it. You are not obliged under common law to answer the question which asks your name and/or address. The police officer will be following training and may well not be aware that trickery is involved, never having been trained in common law and their duties under it, to each member of the public.

The Comments of John Harris

John Harris of the http://www.tpuc.org/ web site makes the following points:

The deception of "Joinder" or more aptly named "pretensive joinder": The human is asked for his full name, address and date of birth in order to establish the LEGAL PERSONALITY, the address of the LEGAL PERSONALITY and the date on which the LEGAL PERSONALITY was created. Once Joinder has been established, they can then offer that LEGAL PERSONALITY a contract. But, they need the consent of the human to act on behalf of the fictitious LEGAL PERSONALITY and so the human is asked "do you UNDERSTAND?" The human is then required to sign at least one piece of paper saying that he is the LEGAL PERSONALITY and that as the LEGAL PERSONALITY, he UNDERSTANDS.

This is deception as "UNDERSTAND" is taken to mean "STAND UNDER" and has nothing to do with the human comprehending anything. During any process where a human has any dealing with Corporation Officers, he is asked "do you understand?" and that is simply about **consent**. He is being asked to represent the LEGAL PERSONALITY and give the Corporate Officer authority over him.

The deception of "Notice": In Legalese, a "notice" is not a bill or a demand, instead, it is an offer of contract. When the offer has been made, the LEGAL PERSONALITY must be established through Joinder because the LEGAL PERSONALITY is only a piece of paper. Consequently, the human has to agree to represent that piece of paper by saying "I understand". Fixed penalty notices are the same as all, and any, statements made: they are simply, self-perpetuating Contracts. Making a statement to police is exactly the same - a self-perpetuating contract.

The deception of "Includes": The Inclusion of one is the Exclusion of another – this is a maxim (an established, unchallengeable fact). A summons (invitation) for watching TV without a licence has "We will present any evidence found of your watching TV without a licence, which may include a statement taken under caution by one of our Enforcement Officers". But the legalese "may" translates into "must", but if you make a statement with your name, address and confirmation of watching TV, then the court issues summary judgement as you have already incriminated yourself and the court has nothing to decide.

The deception of "Summons": Summons is synonymous with "invitation" which is a choice. They are inviting a LEGAL PERSONALITY to a Corporate place of business. The LEGAL PERSONALITY is just a piece of paper, a BIRTH CERTIFICATE created by the United Kingdom Corporation and it is **not** the human. You can't be forced into a contract, so they have to deceive you into entering into one without realising what you are doing. They are using deception as every Magistrates Court is a trading name of the commercial company called "The Ministry of Justice" D-U-N-S Number 22-549-8526 which does not have a Parent Company listed meaning that it is a Parent Company. Directors: Lord Falconer of Thoroton, date of incorporation 1600. Legal people on being shown this registration, responded by saying that if this information is genuine (which it is), then the UK has been lawless for more than 400 years because the whole Justice System is being dealt with by a company.

Deception of the Name: If you go to a Court (which is a Corporate place of Business) as the Accused, you will be asked to confirm your Name, quoting the full name shown on your birth certificate, which is the LEGAL PERSONALITY. Titles such as Mr, Dr, Lord, PC, QC, or whatever are not asked for as they are not required. The "Accused" is actually the LEGAL PERSONALITY which is the name on the birth certificate, so when they ask for the person's NAME, they are talking to the LEGAL PERSONALITY and **not** the human. This is because a human **cannot** exist in the legal world - only pieces of paper can, and that is something which they are very careful not to tell you.

This is a really key issue. Natural Law and Common Law are the only laws which apply to humans and they deal only with harming other people or causing them loss, and outside of those restrictions, a human has free and unlimited entitlement to do anything he chooses which complies with these principles. As opposed to this, Acts of Parliament, “Statutes” and Statutory Instruments “Contracts” do not apply to the human but only to the piece of paper which is the LEGAL PERSONALITY and which has no reality. As the legal fiction of the LEGAL PERSONALITY was created by the company called “the United Kingdom Corporation”, it is that company which gets to say what the rights and duties are for that piece of paper.

The deception of the Birth Certificate: When a person is born in Britain, the mother and father submit a Birth Certificate Registration Form, which is a piece of paper. There is no requirement under common law to do this. When any limited company or corporation is set up, there is always a Certificate of Registration in order to create it’s LEGAL PERSONALITY and that is a piece of paper. Please note that a British Birth Certificate states quite clearly that it is **not** evidence of identity, that is, it has nothing to do with a human. Marked on it is “Crown Copyright” showing clearly that it does not belong to an individual and was created by “the crown” which is not the monarch but is the independent 'City of London' represented by the Law Society and acting on behalf of the private owners. This act of Registering a child, makes that child a “ward of the court” which means that the child can be taken away from the parents at any time.

The deception of Registration: If I lawfully own a vehicle, then it cannot be taken away from me and crushed as that would constitute a criminal act and considered theft, no matter who takes it. However, if I Register my vehicle, then, without realising it, I hand ownership of the vehicle over to the registering company as a free gift. They acknowledge the gift by issuing me with a piece of paper stating that I am “the Registered Keeper” of their vehicle, to which they assign a number in their registration records of the vehicles which they own (although they will not pay for the upkeep of their vehicles).

John also asks:

Do you believe Parliament is elected to Represent the people and their wishes? It isn’t, they are Directors of a commercial ‘for-profit’ corporation and so, nothing will ever change.

Do you believe in Politics? There is no such thing.

Do you believe that the only way to sort the UK out is to elect a different Political Party? It makes no difference as all you are doing is choosing employees of a commercial company, and the owners dictate what the company does, no matter who the corporate serving officers may be.

Do you believe that Acts of Parliament (“Statutes”) are Law? They aren’t.

Do you believe that Statutory Instruments are Law? They aren’t.

What The UK Police Can, and Can’t Do

Posted September 26th, 2008 by Guy_Euden

Do you feel intimidated when pulled over? Do you feel intimidated when stopped in the street?

Do you feel that you are obliged to give them information or answer their questions? If your answer is “yes” to any of these questions, then you **don't** know your rights. A police officer is not what he was many moons ago. In bygone days they cared for their employers (yes you), they actually wanted to help you, they wanted to solve crimes, they had compassion, a sense of fair play and in response to this they earned our respect and admiration.

ALL of that has changed! Police officers are now Revenue Agents plain and simple and if any police officer is silly enough to think that's not true, or just wish to profess it isn't, then let him try not giving out fixed penalties for a month and see if a talking to is not the result! The truth is that they are now your adversary and that is not meant in a violent way, more like a game of who can get who to do as they’re told, and they are trained to get from you what they need in order to actually fine or arrest you by actually getting you to consent to it. Let’s quickly look at all laws that don't include Death or Injury to others, Damage to another's property or using fraud in your contracts.

OK, these three very heavy crimes are all you can truly be guilty of - YES it’s all you can truly be guilty of!!! Anything else is just STATUTE LAW and the simple to remember definition of this law is “laws that only apply if you consent to them”!! Here, look at the definition of a Statute: "Legislative rule of society given the force of law **by the consent of the governed**". Yes look at the last four words, "CONSENT OF THE GOVERNED" that is you!! So, if you don't consent, then they can’t do anything. Yes, I know what you’re thinking, but it really **is** that simple. Ok, an officer walks up to you and says "can I ask you some questions?" Don't consent. Ask him "what is the nature of the intended detention?". Record the conversation and let him see that you are doing this. Use your mobile, as 99% of mobile phones available today have recorders so go for it! If he says that you cannot record this conversation, then what he is in fact saying is, “yep you guessed it - I don't consent to be recorded!!”. So, you simply say "Ok, am I free to go?"

The simple fact is that they **need** your consent, and they have some very cool tools to use to get it, one is intimidation, and another is acting. They act like they are your friend. They act like they care. They just ACT! This is to put you off guard and most people sing like canaries!! Their other weapon of choice is Inconvenience. You don't have time to waste playing their game, so you talk in order to get away quicker, and wham! - they have their result! If you are pulled over for an offence under an act, for example, speeding, seatbelt or some other infraction, it is all part of the "Road Traffic Act of 1988 keyword is "ACT" and believe you me what a merry old act it is, it is pure stage play.

When issuing a ticket they **need** your name so SHUT UP! Don't argue with them as that is “adversarial” so just SHUT UP! They need your name and date of birth to confirm which corporation they are going to give the bill of exchange to (bills of exchange defences are simple but we are not doing those right now). So don’t provide a name, or date of birth, or address. Don't give them anything to work with, don't say a single word no matter what coercion they try, hell they might even go for some "good cop bad cop" stuff this is great to watch when you are fully aware of their lack of power, it's like watching "EastEnders". If they read you your rights you have to say that you understand in order for handcuffs to be put on you. **Again, your consent is necessary** (get it?) don't say a word!!

Now these Officers of Revenue don't like the grim realisation that they have no power. You could get arrested, yes I am afraid that they can still arrest you, but the worst that they can do is keep you for a few hours, so get some sleep, oh and if you have a “notarised claim of right, with a schedule of charges for arrest and detention”, then sleep even sweeter because these fools are paying you to learn that they have no power! I know that getting arrested isn't nice, they know this, that's why its one of their tools to get you **to consent to their unnecessary and unlawful penalties**.

But if you don't stay quiet, then they will always have power over you. Now if they are going to arrest you, one nice way of them playing into your hands is if you say these few of words:

"Officer, I am a peaceful man, there will be no violence, but you are obliged to note that if you are going to arrest me it will be under protest and duress at all times and I reserve all of my rights at all times, and I waive none of those rights at any time for any cause or reason". If they take you to the station remember DON'T SAY A SINGLE WORD. Hell you might get a new name! "JOHN DOE". If they try to fingerprint you, tell them that you do **not** consent to this. If they try to get your DNA then tell them that you do **not** consent to this. If they touch you, tell them, "Officer I do not consent to be touched at all".

If you make it known that you know your rights then they will leave you alone. Trust me, they will only act illegally if you continue to let them do so. Remember that any "legal" acts that they choose to quote are powerless, a clawless, toothless tiger.... they have no power if you don't consent.

Summary:

The present UK (and world) situation is designed to confuse you. The UK is a "Common Law jurisdiction" which has had a spurious and fake "legal" system added on to it in order to rob you blind. The average inhabitant of the UK is bound to keep the common law or suffer the consequences. The common law requires a human not to kill or injure another human, not to damage or steal his property and not to swindle him.

The spurious "legal" system introduced by the Law Society (who consider all other humans as inferiors), is designed to steal from those humans by deception and fraud. It operates by tricking humans into inadvertently and unknowingly entering into a contract to pay money to someone who will not provide anything of worth in exchange.

This is done by using the legalese language which has taken words from the English language and changed their meanings without making the changes of meaning made clear to the public. This covert and surreptitious method is used to get a human to represent a legal fiction which is a piece of paper and undertake to pay invented debts attached to that piece of paper.

The average UK resident believes that there is a UK government, when in fact, there is no actual government, just a commercial company pretending to be a government, namely, the company called "The United Kingdom Corporation Limited". People are fooled into "voting" for the election of corporate officers in this company in order to make them believe that there actually is a government where no government exists.

This hateful "legal" system is there solely to enslave and rob ordinary people living in the UK and there appears to be no way to circumvent it. I have seen a calculation which estimates that on average, ordinary people in the UK have 80% of their income taken from them in taxes. So, for every £100 they earn, they only receive £20.

A self-employed person may be able to avoid paying Income Tax, Council Tax, TV licence and some other minor taxes. An employed person is tied to a "legal entity" employer which cannot escape the legal snare and so is forced to take Income Tax, National Insurance and Child Support amounts off a person's earned payment before the remainder is given to the employee.

Unfortunately, even self-employed people can't escape the thieves because they add their massive charge on to essential items which are not sold to people by name. For example, I have been told that 85% of the cost of a gallon of fuel for a vehicle is tax. That means that if I buy £100 of fuel, it really should have only cost me £15 as that is the cost of finding it, extracting it, refining it, transporting it and making a profit on selling it. My £85 has been taken against my will, by people who are not entitled to it.

If I buy almost anything in a shop, then 17.5% of the selling price is taken from me and given to someone who doesn't deserve it. In reality, it is much more than that because the item purchased was transported to the shop using fuel which was heavily taxed, and I have to pay that tax indirectly in the raised cost of the item. Also, the shop has to have heating and lighting, both of which are powered by heavily taxed fuel, which raises the price which I have to pay on the item. Then, there is the tax on the company and the tax on the company for having employees, both of which have to be covered in the price which I am charged. You can see why the person who worked out how much is really paid in tax, came up with an overall figure of 80% of a person's earned income. Even a self-employed person can't escape paying a major amount of indirect tax. The often-quoted phrase "we live in a free country" does not seem to have any basis in fact. So, how about "the land of the brave and the land of the free" across the Atlantic ocean, do they fare any better?

The Situation in America

In 1606, King James I the King of England set up a commercial enterprise called "The Virginia Company" with himself as the main stockholder. The Virginia Company was formed in anticipation of the imminent influx of white Europeans, mostly British at first, into the North American continent. The Virginia Company of London (also called the "London Company") was chartered by King James with the object of colonising the eastern coast of North America between latitudes 34^{o}N and 41^{o}N. It's shareholders were Londoners. The Virginia Company claimed ownership of most of the land that we now call America. The Virginia Company (the British Crown and the bloodline families) claimed rights to 50% of all gold and silver mined, plus percentages of other minerals and raw materials, and 5% of all profits from other ventures.

As has been already remarked, no human can own land as there is no way that genuine title to the land can be bestowed on any human, short of God giving him a written deed of ownership as a gift. No human can buy land from another human or organisation as they didn't genuinely own the land in the first place. King James was essentially, no different from any other man and he had no justification for blithely claiming ownership of another country. Even being the first squatter on the land (which he wasn't) does not give any man ownership of that land. Consequently, his was, and is, a spurious claim with no basis in fact or any form of justification.

At this time, America does not have a government because "The UNITED STATES" is a commercial company. The term "United States" means a Federal corporation. The US President is the President of a commercial corporation and American citizens are, in effect, the employees of that Corporation. This present situation was sneaked in by the covert actions of the Americans who organised and ran the civil war with the intention of taking lands and assets from people who lived in the South. Most people imagine that, say, Virginia, is a part of the American nation under the American government. However, this is not true as every one of the "States" is actually set up as a commercial, for-profit, company, under the parent company "The United States of America". So the reality is that instead of being a State of the Nation, the "State of Virginia" is the name of a commercial for-profit company.

The Vatican claims that it owns Britain and all of the commonwealth countries. Britain claims that it owns America as a British colony. The King of England provided financial backing to both sides of the Revolutionary war and believed that the lands of the Virginia Company were granted (on lease) to the colonies under a Deed of Trust and therefore they could not claim ownership of the land. They could pass on the perpetual use of the land to their heirs or sell the perpetual use, but they could never own the land itself as ownership was supposedly retained by the British Crown.

You may be interested to know that the Vatican's system of law is based on the ancient Roman system and in Rome, the seat of power for Caesar was called "Capitol Hill" where Caesar would meet with 'the Senate'. The Pope believes that he can abolish any law in the United States (Elements of Ecclesiastical Law Vol. 1, 53-54). The Pope's laws are supposed to be obligatory on everyone.

The conglomeration of privately owned commercial corporations know as “the United Sates of America” go along with the same old ridiculous scam of considering American human beings to be “slaves” under Roman law. Consequently, no American can own property because slaves can’t own property. If an American reads the Deed to a property which he thinks that he owns, he will discover that he is listed as a “Tenant” (Senate Document 43, 73rd Congress, 1st Session).

After the first 21 years from the formation of the Virginia Company, all ‘duties, imposts and excises’ paid on trading activities in the colonies were paid directly to the British Crown through the Crown treasurer. Queen Elizabeth II of Britain, controls and has amended U.S. Social Security: Statutory Instrument 1997 No. 1778 The Social Security (United States of America) Order 1997.

The American Inland Revenue Service Publication 6209 is form 1040 which is to be used for tribute paid to Britain. Americans are considered to be slaves to the Queen and own absolutely nothing (Senate Document 43). America’s Social Security is not insurance or a contract, nor is there a Trust Fund. The criminal courts on the lands of the Virginia Company were to be operated under Admiralty Law, the law of the sea, and the civil courts under common law, the law of the land. This is a crucial point. The United States of America is not a country, it is a corporation owned by the same Brotherhood bloodlines who owned the Virginia Company, because the USA is considered to be the property of the Virginia Company.

There is a “USA” which is the 68 square miles of land west of the Potomac River on which is built the federal capital, Washington DC and the District of Columbia, also the US protectorates of Guam and Puerto Rico. And then there is a “usA” the “united states of America” which are the lands of the various states. These lands are still supposedly owned by the British Crown as the head of the Virginia Company.

The Act of 1871 created a new, altered Constitution. The title was changed to capital letters and the word “for” was changed to the word “of”. That is, “The Constitution for the united states of America” was altered to “THE CONSTITUTION OF THE UNITED STATES OF AMERICA”.

An American cannot use the Constitution to defend himself because he is not a party to it. “The People” does not include ordinary U.S. Citizens. The Act of 1871 also created a separate form of government for the District of Columbia, which is a ten mile square parcel of land which is governed with British Admiralty law, U.C.C. (Acts of the Forty-First Congress, Section 34, Session III, chapters 61 and 62).

When Americans agree to have a Social Security Number, they surrender their sovereignty and agree to become franchisees of the United States (which is supposedly the Virginia Company of the British Crown). Americans are led to believe that there is only one United States and that the Federal government is the rightful government. The use of lower/upper-case characters is making a legal statement. If you are American, then you should notice that when you receive any correspondence relating to government, law or anything to do with finance or taxation that your name is always spelt entirely in block capitals.

Your name in block capitals is not you. It is a corporation set up by the ‘government’ Corporation through the treasury department at the time of your birth. Any time that a child is born, a corporation/trust is created using his or her name in block capitals. One definition of “a human being” is “a corporation treated as having the rights and obligations of a person” while the definition of a “natural person” is ‘a real human being’, as distinguished from a corporation, which is often treated at law as being a fictitious person.

Everything in the “United States” is “For Sale”: roads, bridges, schools, hospitals, water, prisons, airports, etc. (Executive Order 12803). Americans are Human capital (Executive Order 13037).

The Emergency Banking Relief Act of 9th March 1933, defined the American people as legally, the **enemy** of the United States Government and the private, international Federal Reserve System became the Government of the United States.

The national flag of the United States always has a gold fringe when displayed in court or federal buildings, federally-funded schools and the uniforms of US troops. Under the International Law of the Flags, a gold fringe indicates the jurisdiction of commercial law, also known as British Maritime Law, and in the US as the uniform Commercial Code or "UCC".

George Bush launched a 'war on terrorism' on behalf of a private Corporation, to further the goals of that Corporation. It had nothing to do with 'America' or 'Americans', because those are very different legal entities. The United States Corporation owns the United States military and everything else that comes under the term 'federal'. It is not the duty of the US police to protect Americans. Their job is to protect the Corporation and arrest code breakers (Sapp v. Tallahassee, 348 So. 2nd. 363, etc.). There are no Judicial courts in America and there have not been since 1789. Judges do not enforce Statutes and Codes but instead, Executive Administrators enforce Statutes and Codes. The most powerful court in America is not the United States Supreme Court but instead, it is the Supreme Court of Pennsylvania (42 Pa.C.S.A. 502). Pennsylvania is the keystone state.

The FCC, CIA, FBI, NASA and all similar organisations were never part of the United States government, even though the "US Government" held shares of stock in the various Agencies. (U.S. v Strang, 254 US 451, Lewis v US, 680 F.2d, 1239).

Americans may think that their government and legal system is pegged in some way to the Constitution, but it is not. The United States, like Britain and elsewhere, is ruled by commercial law to overcome the checks and balances of common law. It is a monumental fraud.

The web site http://www.youtube.com/watch?v=klwWcp9eiPw&feature=player_embedded lists what it considers to be a series of little-known facts about America. It says:

"The IRS is not a U.S. government agency. It is an agency of the IMF which in turn is an agency of the United Nations. The United States has **not** had a Treasury since 1921 as the U.S. Treasury is now the IMF. The United States does not have any employees because there no longer is a United States. The FCC, CIA, FBI, NASA, etc. were never part of the U.S. government but are privately owned companies. US Social Security numbers are issued by the UN through the IMF, (the SS5 form does not state who issues it). There have been no Judicial Courts in America since 1789. There have been no Judges in America since 1789. According to GATT, Americans must have a Social Security Number. New York City is defined in the Federal regulations as the United Nations. Social Security is not insurance or a contract and Social Security cheques come directly from the IMF which is an agency of the UN.

All Americans are slaves and so can own absolutely nothing, not even what they think of as being their own children. The most powerful court in America is the Supreme Court of Pennsylvania. The King of England financially backed both sides of the Revolutionary War. Americans can't use the US Constitution to defend themselves because they are not a party to it. Britain is owned by the Vatican and the Pope claims to own the entire planet through the laws of conquest and discovery (Papal Bulls of 1495 and 1493). The Pope has ordered the genocide and enslavement of millions of people (Papal Bulls of 1455 and 1493). The Pope's laws are obligatory on all Americans. "The People" does not include ordinary Americans. (Barron v City Council of Baltimore 32 US 243)".

When you become aware of these things, it becomes easier to understand why voting in a Presidential election can never make any difference - after all, he is only the President of a commercial company whose corporate policy is set by the owners of the company and not by the President. It also explains what these commercial companies have done and are still doing through their agencies such as the CIA.

The fractional reserve policy perpetrated by the Federal Reserve, which has spread in practice to the great majority of banks in the world, is, in fact, a system of modern slavery. Think about it: money is created out of debt. What do people do when they earn debt? They submit to employment to pay it off. But if money can only be created out of loans, how can society ever be debt-free? It can't, and that's the point. And it is the fear of losing assets coupled with the struggle to keep up with the perpetual debt and inflation in the system, compounded by the inescapable scarcity in the money supply itself, created by the interest which can never be repaid, that keeps the wage-slave in line, powering the pyramid which benefits only the elite at the top of the pyramid. At the end of the day, for whom are you really working? The banks. Money is created in a bank and inevitably ends up in a bank. They are the true masters along with the corporations and governments which they support. Physical slavery requires people to be housed and fed, economic slavery requires people to house and feed themselves.

Michael Rivero has put together a concise statement on the situation in America, and his statement is at http://whatreallyhappened.com/WRHARTICLES/allwarsarebankerwars.php where he says:

I know that many people have a great deal of difficulty with understanding just how many wars are started for no other purpose than to force private central banks on to nations, so let me share a few examples, in order that that you can understand why the US Government is engaged in so many wars against so many foreign nations. There is ample precedent for this.

The United States fought the war of the American Revolution primarily over King George III's Currency Act, which forced the colonists to conduct their business only using printed bank notes borrowed from the Bank of England at interest. After the revolution, the new United States adopted a radically different economic system in which the government issued its own value-based money, so that private banks like the Bank of England were not siphoning off the wealth of the people through interest-bearing bank notes.

"The refusal of King George 3rd to allow the colonies to operate an honest money system, which freed the ordinary man from the clutches of the money manipulators, was probably the prime cause of the revolution". -- Benjamin Franklin, Founding Father

But bankers are nothing if not dedicated to their schemes to acquire your wealth, and they know how easy it is to corrupt the leaders of a nation. Just one year after Mayer Amschel Rothschild had uttered his infamous statement: *"Let me issue and control a nation's money and I care not who makes the laws"*, the bankers succeeded in setting up a new Private Central Bank called the First Bank of the United States, largely through the efforts of the Rothschild's chief US supporter, Alexander Hamilton.

Founded in 1791, by the end of its twenty year charter the First Bank of the United States had almost ruined the nation's economy, while enriching the bankers. Congress refused to renew the charter and signalled their intention to go back to a state-issued value-based currency on which the people paid no interest at all to any banker. This resulted in a threat from Nathan Mayer Rothschild against the US Government: "Either the application for renewal of the charter is granted, or the United States will find itself involved in a most disastrous war". Congress still refused to renew the charter for the First Bank of the United States, whereupon Nathan Mayer Rothschild railed, "Teach those impudent Americans a lesson! Bring them back to colonial status!"

Financed by the Rothschild-controlled Bank of England, Britain then launched the war of 1812 to re-colonise the United States and force them back into the slavery of the Bank of England, or to plunge the United States into so much debt they would be forced to accept a new private central bank. The plan worked. Even though the War of 1812 was won by the United States, Congress was forced to grant a new charter for yet another private bank issuing the public currency as loans at interest, and that was the Second Bank of the United States. Once again, private bankers were in control of the nation's money supply and cared not who made the laws or how many British and American soldiers had to die for it.

Once again the nation was plunged into debt, unemployment, and poverty through the plundering of the private central bank, and in 1832 Andrew Jackson successfully campaigned for his second term as President under the slogan, "Jackson And No Bank!" True to his word, Jackson succeeds in blocking the renewal of the charter for the Second Bank of the United States.

"Gentlemen! I too have been a close observer of the doings of the Bank of the United States. I have had men watching you for a long time, and am convinced that you have used the funds of the bank to speculate in the breadstuffs of the country. When you won, you divided the profits amongst you, and when you lost, you charged it to the bank. You tell me that if I take the deposits from the bank and annul its charter I shall ruin ten thousand families. That may be true, gentlemen, but that is your sin! If I let you go on, you will ruin fifty thousand families, and that would be my sin! You are a den of vipers and thieves. I have determined to rout you out, and by the Eternal, (bringing his fist down on the table) I will rout you out!" -- Andrew Jackson, shortly before ending the charter of the Second Bank of the United States. From the original minutes of the Philadelphia committee of citizens sent to meet with President Jackson (February 1834), according to Andrew Jackson and the Bank of the United States (1928) by Stan V. Henkels

Shortly after President Jackson (the only American President to actually pay off the National Debt) ended the Second Bank of the United States, there was an attempted assassination which failed when both pistols used by the assassin, Richard Lawrence, failed to fire. Lawrence later said that with Jackson dead, "Money would be more plenty".

Of course, the present day American public school system is as subservient to the bankers' wishes to keep certain items of history from you, just as the corporate media is subservient to Monsanto's wishes to keep the dangers of Genetically Modified foodstuffs from you, and the Global Warming cult's wishes to conceal from you the fact that the Earth has actually been cooling for the last 16 years. Thus is should come as little surprise, that much of the real reasons for the events of the Civil War are not well known to the average American.

When the Confederacy seceded from the United States, the bankers once again saw the opportunity for a rich harvest of debt, and offered to fund Lincoln's efforts to bring the south back into the union, but at 30% interest. Lincoln remarked that he would not free the black man by enslaving the white man to the bankers and using his authority as President, he issued a new government currency, the “greenback”. This was a direct threat to the wealth and power of the central bankers, who responded quickly.

"If this mischievous financial policy, which has its origin in North America, becomes entrenched, then that Government will issue it’s own money without cost. It will pay off debts and be without debt. It will have all the money necessary to carry on it’s commerce. It will become prosperous to a degree which is without precedent in the history of the world. The brains, and wealth of all countries will migrate to North America. That country must be destroyed or it will destroy every monarchy on the globe". -- The London Times responding to Lincoln's decision to issue government Greenbacks to finance the Civil War, rather than agree to private banker's loans at 30% interest.

In 1872 New York bankers sent a letter to every bank in the United States, urging them to fund any newspapers which opposed government-issued money (Lincoln's greenbacks): *"Dear Sir: It is advisable to do all in your power to sustain such prominent daily and weekly newspapers... as will oppose the issuing of greenback paper money, and that you also withhold patronage or favours from all applicants who are not willing to oppose the Government issue of money. Let the Government issue the coin and the banks issue the paper money of the country...To restore to circulation the Government issue of money, will be to provide the people with money, and will* *therefore seriously affect your individual profit as bankers and lenders".* -- Triumphant plutocracy; the story of American public life from 1870 to 1920, by Lynn Wheeler

"It will not do to allow the greenback, as it is called, to circulate as money any length of time, as we cannot control that". -- Triumphant plutocracy; the story of American public life from 1870 to 1920, by Lynn Wheeler

"Slavery is likely to be abolished by the war, power, and chattel slavery destroyed. This, I and my European friends are in favour of, for slavery is but the owning of labour and carries with it the care for the labourer, while the European plan, led on by England, is for capital to control labour by controlling the wages. THIS CAN BE DONE BY CONTROLLING THE MONEY". -- Triumphant plutocracy; the story of American public life from 1870 to 1920, by Lynn Wheeler

Goaded by the private bankers, much of Europe supported the Confederacy against the Union, with the expectation that victory over Lincoln would mean the end of the Greenback. France and Britain considered an outright attack on the United States to aid the confederacy, but were held at bay by Russia, which had just ended the serfdom system and had a state central bank similar to the system the United States had been founded on. Left free of European intervention, the Union won the war, and Lincoln announced his intention to go on issuing greenbacks. Following Lincoln's assassination, the Greenbacks were pulled from circulation and the American people forced to go back to an economy based on bank notes borrowed at interest from the private bankers.

Finally, in 1913, the Private Central Bankers of Europe, in particular the Rothschilds of Great Britain and the Warburgs of Germany, met with their American financial collaborators on Jekyll Island, Georgia to form a new banking cartel with the express purpose of forming the Third Bank of the United States, with the aim of placing complete control of the United States money supply once again under the control of private bankers. Owing to hostility over the previous banks, the name was changed to "The Federal Reserve" system in order to grant the new bank a quasi-governmental image, but in fact it is a privately owned bank, no more "Federal" than Federal Express. Indeed, in 2012, the Federal Reserve successfully rebuffed a Freedom of Information Lawsuit by Bloomberg News on the grounds that as a private banking corporation and not actually a part of the government, the Freedom of Information Act did not apply to the operations of the Federal Reserve. The year 1913 proved to be a transformative year for the nation's economy, first with the passage of the 16th "income tax" Amendment and the false claim that it had been ratified.

“I think that if you were to go back and try to find and review the ratification of the 16th Amendment, which was the internal revenue, the income tax, I think that if you went back and examined that carefully, you would find that a sufficient number of States never ratified that Amendment”. – U.S. District Court Judge James C. Fox (Sullivan vs United States, 2003).

Later in 1913, apparently unwilling to risk another questionable amendment, Congress passed the Federal Reserve Act over the Christmas holiday, while members of Congress who were opposed to the measure were at home. This was a very underhanded deal, as the Constitution which explicitly grants Congress the authority to issue the public currency, does not authorise it to delegate that authority, and so it should have required a new Amendment to allow Congress to transfer that authority to a private bank. But Congress did pass it, and President Woodrow Wilson signed it (as he had promised the bankers that he would, in exchange for generous campaign contributions). Wilson later regretted that decision, stating: *“I am a most unhappy man. I have unwittingly ruined my country. A great industrial nation is now controlled by its system of credit. We are no longer a government by free opinion, no longer a government by conviction and vote of the majority, but a government by the opinion and duress of a small group of dominant men”.* – Woodrow Wilson 1919.

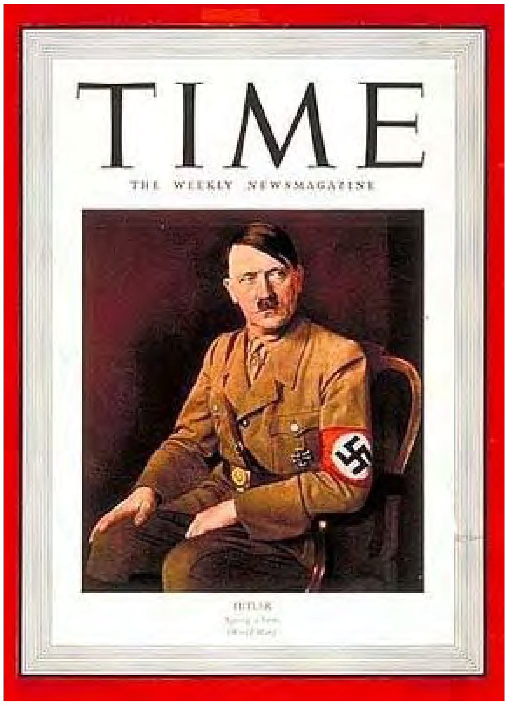
The next year, World War One started, and it is important to remember that prior to the creation of the Federal Reserve, there was no such thing as a world war.

The First World War started between Austria-Hungary and Serbia, but quickly shifted to focus to Germany, whose industrial capacity was seen as an economic threat to Great Britain, who saw the decline of the British Pound as a result of too much emphasis on financial activity to the neglect of agriculture, industrial development, and infrastructure (not unlike the present day United States).

Although pre-war Germany had a private central bank, that bank was heavily restricted, and inflation kept to reasonable levels. Under government control, investment was guaranteed to internal economic development, and Germany was seen as a major power. So, in the media of the day, Germany was portrayed as the prime instigator of World War One, and subsequently, not just defeated, but had its industrial base flattened.

Following the Treaty of Versailles, Germany was ordered to pay the war costs of all of the participating nations, even though Germany had not actually started the war. This amounted to three times the value of all of Germany itself. Germany's private central bank, to whom Germany had gone deeply into debt to pay the costs of the war, broke free of government control, and massive inflation followed (mostly triggered by currency speculators), permanently trapping the German people in endless debt.

When the Weimar Republic collapsed economically, it opened the door for the National Socialists to take power. Their first financial move was to issue their own state currency which was not borrowed from private central bankers. Freed from having to pay interest on the money in circulation, Germany blossomed and quickly began to rebuild its industry. The media called it "The German Miracle". TIME magazine lionized Hitler for the amazing improvement in life for the German people and the explosion of German industry, and even named him TIME Magazine's “Man Of The Year” in 1938.



Once again, Germany's industrial output became a threat to Great Britain, resulting in these comments:

"Should Germany merchandise (do business) again in the next 50 years, we have led this war (WW1) in vain". **- Winston Churchill in The Times (1919)**

"We will force this war upon Hitler, if he wants it or not". **- Winston Churchill (1936 broadcast**)

"Germany becomes too powerful. We have to crush it". **- Winston Churchill** (November 1936 speaking to US - General Robert E. Wood).

"This war is an English war and its goal is the destruction of Germany". **- Winston Churchill (-Autumn 1939 broadcast) .**

Germany's state-issued value-based currency was also a direct threat to the wealth and power of the private central banks, and as early as 1933 they started to organise a global boycott against Germany to strangle this upstart ruler who thought he could break free of private central bankers!

JUDEA DECLARES WAR ON GERMANY

Jews Of All The World Unite In Action

BOYCOTT OF GERMAN GOODS

MASS DEMONSTRATIONS IN MANY DISTRICTS

DRAMATIC ACTION

"Daily Express" Special Political Correspondent.

ALL Israel is uniting in wrath against the Nazi onslaught on the Jews in Germany.

Adolf Hitler, swept into power by an appeal to elemental patriotism, is making history of a kind he least expected. Thinking to unite only the German nation to race consciousness he has roused the whole Jewish people to a national renaissance.

The appearance of the swastika symbol of a new Germany has called forth the Lion of Judah, the old battle symbol of Jewish defiance.

Fourteen million Jews dispersed throughout the world have banded together as one man to declare war on the German persecutors of their co-religionists. Sectional differences and antagonisms have been submerged in one common aim—to stand by the 600,000 Jews of Germany who are terrorised by Hitlerist anti-semitism, and to compel Fascist Germany to end its campaign of violence and suppression directed against its Jewish minority.

World Jewry has made up its mind not to rest quiescent in face of this revival of medieval Jew-baiting.

... appealing for an end of the Hitler "terror."

Every Rabbi in the City of New York has been placed under a sacred obligation by Rabbinical decree to devote Saturday's sermon to the plight of the Jews in Germany.

The "New York Times" this morning says a list of a thousand German immigrants who have come to the United States during recent years has been compiled by an extreme Nazi organisation, the object being to use these people for Nazi propaganda in the United States.

SPECIAL SESSION

The organisation of Jewish youth in Britain is organising demonstrations in London and the provinces during the week-end.

The Board of Deputies of British Jews, representing the entire Jewish community in Great Britain, is meeting in special session on Sunday to discuss the German situation and decide on what action is to be taken to counteract the attacks on their German fellow Jews.

OFFICER'S DAYS OF LOVE

HIGHER WAGES FOR STEEL WORKERS

AN INCREASE OF THREE SHILLINGS A WEEK

BRIGHT SPOT IN A BLACK TOWN

THE "Daily Express" has sent a special representative on an unusual mission. He is touring the north in search of high wages. In his tour he is going to tell the facts about all classes of wages, high and low. He is going to show how low wages reduce the morale of the community. He is going to show how courageous spending reacts favourably throughout the community.

In his first dispatch it is revealed that the steel masters of Middlesbrough have been able to make a gesture in the cause of high wages.

Fitters in steel works have recently received an increase of 3s. a week. Their wages are not high, but this is a step in the right direction. It is a bright spot in an otherwise black town—brought low by wage cuts and false economy.

CUTS THAT KILL

New "Sweep" Bill In The Dail

MR. DE VALERA AND STATE CONTROL

SECRET MEASURE

"Daily Express" Special Correspondent.

DUBLIN, Thursday.

WHILE Mr. Jack O'Sheehan, the official announcer of the Irish sweepstake draw, was dividing the remnants of the latest Irish lottery prize fund between lucky ticket-holders in the Plaza Ballroom to-day I was listening to an Under-Secretary of the Free State Government introducing a Bill which may change the whole future, scope, and purpose of these Irish hospitals lotteries.

NO CLUE

A mysterious measure entitled "The Public Hospitals Bill, 1933," appeared on the agenda for this afternoon's meeting of the Dail.

The Bill was set down for formal introduction, and a motion to this effect was moved in a six or seven-words speech by Mr. Sean O'Kelly, the Minister of Local Government.

His brief remarks gave no clue to the

MR. MacDONALD EXPLAINS HIS TOUR

"PEACE CAN BE KEPT IN EUROPE"

MR. RAMSAY MACDONALD faced a crowded House of Commons yesterday afternoon when he spoke about his visits to Paris, Geneva, and Rome, and his talks with Signor Mussolini.

The German, French, Italian, Polish, and Belgian Ambassadors were among a crowd of diplomatic representatives in their special gallery, and Mr. Bruce, of Australia, and other representatives of the Dominions also listened.

Mr. MacDonald, who was greeted with cheers, said:—

"I take the earliest available opportunity to inform the House regarding what happened while the Foreign Secretary and myself were at Geneva and Rome.

Mr. MacDonald.

"Therefore, the Foreign Secretary and I went to Geneva. Our first business was to discover how matters exactly stood, and for that purpose we interviewed for some two or three days the leading delegates from various nations.

LATE NEWS

LABOUR LEADER BEREAVED

Broadcasting Programmes on Page Fifteen.

As had been the case in World War One, Great Britain and other nations threatened by Germany's economic power looked for an excuse to go to war, and as public anger in Germany grew over the boycott, Hitler foolishly gave them that excuse. Years later, in a spirit of candour, the real reasons for that war were made clear:

"The war wasn't only about abolishing fascism, but to conquer sales markets. We could have, if we had intended to, prevented this war from breaking out without firing one shot, but we didn't want to". **- Winston Churchill to Truman (Fultun, USA March 1946).**

"Germany's unforgivable crime before WW2 was its attempt to loosen its economy out of the

world trade system and to build up an independent exchange system from which the world-finance couldn't profit any more. ...We butchered the wrong pig". **- Winston Churchill (The Second World War - Bern, 1960).**

As a side note, we need to step back before WW2 and recall Marine Major General Smedley Butler. In 1933, Wall Street bankers and financiers had bankrolled the successful coups by both Hitler and Mussolini. Brown Brothers Harriman in New York was financing Hitler right up to the day war was declared with Germany. And they decided that a fascist dictatorship in the United States based on the one on Italy would be far better for their business interests than Roosevelt's "New Deal" which threatened massive wealth re-distribution to recapitalise the working and middle class of America. So the Wall Street tycoons recruited General Butler to lead the overthrow of the US Government and install a "Secretary of General Affairs" who would be answerable to Wall Street and not the people, would crush social unrest and shut down all labour unions.

General Butler pretended to go along with the scheme but then exposed the plot to Congress. Congress, then as now in the pocket of the Wall Street bankers, refused to act. When Roosevelt learned of the planned coup he demanded the arrest of the plotters, but the plotters simply reminded Roosevelt that if any one of them were sent to prison, their friends on Wall Street would deliberately collapse the still-fragile economy and blame Roosevelt for it. Roosevelt was thus unable to act until the start of WW2, at which time he prosecuted many of the plotters under the Trading With The Enemy Act. The Congressional minutes into the coup were finally released in 1967 and became the inspiration for the movie, "Seven Days in May" but with the true financial villains erased from the script.

"I spent 33 years and four months in active military service as a member of our country's most agile military force -- the Marine Corps. I served in all commissioned ranks from second lieutenant to Major General. During that period I spent more of my time being a high-class muscle man for Big Business, for Wall Street and for the bankers. In short, I was a racketeer, a gangster for capitalism. I suspected that I was just a part of a racket at the time. Now I am sure of it. Like all members of the military profession I never had an original thought until I left the service. My mental faculties remained in suspended animation while I obeyed the orders of the higher-ups. This is typical with everyone in the military service. Thus I helped make Mexico and especially Tampico safe for American oil interests in 1914. I helped make Haiti and Cuba a decent place for the National City Bank boys to collect revenues in. I helped in the raping of half a dozen Central American republics for the benefit of Wall Street. The record of racketeering is long. I helped purify Nicaragua for the international banking house of Brown Brothers in 1909-12. I brought light to the Dominican Republic for American sugar interests in 1916. In China in 1927 I helped see to it that Standard Oil went on its way unmolested. During those years, I had, as the boys in the back room would say, a swell racket. I was rewarded with honours, medals and promotion. Looking back on it, I feel I might have given Al Capone a few hints. The best he could do was to operate his racket in three city districts. I operated on three continents". -- General Smedley Butler, former US Marine Corps Commandant,1935

As President, John F. Kennedy understood the predatory nature of private central banking, he understood why Andrew Jackson fought so hard to end the Second Bank of the United States. So Kennedy wrote and signed Executive Order 11110 which ordered the US Treasury to issue a new public currency, the United States Note.

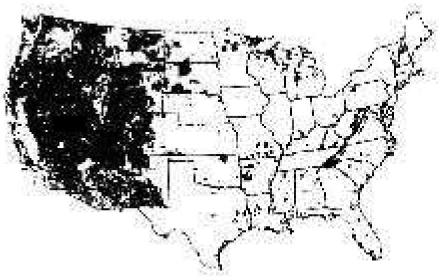
UNITED STATES NOTE
THE UNITED STATES OF AMERICA
A 18278796 A
WASHINGTON, D.C.
THIS NOTE IS LEGAL TENDER FOR ALL DEBTS, PUBLIC AND PRIVATE
A 18278796 A
FIVE DOLLARS

Kennedy's United States Notes were not borrowed form the Federal Reserve but created by the US Government and backed by the silver stockpiles held by the US Government. It represented a return to the system of economics on which the United States had been founded, and this was perfectly legal for Kennedy to do. All told, some four and a half billion dollars went into public circulation, eroding interest payments to the Federal Reserve and loosening their control over the nation. Five months later John F. Kennedy was assassinated in Dallas Texas, and the United States Notes pulled from circulation and destroyed (except for samples held by collectors). John J. McCloy, President of the Chase Manhattan Bank, and President of the World Bank, was named as part of the Warren Commission, presumably to make certain that the banking dimensions behind the assassination were concealed from the public.

As we enter the eleventh year of what future history will most certainly describe as World War Three, we need to examine the financial dimensions behind the wars. Towards the end of World War Two, when it became obvious that the allies were going to win and dictate the post war environment, the major world economic powers met at Bretton Woods, a luxury resort in New Hampshire in July 1944, and hammered out the Bretton Woods agreement for international finance. The British Pound lost its position as the global trade and reserve currency and its place was taken by the US dollar (part of the price demanded by Roosevelt in exchange for the US entry into the war). Without the economic advantages of being the world's central currency, Britain was forced to nationalise the Bank of England in 1946. The Bretton Woods agreement, was ratified in 1945, and in addition to making the US dollar the global reserve and trade currency, obliged the signatory nations to tie their currencies to the dollar. The nations which ratified Bretton Woods did so on two conditions. The first was that the Federal Reserve would refrain from over-printing the dollar as a means to loot real products and produce from other nations in exchange for ink and paper; basically an imperial tax. That assurance was backed up by the second requirement, which was that the US dollar would always be convertible to gold at $35 per ounce.

Of course, the Federal Reserve, being a private bank and not answerable to the US Government, did start overprinting paper dollars, and much of the perceived prosperity of the 1950s and 1960s was the result of foreign nations' obligations to accept the paper notes as being worth gold at the rate of $35 an ounce. Then in 1970, France looked at the huge pile of paper notes sitting in their vaults, for which real French products like wine and cheese had been traded, and notified the United States government that they would exercise their option under Bretton Woods to return the paper notes for gold at the $35 per ounce exchange rate. Of course, the United States had nowhere near the gold to redeem the paper notes, so on August 15th, 1971, Richard Nixon "temporarily" suspended the gold convertibility of the US Federal Reserve Notes.

This "Nixon shock" effectively ended Bretton Woods and many global currencies started to disengage from the US dollar. Worse still, since the United States had collateralised their loans with the nation's gold reserves, it quickly became apparent that the US Government did not in fact have enough gold to cover the outstanding debts. Foreign nations began to get very nervous about their loans to the US and understandably were reluctant to lend any additional money to the United States without some form of collateral. So Richard Nixon started the environmental movement, with the EPA and its various programs such as "wilderness zones", Road-less areas", Heritage rivers", "Wetlands", all of which took vast areas of public lands and made them off limits to the American people who were technically the owners of those lands. But Nixon had little concern for the environment and the real purpose of this land grab under the guise of the environment was to pledge those pristine lands and their vast mineral resources as collateral on the national debt. The plethora of different programs was simply to conceal the true scale of how much American land was being pledged to foreign lenders as collateral on the government's debts; eventually almost 25% of the nation itself.



With open lands for collateral already in short supply, the US Government embarked on a new program to shore up sagging international demand for the dollar. The United States approached the world's oil producing nations, mostly in the Middle East, and offered them a deal. In exchange for only selling their oil for dollars, the United States would guarantee the military safety of those oil-rich nations. The oil rich nations would agree to spend and invest their US paper dollars inside the United States, in particular in US Treasury Bonds, redeemable through future generations of US taxpayers. The concept was labelled the "petrodollar". In effect, the US, no longer able to back the dollar with gold, was now backing it with oil. Other peoples' oil, and the necessity to keep control over those oil nations in order to prop up the dollar has shaped America's foreign policy in the region ever since.

But as America's manufacturing and agriculture has declined, the oil producing nations faced a dilemma. Those piles of US Federal Reserve notes were not able to purchase much from the United States because the United States had little (other than real estate) which anyone wanted to buy. Europe's cars and aircraft were superior and less costly, while experiments with GMO food crops led to nations refusing to buy US food exports. Israel's constant belligerence against its neighbours caused them to wonder if the US could actually keep their end of the petrodollar arrangement. Oil-producing nations started to talk of selling their oil for whatever currency the purchasers chose to use. Iraq, already hostile to the United States following Desert Storm, demanded the right to sell their oil for Euros in 2000 and in 2002, the United Nations agreed to allow it under the "Oil for food" program instituted following Desert Storm. One year later the United States re-invaded Iraq, lynched Saddam Hussein, and placed Iraq's oil back on the world market only for US dollars.

Following 9-11, the clear US policy shift away from being an impartial broker of peace in the Middle East to one of unquestioned support for Israel's aggressions, only further eroded confidence in the Petrodollar deal and even more oil-producing nations started openly talking of oil trade for other global currencies.

Over in Libya, Muammar Gaddafi had instituted a state-owned central bank and a value-based trade currency, the Gold Dinar. Gaddafi announced that Libya's oil was for sale, but only for the Gold Dinar. Other African nations, seeing the rise of the Gold Dinar and the Euro, even as the US dollar continued its inflation-driven decline, flocked to the new Libyan currency for trade. This move had the potential to seriously undermine the global hegemony of the dollar. French

President Nicolas Sarkozy reportedly went so far as to call Libya a “threat” to the financial security of the world.

So, the United States invaded Libya, brutally murdered Gaddafi (the object lesson of Saddam's lynching not being enough of a message, apparently), imposed a private central bank, and returned Libya's oil output to dollars only. The gold that was to have been made into the Gold Dinars is, as of last report, unaccounted for.

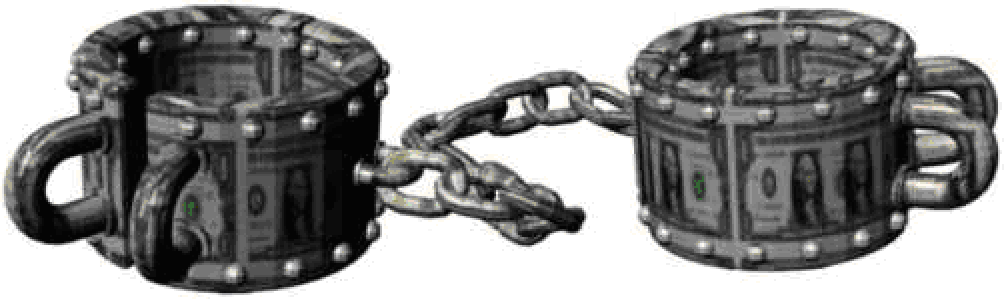
According to General Wesley Clark, the master plan for the "dollarification" of the world's oil nations included seven targets, Iraq, Syria, Lebanon, Libya, Somalia, Sudan, and Iran (Venezuela, which dared to sell their oil to China for the Yuan, is a late addition). What is notable about the original seven nations originally targeted by the US is that none of them are members of the Bank for International Settlements, the private central bankers private central bank, located in Switzerland. This meant that these nations were deciding for themselves how to run their nations' economies, rather than submit to the international private banks.

Now the gun sights of the bankers are on Iran, which dares to have a government central bank and sell their oil for whatever currency they choose. The war agenda is, as always, to force Iran's oil to be sold only for dollars and to force them to accept a privately owned central bank.

The German government recently asked for the return of some of their gold bullion from the Bank of France and the New York Federal Reserve. France has said it will take 5 years to return Germany's gold. The United States has said they will need 8 years to return Germany's gold. This suggests strongly that the Bank of France and the NY Federal Reserve have used the deposited gold for other purposes, and they are scrambling to find new gold to cover the shortfall and prevent a gold run. So it is inevitable that suddenly France invades Mali, ostensibly to combat Al Qaeda, with the US joining in. Mali just happens to be one of the world's largest gold producers with gold accounting for 80% of Mali exports. War for the bankers does not get more obvious than that!

Americans have been raised by a public school system and media that constantly assures them that the reasons for all these wars and assassinations are many and varied. The US claims to bring democracy to the conquered lands (they haven't; the usual result of a US overthrow is the imposition of a dictatorship, such as the 1953 CIA overthrow of Iran's democratically elected government of Mohammad Mosaddegh and the imposition of the Shah, or the 1973 CIA overthrow of Chile's democratically elected government of President Salvador Allende, and the imposition of Agusto Pinochet), or to save a people from a cruel oppressor, revenge for 9-11, or that tired worn-out catch all excuse for invasion: “weapons of mass destruction”. Assassinations are always passed off as "crazed lone nuts" to obscure the real agenda.

The real agenda is simple. It is enslavement of the people by the creation of a false sense of obligation. That obligation is false because the Private Central Banking system, by design, always creates more debt than money with which to pay that debt. Private Central Banking is not science, it is a religion; a set of arbitrary rules created to benefit the priesthood, meaning the owners of the Private Central Bank. The fraud persists, with often lethal results, because the people are tricked into believing that this is the way life is supposed to be and no alternative exists or should be dreamt of. The same was true of two earlier systems of enslavement, ‘Rule by Divine Right’ and ‘Slavery’, both of which are systems designed to trick people into obedience, and both of which are now recognised by modern civilization as illegitimate. Now we are entering a time in human history where we will recognise that ‘rule by debt’, or rule by Private Central Bankers issuing the public currency as a loan at interest, is equally illegitimate. It only works as long as people allow themselves to believe that this is the way life is supposed to be.



But understand this above all else, Private Central Banks do not exist to serve the people, the community, or the nation. Private Central Banks exist to serve their owners, to make them rich beyond the dreams of Midas and all for the cost of ink, paper, and the right bribe to the right official.

Behind all these wars, all these assassinations, the hundred million horrible deaths from all the wars lies a single policy of dictatorship. The private central bankers allow rulers to rule only on the condition that the people of a nation remain enslaved to the private central banks. Failing that, any ruler will be killed, and their nation invaded by those other nations which are already enslaved to private central banks.

The so-called "clash of civilizations" we read about on the corporate media is really a war between banking systems, with the private central bankers forcing themselves on to the rest of the world, no matter how many millions must die for it. Indeed the constant hatemongering against Muslims lies in a simple fact. Like the ancient Christians (prior to the Knights Templar's private banking system), Muslims forbid usury (the lending of money at interest), and that is the reason why the American government and media insist that Muslims must be killed or converted. They refuse to submit to currencies issued at interest. They refuse to be debt slaves. So off to war American children must go, to spill their blood for the gold of the money-junkies. We barely survived the last two world wars. In the nuclear/bio weapon age, are the private central bankers willing to risk incinerating the whole planet just to feed their greed? Apparently so.

Flag waving and propaganda aside, all modern wars are wars by and for the private bankers, fought and bled for by third parties unaware of the true reason why they are expected to be killed and crippled. The process is quite simple. As soon as the Private Central Bank issues its currency as a loan at interest, the public is forced deeper and deeper into debt. When the people are reluctant to borrow any more, that is when the Keynesian economists demand the government borrow more to keep the pyramid scheme working. When both the people and government refuse to borrow any more, that is when wars are started, to plunge everyone even deeper into debt to pay for the war, then after the war to borrow more to rebuild. When the war is over, the people have about the same as they did before the war, except the graveyards are far larger and everyone is in debt to the private bankers for the next century. This is why Brown Brothers Harriman in New York was funding the rise of Adolf Hitler.

As long as Private Central Banks are allowed to exist, inevitably, as night follows day, there will be poverty, hopelessness, and millions of deaths in endless World Wars, until the Earth itself is sacrificed in flames to Mammon. The path to true peace on Earth lies in the abolishment of all private central banking everywhere, and a return to the state-issued value-based currencies that allow nations and people to become prosperous.

Michael Rivero

The Economic Hit-Men

It is one of the most ingenious scams for social manipulation ever invented, and at it's core, it is an invisible war waged against the population, and you will remember that the Emergency Banking Relief Act of 9th March 1933, **defined** the American people as "the **enemy"** of the United States Government. Debt is the weapon used to conquer and enslave societies and interest is its prime ammunition. While the majority of people are not aware of this reality, banks in collusion with governments and corporations continue to expand and perfect their tactics of economic warfare, spawning new bases such as the World Bank and the International Monetary Fund and introducing a new kind of soldier - the economic hit-man.

Here is the testimony of one of those American economic hit-men, John Perkins:

We, the economic hit men, are the ones really responsible for creating the first really global empire, and we work many different ways. Perhaps the most common is that we will identify a country which has resources which our corporations covet, such as oil, and then arrange a huge loan to that country from the World Bank or one of it's sister organisations. But the money never actually goes to the country, instead, it goes to our big construction corporations to build infrastructure projects in that country, like industrial power plants, things which benefit a few rich people in that country (in addition to our corporations), but really don't help the people involved, however those people and the whole country are left holding a huge debt so big that they can't repay it, which is the whole plan - that they can't repay it. So we economic hit men go back to them and say "listen, you owe us a lot of money, you can't repay it, so sell your oil real cheap to our oil companies, allow us to build a military base in your country or send troops to some place in the world to support our troops in somewhere like Iraq, or vote with us in the UN to have their electric utility company privatised, or their sewage system privatised and sold to US corporations or other multinational corporations, so there is a whole mushrooming thing and it's the way that the World Bank and the International Monetary Fund operate to put a whole country in debt with such a big debt that it can't pay it, so you then offer to refinance that debt and get them to pay even more interest and you demand this 'quid pro quo' or 'conditionality' or 'good governance' which means basically that they have to sell off their resources, including their social services and utility companies, their school systems sometimes, their penal systems, their insurance systems to foreign corporations. So, it's a double, triple, quadruple whammy.

Examples:

Iran 1953: The precedent for economic hit men began back in the early 1950s when the democratically elected Prime Minister of Iran, Dr Mohammed Mossadegh, was considered to be a hope for democracy - Time Magazine's Man of the Year. One of the policies which he ran on was the idea that the oil companies needed to pay the Iranian people a lot more for the oil which they were taking out of Iran. We didn't like that, of course, but we were afraid to do what we would normally do, which is to send in the military. Instead, we sent in one CIA agent, a relative of President Roosevelt. He went in with a few million dollars and was very efficient and effective and in a short amount of time he managed to get Mossadegh overthrown and brought in the Shah of Iran to replace him. It was extremely effective. So back here in the United States, people in Washington looked around and said "wow - that was easy and cheap !" So this established the whole new way of manipulating countries and creating empire. The only problem with Roosevelt was that he was a card-carrying CIA agent and if he had been caught, the ramifications would have been pretty serious. So, very quickly at that point a decision was made to use private 'consultants', to channel the money through the World Bank, the IMF or one of the other such agencies, bring in people like me who worked for private companies, so that if we got caught, there would be no government ramifications.

Guatemala 1954: When Arbenz (Jacobo Arbenz Guzman) became President of Guatemala, the country was very much under the thumb of the United Fruit Company, the big international corporation and Guzman ran under the strategy of giving the land back to the people. When he was elected he started implementing those policies of giving the land back to the people. United

Fruit didn't like that so much, so they hired a Public Relations company in the United States mounted a huge campaign to convince the people of the US, the press of the US and the Congress of the US that Arbenz was a Soviet puppet and if we allowed him to stay in power the Soviets would have a foothold in this hemisphere, which, at that time, was a huge fear on everybody's minds, so to make a long story short, out of this public relations campaign came a commitment on the part of the CIA and the military to take this man out, and in fact, we did. We sent in planes, we sent in soldiers, we sent in jackals, we sent in everything to take him out, and we did take him out. And as soon as he was removed, his successor reinstated the links to the big corporations including United Fruit.

Ecuador 1981: Ecuador for many, many years was ruled by pro-US dictators, often relatively brutal. Then it was decided that they were going to have a truly democratic election Jaime Roldos (Aguilera) ran for office and his main goal, he said, as President was to make sure that Ecuador's resources were used to help the people. And he won, overwhelmingly, by more votes than anyone has ever won anything in Ecuador and he began to implement these policies to make sure that the profits from oil went to help the people. Well, we didn't like that in the United States. I was sent down as one of several economic hit men to change Roldos, to corrupt him, to bring him around, to let him know "you know, you and your family can get very rich if you play our game but if you but if you continue to try and keep these policies you promised, then you are going to go". He wouldn't listen. He was assassinated "Ecuadorian Leader Dies in Plane Crash". As soon as the plane crashed, the whole area was cordoned off. The only people allowed in were the US military from a nearby base and some of the Ecuadorian military. When an investigation was launched, two of the key witnesses died in car accidents before they had a chance to testify. A lot of very, very strange things went on around the assassination of Roldos. I, like most of the people who really looked at this case had absolutely no doubt that it was an assassination and of course, in my position of an economic hit man, I was expecting something to happen to Jaime, whether a coup or an assassination I was sure that he would be taken down as he was not being corrupted, he would not allow himself to be corrupted the way we wanted to corrupt him.

Panama 1981: Omar Tarrijas President of Panama was one of my favourite people. I really, really liked him, he was very charismatic and he really wanted to help his country. When I tried to bribe him, to corrupt him, he said “look, John, he called me Juanita, look Juanita, you know, I don’t need the money, what I really need is for my country to be treated fairly. I need the United States to replay the debts which you owe my people for all the destruction you have done here. I need to be in a position to help other Latin American countries with their independence and be free of this terrible presence from the North. You people are exploiting us so badly. I need to have the Panama Canal back in the hands of the Panamanian people. That’s what I want. So leave me alone, don’t try to bribe me”. It was in 1981 and in May Jaime Roldos was assassinated and Omar was very aware of this. He got his family together and said “I’m probably next, but it is ok because I’ve done what I came here to do, I’ve renegotiated the Canal, the Canal will now be in our hands”. He had been renegotiating the treaty with Jimmy Carter:

In June of that same year, just a couple of months later, he also went down in an aeroplane crash which there is no question was executed by CIA jackals. There is a tremendous amount of evidence, one of Tarrijas’ security guards handed him, at the last moment as he was getting on the plane, a small tape recorder which contained a bomb.

Venezuela 2002: It is interesting to me how this system has continued pretty much the same way for years and years and years except the economic hit men get better and better and better. Then we come up with, very recently, what happened in Venezuela in 1998 when (Hugo Rafael) Chavez gets elected, following a long line of Presidents who were very corrupt and who basically destroyed the economy of the country, and Chavez was elected following all of that. Chavez stood up to the United States demanding that Venezuela oil be used to help the Venezuelan people. Well we didn't like that in the United States, so in 2002, a coup was staged, and there is no question in my mind or in most other people's minds, that the CIA was behind that coup. The way that coup was fermented was very effective, like Colonel Roosevelt had done in Iran - paying people to go out into the streets to riot, to protest and say that Chavez is very unpopular. You know, if you can get a few thousand people to do that, television can make it look like the whole country and things start to mushroom, except in the case of Chavez, he was smart enough and the people were so strongly behind him that they overcame it, which was a phenomenal moment in the life of Latin America.

Iraq 2003: Iraq, actually, is a perfect example of the way the whole system works. We economic hit men are the first line of defence. We go in and try to corrupt governments and get them to accept these huge loans which we then use as leverage to basically own them. If we fail, as I failed in Panama with Omar Tarrijas, and in Ecuador with Jaime Roldos, men who refused to be corrupted, then the second line of defence is we send in the jackals and the jackals either overthrow governments or they assassinate and when that happens and a new government comes in, boy, it's going to toe the line as the new President knows what will happen if he doesn't. And in the case of Iraq, both of those things failed and the economic hit men were not able to get through to Saddam Hussein although they tried very hard. We tried very hard to get him to accept a deal but he wouldn't accept it and so the jackals went in to take him out but they couldn't do it as his security was very good. After all, he had at one time worked for the CIA and been hired to assassinate a former President of Iraq and failed, but he knew the system. So, in 1991 we send in the troops and we take out the Iraqi military, assuming that at that point that Saddam is going to come around. We could, of course, have taken him out at that time, but we didn't want to as he is the kind of strong man that we like, able to control his people and keep pumping oil for us. But when we took out his military he didn't come around so the economic hit men go back in the 90s without success. If they had had success, he'd still be running the country - we'd be selling him all the fighter jets he'd want, but they didn't have success. The jackals couldn't take him out again, so we sent the military in once again and took him out, and created for ourselves very lucrative reconstruction deals to rebuild a country which we had essentially destroyed - which is a very good deal if you own a construction company - a really big one. So, Iraq shows the three stages: the economic hit men - failed there, the jackals failed there, so as the final measure, the military goes in.

And in that way, we have really created an empire, but we have done it very, very subtly, it's clandestine. All the empires in the past were built by the military and everybody knew they were building them. The British knew they were building it, the French, the Germans, the Romans, the Greeks - they were all proud of it and they always had some excuse like "spreading civilisation", or spreading some religion, something like that, but they knew they were doing it. We don't. The majority of the people in the United States have no idea that we are living off the benefits of a clandestine empire, that today there is more slavery in the world than ever before.

You may have to ask yourself if it's an empire, then who's the Emperor? Obviously, our Presidents in the United States are not Emperors. An Emperor is someone who is not elected, does not serve a limited term, and who doesn't report to anyone. So you can't classify Presidents that way. But we do have what I consider to be the equivalent of the Emperor in what I call the "Corporatocracy". The Corporatocracy is this group of individuals who run our biggest corporations and they really act as the Emperor of this empire. They control our media (either by direct ownership or by advertising), they control most of our politicians because they finance their campaigns, either through corporations or through personal donations. They are not elected, they don't serve a limited term, they don't report to anybody, and at the very top of the Corporatocracy, we can't tell if the person is working for a corporation or for the government as they are always moving back and forth, so you get a guy who is one moment the president of a big company like Halliburton and the next moment he's the Vice President of the United States, or the President who is in the oil business and this is true whether you get Democrats or Republicans in the office, you have them moving back and forth through the revolving door, and in a way, our government is invisible a lot of the time as it's policies are carried out by a corporation on one level or another, and then again, the policies of the government are basically forged by the Corporatocracy and then presented to the government and become government policies. So, it is an incredibly cosy relationship. This isn't a "conspiracy theory" kind of thing, these people don't have to get together and plot to do things, they all basically work under one primary assumption, and that is that they must maximise profits regardless of the social and environmental costs.

This process of manipulation by the Corporatocracy, through the use of debt, bribery and political overthrow, is called "Globalisation". Just as the Federal Reserve keeps the American people in a position of indentured servitude, through perpetual debt, inflation and interest, the World Bank and International Monetary Fund fulfil this role on a global scale.

Oh, and by the way, the lame excuse for going to war with Iraq which was never believable beforehand, is laid out in fair detail here by a high-ranking US Major General expert in gathering and interpreting military and terrorist intelligence: http://www.youtube.com/watch?v=W0xzsbSbVUE&feature=player_embedded.

Libya 2011: If the ruler of a country refuses to become the servant of the New World Order people, he is subjected to character assassination and physically attacked with troops. I don't for a moment suggest that Col. Gaddafi was a saint, but as the Bible so aptly remarks, you can tell a man's character by the things which he does, so what did Col. Gaddafi do? Well, here is some information passed to me and I leave you to decide for yourself:

1. In Libya, electricity is free for all of it's citizens.

2. There is no interest on loans, banks in Libya are state-owned and loans are given to all its citizens at 0% interest which is requirement of Libyan law.

3. Owning a home is considered a human right in Libya – Gaddafi vowed that his parents would not get a house until everyone else in Libya had a home. Gaddafi's father has died while he, his wife and his mother were still living in a tent.

4. Education and medical treatments are free in Libya. Before Gaddafi only 25% of Libyans were literate. Today the figure is 83%.

5. If any Libyan wants to take up farming, he receives farming land, a farm house, equipment, seeds and livestock to kick- start their farms – all for free.

6. If Libyans cannot find the education or medical facilities they need in Libya, the government funds them to go abroad for it – not just free, but they get US $2,300 per month for accommodation and running a car.

7. If a Libyan buys a car, the government pays 50% of the price.

8. The price of petrol in Libya is US $0.14 per litre (in the UK, it is $2.17 per litre at this time, which is more than 15 times as much).

9. Libya has no external debt and its reserves amount to US $150 billion – now frozen globally.

10. If a Libyan is unable to get employment after graduation, the state pays the average salary of the profession as if he or she is employed, until employment is found.

11. A portion of Libyan oil sale revenues is credited directly to the bank accounts of all Libyan citizens.

12. 40 loaves of bread in Libya costs just US $0.15 (in the UK, it is 200 times more expensive).

13. 25% of Libyans have a university degree, while in the UK, Sir Clive Woodhead, former Chief

Inspector of Schools, has recently recommended that children should leave school at age 14 and become apprentices.

14. Col. Gaddafi carried out the world's largest irrigation project, known as the Great Man-Made River project, to make water readily available throughout his desert country.

So, I will leave it up to you to decide if the attacks on Libya and the killing of Col. Gaddafi was an honest action designed to make the world a safer and better place, or if those actions were motivated by some other agenda.

The Technique:

The lawyers and bankers have the objective of taking all of your money and keeping you permanently in debt to them. In the UK, the currency was "the pound sterling" and a £1 note was a promise certifying that there was literally a one pound weight of sterling silver held in storage to back the value of that note and save the person carrying around the actual pound weight of silver.

That link was broken, and nowadays, the £1 note (or in the US, the $1 note) has no actual value as it is no longer a promise that an amount of valuable metal is being held in storage in order to give that piece of paper it's value. In reality, these paper currency notes have no more value than the paper notes in the board game "Monopoly" and that value is only the value of the paper on which the notes are physically printed, which is, almost nothing at all.

Take the process in America as an example: The "government" decides that it needs some money, so it calls up the (privately owned) Federal Reserve Bank and requests, say, $10,000,000,000. The Federal Reserve Bank replies saying "Sure, we will buy $10 billion in government Bonds from you". So the "government" takes some pieces of paper, paints some official-looking designs on them and calls them "Treasury Bonds". Then it puts a value on them of $10 billion and sends them over to the Federal Reserve Bank. In turn, the people in the Federal Reserve Bank draw up a series of impressive looking pieces of paper themselves, only, this time, calling them Federal Reserve notes, also designated with a value of $10 billion. The Federal Reserve Bank then takes these notes and trades them for the Treasury Bonds. Once this trade is complete, the government then takes the $10 billion in Federal Reserve notes and deposits them in a bank account, and on doing this, the $10 billion becomes legal tender money, adding $10 billion to the US money supply. And there it is: $10 billion in new money has been created out of nothing and with no intrinsic value whatsoever. Of course, this example is a generalisation because in reality, this transaction would occur electronically, with no paper used at all. In fact, only 3% of the US money supply exists in physical currency and the other 97% exists in computers alone.

The same style of operation happens in the UK as well with the (privately owned) Bank of England, producing valueless 'currency'. The banks deliberately compound the problem by lending this valueless money to individual people as a loan or mortgage, knowing full well that there is not enough money in circulation to pay off the loan and the interest. If, for example, the loan is £1000 on a credit card, then the credit card company will want about £1200 back as they charge interest. But as they do that with all of the "money" fraudulently created (actually ten times the amount in America), there is physically not enough to allow the interest to be paid unless the economy of the country keeps on expanding rapidly. The objective here is to take physical goods and possessions away from the borrower when he finds himself unable to pay the amount asked for.

The total lack of value of present day currency was demonstrated when a mortgage loan repossession was challenged in court in America. For any commercial contract anywhere in the world to be valid, something of worth has to be put forward by both parties to that contract. When a bank "lends" it's worthless money as a mortgage, it has put forward nothing of value and so the mortgage contract is not valid in law.

In 1969, there was a Minnesota court case involving a man named Jerome Daly who was challenging the foreclosure of his home by the bank which provided the loan to purchase it. His argument was that the mortgage contract required both parties (himself and the bank) to put up a legitimate form of property for the exchange. In legal language, this is called a "consideration" from both parties. Mr Daly explained that the money was, in fact, not the property of the bank as it was created out of nothing as soon as the loan agreement was signed. In other words, the money didn't come out of the bank's existing assets as the bank simply invented it, consequently, the bank put up nothing of value of it's own, except for a theoretical liability on paper. As the court case progressed, the bank's President, Mr Morgan, took the stand and the judges memorandum records that the "Plaintiff admitted that it, in combination with the Federal Reserve Bank ... did create the entire $14,000 in money in credit upon it's own books by bookkeeping entry ... the money and credit first came into existence when they created it. Mr Morgan admitted that no United States Law or Statute existed which gave him the right to do this. A lawful consideration must exist and must be tendered to support the Note" ... The jury found that there was no lawful consideration, and on this finding, the court rejected the bank's application for foreclosure and Mr Daly kept his home.

The Consequences:

There does not seem to be much point in commenting on the situation in other countries around the world as you will find the same style of underhand operation in most of them. However, when you understand what is going on, it explains why it has been so difficult to get any free-energy device on to the market for sale to members of the public.

A really major strand of both income and control comes from access to energy. The average person wants energy for heating and cooling a home, running household equipment such as refrigeration, lighting, computing, etc. and for powering a vehicle, operating power tools, and so on. Under the present deceptive regime, we are told from an early age that we need to burn a fuel in order to get this power, and instead of doing it individually, it appears to be cheaper to buy the power from the local energy company.

The reality is that we live in a sea of energy which can supply our every need for ever and ever without the slightest need for burning any kind of fuel. Devices for tapping this energy have been produced by literally thousands of inventive people and yet, they are not for sale. Why do you think that is?

Well, one of the reasons is that inventors of these devices often feel that they should "protect" their invention by patenting it and so they make an application to a Patent Office. Unfortunately, the Patent Office is a commercial business owned by the same people who make massive amounts of money from selling you oil to burn and electricity to use. Because of that, they steal the best of these inventions, often by telling the inventor that his invention is "Of National Security Importance" and so he can't use it, sell it or even speak to other people about it, and if he did, he would be put in prison. That is, of course, an unlawful deception as the people telling him that have nothing whatsoever to do with anything National, except the use of the word in their company name. There certainly is no government around to make any kind of statement like that.

The wonderful people then use your money in unlimited amounts to develop these inventions as secret "black" projects and they have been doing this for at least a hundred years. People who have been employed in some of these projects report that they now have technology anything from 100 to 1,000 years in advance of what the public is told about. Almost everything shown in the fictional "Star Trek" series has already been produced covertly in real life. The internet has made it difficult to keep on hiding these advances, but they fight back by posting false information, contradicting people who present the real deal, and generally disrupting and flooding every useful forum with a combination of rubbish and inflammatory attacks on forum members.

A major strand of the attempt to suppress the truth is through universities and respected Engineering bodies and publications. This is done through financial pressure. To have a successful career, a university professor needs to have regular publication of research papers. For this, he needs researchers who are paid to do the research. This is done through grants from rich people and organisations. Those are the very people who will under no circumstances allow the publication of any research which demonstrates that free-energy exists and they make sure that no funding will ever be available for any such research.

If a scientist steps out of line and goes public with the facts, he is immediately attacked by all of his former colleagues who promptly say that what he says is “impossible” and “breaks the laws of physics”, neither of which are actually true. For example, in 2010, Rosemary Ainslie and her colleagues demonstrated under strict laboratory conditions that a pulsed heating element produces 17 times more heat output than could be produced by the tiny electrical input driving the element. This was written up in standard scientific paper format and passed to the Institute of Electrical Engineers for examination and publication. As was expected, the paper was refused in spite of the fact (or perhaps because of the fact) that the laboratory results were conclusive. None of the present scientific institutions will publish any form of free-energy paper as that would not be good for the business of their owners.

If an inventor skips the Patent Office, avoids the scientific journals, and tries to get his invention manufactured, he needs substantial funding and that is usually blocked by the concerted efforts of the groups of companies whose businesses would be harmed by the invention becoming freely available to the public. Some times, the inventor is threatened and intimidated. I personally know several people who have had this done to them, but the most common block is financial. For example, Cal-Tech in America spent a million dollars developing, testing, proving and perfecting a carburettor which gave vastly improved mpg results and which cut pollution to near zero. They teamed up with the very large auto-parts supplier Arvin Meritor to put the carburettor into production vehicles. Then "One Equity Partners" bought out the Arvin Meritor division which did all the final work, and then they created a new company, “EMCON Technologies”, which dropped the carburettor from their product line, not because it did not work but because it did work. Oil sales were the only interest and cutting pollution was seen as irrelevant.

The Practical Situation

Some of this is quite difficult to absorb and understand, so perhaps a little extra detail may be helpful. Just to recap; there are two separate and totally different systems: the law and the legal system.

The law boils down to "don't harm anyone or his property, steal his property or swindle him". That is pretty straightforward and it is binding on everyone. You will notice that it does not say anything about keeping to a speed limit, paying taxes, getting married, serving in an army, voting in an election, or any one of thousands of other things. Those things are not required by the law. The requirements of the law are “don’t harm anyone, damage or steal his property or defraud him”, nothing else.

The legal system is an invention intended to do exactly the opposite, namely, harm you, steal your property, subject you to the will of someone else and to defraud you generally. The operating method is lies and deception and a prolonged attempt to prevent you finding out the facts. Thankfully, being subject to the legal system is optional – completely your own choice. So, by refusing to consent to being subject to it, you can shrug it off and live a life free from it.

One of the really difficult things to understand is finance. For example: Al Baker, decides to set up a finance company, lending money and charging interest on the loans. He registers “The Swindle Finance Company Limited”, which is a paper invention of the legal system and is not actually a real thing at all – just some pieces of paper and a name written into a list of paper companies.

His friend Charles Daly who lives across the street, decides to deposit £10,000 (or dollars, or Euros, or whatever the local currency is called) with Al because Al is offering 10% annual interest on all deposits as a special advertising promotion. Al puts the money in the bank account of Swindle Finance Company Limited and enters the amount as a credit in the company accounts ledger. Big smile – the business is starting to roll in.

Gary Hughes then decides that he could do with a round-the-world holiday cruise and so he asks Al for a loan of £10,000. Al is delighted and is about to lend him the £10,000 which Charles lodged when his financial director, Ed Foyle, says “hey, you can’t do that, there is a (statute) law against it - if Charles suddenly need money for something and wants to withdraw his money, you have to be able to repay him in full, so you are not allowed to lend his money to anyone else”.

Al is a bit stumped by that and asks “how can we lend money then – it seems impossible?”. It’s quite ok says Ed, we just invent the money. Here, get Gary Hughes to sign this form, but make quite sure that the form says “Mr Gary Hughes” or “MR GARY HUGHES” as that is very important. When the form is signed, we can enter it in our company accounts as a credit because his signature makes it a promissory note which has a value of £10,000 for us. Then, we start making real money by writing him a cheque instead of handing him money. He will sign that cheque in order to cash it and that is worth another £10,000 to us. This is great business as we can enter his signed cheque into our ledger as another £10,000 asset, and write the £10,000 which goes into his account as a debit. We have now got £20,000 coming in and only £10,000 going out, so we are already ahead by £10,000 and it isn’t even time for lunch on our first day. Also, if Gary pays back the loan and our 20% interest, then this transaction will have made us a net profit of £22,000. If he didn’t pay us back anything, we would still be £10,000 ahead, so let’s celebrate.

Poor Al is a bit confused, so he asks “but where does the £10,000 that we lend Patrick come from?”. Ed laughs and says, it doesn’t come from anywhere, we just write numbers into our ledger against the name of Mr Gary Hughes – it doesn’t cost us anything – do you think he would hold still long enough for us to stamp “sucker” on his forehead? After all, he is about to pay us more than twice, which means that we will make millions in profit each year. Poor Al is still confused, which is a pity, as Gary is the only person which Ed wants to keep confused about the transaction.

Ed knows all of the legal angles and when he is driving home he exceeds the speed limit. It is not dangerous in any way as there is no other traffic, and the road conditions are perfect. A police car pulls alongside him and indicates that they want him to stop, so he pulls over and stops. A police officer approaches and asks Ed if he is aware that he was driving at 40 mph in a 30 mph zone. Ed says that he was indeed aware of that.

The police officer then asks Ed for his name and address. But, Ed is aware of the fact that this is a fraudulent attempt to get him to agree to “Joinder”, that is, agreeing that he is subject to all legal statutes, giving the police officer authority over him. So, he promptly states that the law does not require him to provide any such information, he also mentions the fact that the law does not require him to drive at, or below, 30 mph in a 30 mph zone. The police officer tries this again several times, getting the same answer each time.

Being a bit stumped by this unexpected response, the police officer switches tactics and says that he may have to take Ed down to the police station for further questioning and asks if Ed understands. Being well up on legal tactics and realising that asking “do you understand” is a fraudulent attempt to establish Joinder, he calmly states that under the law, he is not required to go to a police station and he does NOT “stand under” the police officer or his statement. He also remarks that if he is taken to a police station unlawfully and against his will and without his consent, then he will take action against the police officer personally as a man and not as a police officer, for his unlawful actions. He also asks the police officer if he is aware that the Police Authority which employs him is not a government agency but is a commercial for-profit company with no powers whatsoever to uphold the law, that the police officer is only empowered to uphold the law through the oath which he personally took when he became a police**man** and it has nothing whatsoever to do with any form of authority coming from his employers. In other words, he is on his own on this one.

Ed further points out that under the law, there has to be a victim (who has been injured, has his goods damaged or stolen, or who has been defrauded) and he asks the police officer to identify the victim in this case. He also remarks that legal statutes only have the force of law for those people who consent to be bound by them, and he does NOT consent to be bound by them, and so, driving at 40 mph in a 30 mph zone where nobody was endangered and no harm or damage occurred, is not an offence for him.

I’ll leave you to work out the likely outcome of the conversation between Ed and the police officer.

Six months later, Ivan Johnson, a friend of Gary Hughes, remarks that Gary is looking worried and asks him if anything is wrong. Gary, who is self-employed, says that business has been very poor for some time and he is having financial problems. His main difficulty is this loan that he has with the Swindle Finance Company Limited. He has not been able to keep up the payments and he has just has a letter from them saying that he has to pay £2,231.47 by Friday, or they will take him to court. Fortunately, Ivan is familiar with both finance and legal matters, so he tells Gary what to do. His advice is simple, he says; for your contract with the Swindle Finance Company Limited to be valid, it has to meet these requirements:

1. Full disclosure, which didn’t happen as they did not tell you that your signature created the credit.
2. Equal Consideration, which didn’t happen as they have nothing to lose as they didn’t bring anything to the table.
3. Lawful terms and conditions
4. Signatures of the Parties, which didn’t happen as companies can’t produce a “wet ink” signature.

So, you send them a letter agreeing to pay any financial obligation which you might lawfully owe, as soon as they:
1. Provide validation of the debt, that is, the actual accounting.
2. Verification of their claim against you, that is, a sworn affidavit or a signed Invoice.
3. A copy of the Contract binding both parties.

Sign the Letter “Gary Hughes” (**not** “Mr Gary Hughes”) and write “All Rights Reserved” after your signature. Send the letter by registered delivery so that there is a third-party record of it being delivered to them.

The financial institution can’t validate the debt as they never sustained a loss. They can’t verify any claim against you as their billing is to “Mr Gary Hughes” or “MR GARY HUGHES” or “Mr G. Hughes” or “Hughes, Mr G” or some such wording, and none of those is you, since you are the man Gary Hughes. They can’t produce a copy of the contract, because one doesn’t exist – what exists is an unenforceable unilateral contract with no standing in law.

If they send you a statement of account, then tell them that a statement is not an Invoice and that you need an Invoice. If they send you a photocopy of your loan application form, then tell them that it is not a contract, being signed by only one of the parties.

If they delay and delay, then write and tell them that if they do not provide the requested documentation within fourteen days, that you will consider any debt as being fully discharged.

If they are ill-advised enough to attempt to take you to court, send a copy of your letter agreeing to pay provided they produce the evidence that there is something outstanding to pay, to the court. They may well be penalised by the court for wasting court time as courts only adjudicate between parties who disagree and there is no disagreement in your case as you have agreed to pay if the Swindle Finance Company Limited shows you that you are liable to pay them some amount of other.

Having had this explained to him, I will leave it up to you to decide if Gary felt any better about his situation.

The legal system is very large and very complex. This is quite deliberate and it is intended to make sure that no ordinary person knows all of it. Fortunately, the law is much less complicated and if you are very careful not to walk into any of the traps set for you, you can effectively ignore the legal system. If required to sign anything and you decide to do so, then Gary Hughes should sign it “By: Gary Hughes, agent” or “By: Gary Hughes, principal” as that you are not taking on any responsibilities in the strawman’s name.

John Harris of the TPUC organisation, has found a very effective technique for dealing with the attempts of the legal people to extract money from you, is to never go to court (remember that a ‘Summons’ is only an invitation and you can decline it) and returning all correspondence marking it “No Contract – Return to Sender”. This avoid you ever walking into a “Joinder” trap and becoming liable for the fraudulent claims being made against your strawman. I suggest that you research this subject further and become completely familiar with your rights under common law, and the fraudulent “Joinder” traps being set for you. What you decide to do after that, is entirely up to you.

The Situation in Australia

It appears that both the government and the legal system of Australia are null and void as the basis on which they were created no longer exists. Sir Harry Gibb has this to say about the situation:

I am a former member of the High Court and I wish to take this unusual method of informing you about a matter that is going to deeply affect us all. Unfortunately, a document such as this is too easily "lost" in the bureaucratic jungle in which we operate.

A group of Australian Citizens have taken it upon themselves to test the validity of our current political and judicial system. Like you, I have lived my entire legal career with the assumption that the basis for our legal and political system, state and federal, was written in stone. This group has undertaken to present this paper where they test the legal system.

The group is articulate, well educated and has some of our best legal minds amongst its members. One of Australia's best known barristers is one of the group's leading lights. It is far better informed with regard to international law than most members of the judiciary or for that matter, the legal academe. It has better international contacts than I would have thought possible.

After spending some time with the group leader, I was able to elicit it's primary intentions. It is the introduction of a totally democratic system of government devoid of party politics operated by the will of the people incorporating a system of debit taxation which should go a long way to eliminating the current unemployment problem and addressing other pressing social issues. An A.B.S. financial model supports the proposal.

The group has so far concentrated on matters relating to taxation, state and federal, minor industrial and motor traffic while undertaking not to present a criminal defence using their current presentation. I challenged the leader of this group to present any evidence which he had with regard to the above defence so that I could use my legal expertise to play the part of devil's advocate. It should be brought to your attention that the group has access to documentation of which we members of the judiciary have little knowledge. I refer to the British Parliamentary Papers for the Colony of Australia for the years 1860 through to 1922.

These are photocopies of all documents correspondence etc., between the states and later the Commonwealth of Australia, the British Crown and the British Government. They are very revealing documents and indicate the degree of chicanery in which the politicians of all shades were involved and as I can now see, at the expense of the legal academe and the judiciary. I present for your perusal the details of the group's presentation along with my comment on each major item. The group relies solely upon historical fact and rejects political rhetoric and legal opinion unless based upon historical fact.

1. "The Commonwealth of Australia Constitution Act 1900 (UK) is an act of the parliament of the United Kingdom. It did not contain any substance of sovereignty and was a colonial act centralising self-government of the six Australian Colonies. Australia remained a colony of the United Kingdom."

1a. Although the late Lionel Murphy attempted to show that there was an element of sovereignty in this act, he failed to do so. The international definition of sovereignty has been espoused at length and the above act although important in the development of Australia, did not have the authority of sovereignty. The historical evidence that Australia remained a British Colony post 1901 is overwhelming.

2. "Australia made an international declaration of its intention to become a sovereign nation when Prime Minister Hughes and his deputy; Sir Joseph Cook signed the Treaty of Versailles on June 28, 1919. On its cognisance of signing this treaty, Australia was granted a "C" class League of Nations mandate over former German territories in the Pacific. In effect, Papua New Guinea became a colony of Australia achieving its own independence on 16 September 1975. The League of Nations became part of International Law on 10 January 1920 with Article X of the Covenant of League of Nations guaranteeing the sovereignty of each member."

2A. The Significance of Australia joining the League of Nations as a foundation member has never been addressed in Australia before. Strangely, only one book has ever examined the question of Australian independence. Written by W. J. Hudson and M. P. Sharp in 1988 "Australian Independence" printed by Melbourne University Press. As both were members of the Department of Foreign Affairs and Trade at the time of authorship and had access to the, British Parliamentary Papers, I find it most interesting they have avoided any mention of these papers in their book. Their conclusion that Australia became an independent nation via. the Statute of Westminster in 1931 flies in the face of contradictory evidence within the above mentioned papers and readily available historical fact.

Prime Minister Hughes address to the Commonwealth Parliament on 10 September 1919, “Australia has now entered into a family of nations on a footing of equality. Australia has been born in a blood sacrifice" demonstrates that the politicians of the day were only too well aware of the change of status from a colony to that of a sovereign nation, while attempting to remain within the Empire.

Prime Minister Bruce made this reply to the British Government in 1922 after a request for troops against Kernel Ataturk in the Chanak crisis. Bruce’s reply is contained in the British Parliamentary Papers: “We have to try to ensure there shall be an Empire foreign policy which if we are to be in anyway responsible for it, must be one to which we agree and to which we have assented. If we are to take any responsibility for the Empire's foreign policy, then there must be a better system, so that we may be consulted and have a better opportunity to express the views of the people of this country. We cannot blindly submit to any policy which may involve us in war." This is a far cry from the declaration of war against Germany made on behalf of the British Colony of Australia by George V of the United Kingdom in 1914.

I have reproduced Bruce's reply in full as I believe this reply contains clear historical evidence of a Prime Minister who was well aware of the change of status from a. colony to a sovereign nation. The later Statute of Westminster 1931 was an acknowledgment of that status.

3. "Paragraph 4 of the Statue of Westminster Act 1931 contravenes Article X of the Covenant of the League of Nations. Paragraph 1 of the Australia Act 1986 contravenes Article 2 paragraphs 1 and 4 of the Charter of the United Nations."

3A Paragraph 4 of the Statute of Westminster reads "No Act of Parliament of the United Kingdom, passed after the commencement of this Act, shall extend, or be deemed to extend, to a Dominion as part of the law of that Dominion, unless it is expressly declared in that Act, that the Dominion, has requested, and consented to the enactment thereof." Paragraph 1 of the Australia Act is very similar: “No Act of the Parliament of the United Kingdom passed after the commencement of this Act shall extend, or be deemed to extend, to the Commonwealth, to a State or Territory as part of the law of the Commonwealth, of the State or of the Territory."

I passed this one to the Federal Attorney General and asked him what was the source of this quite incredible authority that sought to overturn the authority legislated within the Covenant of the League of Nations in Article X and the Charter of the United Nations in Article 2 paragraphs 1 and 4. He is unable to provide any documentation to support these clauses, Article X of the Covenant of the League of Nations states: “The members of the League undertake to respect and preserve against external aggression the territorial integrity and existing political independence of all Members of the League. In case of any such aggression or in case of any threat or danger of such aggression, the Council shall advise upon the means by which this obligation shall be fulfilled."

It is appropriate that I now introduce a statement by Sir Geoffrey Butler KBE, MA and Fellow, Librarian and Lecturer in International Law and Diplomacy of Corpus Christi College, Cambridge author of “A Handbook to-the League of Nations" used as a reference to the League by virtually all nations at that time. He refers to Article 1 of the Covenant of the League of Nations:

"It is arguable that this article is the Covenant's most significant single measure. By it the British Dominions, namely New Zealand, Australia, South Africa, and Canada, have their independent nationhood established for the first time. There may be friction over small matters in giving effect to this internationally acknowledged fact but the Dominions will always look to the League of Nations Covenant as their Declaration of Independence.

Article 2 paragraph 1 of the United Nation’s Charter states "The Organisation is based on the principle of the sovereign equality of all of its Members."

Article 2 paragraph 4 of the Charter states ‘All members shall refrain in their international relations, from the threat or use of force against the territorial integrity or political independence of any state, or in any other manner inconsistent with the Purposes of the United Nations."

In view of the above, the historical evidence for Australian Independence by 10 January 1920 when the League of Nations became part of International Law is overwhelming. When this evidence is reinforced with the contents of the Charter of the United Nations, the continued usage of any legislation that owes its very legitimacy to the parliament of an acknowledged foreign power cannot be supported by either legal opinion or indeed historical evidence.

I therefore have come to the conclusion that the current legal and political system in use in Australia and its States and Territories has no basis in law.

Following discussions with members of the British Government relating to the Letters Patent for the Governor General and State Governors I find that these documents no longer have any authority. Indeed, the Queen of the United Kingdom is excluded from any position of power in Australia by the United Nations Charter and is excluded under UK law from the issue of a Letters Patent to other than a British Subject. A Letters Patent must refer to an action to be taken with regard to British Citizens. In the Immigration Act 1972, the UK defines Australian Citizens as “aliens”.

The Governor General’s Letters Patent is a comedy of errors. We are greeted in the name of the Queen of Australia who suddenly becomes the Queen of the United Kingdom in the next paragraph of the Letters Patent. This Queen then gives instructions to the Governor General with reference to the Commonwealth of Australia Constitution Act 1900 UK. Here we have a clear breach of Article 2 paragraph 1 of the United Nation Charter. Under both UK and international law, the-Queen is a British Citizen.

State Governors are in a worse position since their authority comes from the late Queen Victoria of the United Kingdom. Regardless of the validity of the Commonwealth of Australia Constitution Act 1900 UK, if the authority of Governor General and the State Governors is invalid then so is the entire political and legal system of government.

When advised that the War Crimes Commission was taking an interest, I called them in Geneva. Under the 1947 Geneva Convention, they are empowered to look into cases here in Australia where it is alleged that the law of a foreign country was enforced against a citizen of a member state of the United Nations. As they perceive that only the judiciary can actually enforce the law, the judiciary becomes their target. The group has already placed cases before them which they are currently investigating. If found guilty, the penalties are horrific and include the death penalty!

I could go on with more relevant information however I think now is the time for a summary. The group leader, a QC, states the obvious when he asked me how could a colony now acknowledged by all world nations to be a sovereign Nation, retain exactly the same legal and political system which it enjoyed as a colony, without any change whatsoever to the basis for law. This point alone requires an answer.

The High Court has already answered with regard to the position held by treaties signed by the Commonwealth Government in the Teoh case of 1994. "Ordinary people have the right to expect government officials to consider Australia's international obligations even if those obligations are not reflected in specific Acts of Parliament: the rights recognised in international treaties are an implied limit on executive processes."

My advice is to adjourn any case "sine die" that challenges the authority of the Letters

Patent. Under no circumstances hear a case that challenges the validity of a State or the Federal Constitution. It is the politicians who are using us as pawns without them having to face the music. If these matters are of concern to politicians, then let them sort out these problems and accept any inherent risks themselves! Article 36 of the Statute of the International Court of Justice is the correct reference for you to refuse to hear a matter when an international treaty is cited as a defence.

The Comments of Brian Collins

The following is some of what the very knowledgeable Brian Collins has to say on his web site. I merely quote what he says here and I have not verified any of this material, and so I recommend that you check out these things for yourself.

The Greatest Lie Ever Told

The government and legal system of the United States, Canada, Australia, New Zealand and of course, Britain, is totally controlled by the Crown. The Crown is **not** the British Monarch. The Crown is the Inner City of London, which is an independent State in London belonging to the Vatican system. It is a banking cartel which has a massive system around and beneath it, which hides its true power. The City is in fact, the Knights Templar Church, also known as the 'Crown Temple' or 'Crown Templar', and is located between Fleet Street and Victoria Embankment. The Temple grounds are also home to the Crown Offices at Crown Office Row.

The Crown Temple controls the Global 'Legal' system, including those in the United States, Canada, Australia, and much more; this is because all Bar Associations are franchises of the International Bar Association at the Inns of Court at Crown Temple based at Chancery Lane in London. All Bar Associations are franchises of the Crown and all Bar Attorneys/ Barristers throughout the world pledge a solemn oath to the Temple, even though many may not be aware that this is what they are doing. Bar Association 'licensed' Solicitors / Barristers must keep to their Oath, Pledge and terms of allegiance to the Crown Temple if they are to be "called to the Bar" and work in the legal profession. The ruling Monarch is also subordinate to the Crown Temple, this as been so since the reign of King John in the 13th century when Royal Sovereignty was transferred to the Crown Temple and, through this, to the Roman Church. King John 1167-1216 is the key to this deception.

It was at the Chancel, or Chancery, of the Crown Inner Temple Court in January 1215 that King John was faced with the demands of the French/English Barons in England (mainly French), to confirm the rights enshrined in the Magna Carta. When he signed the Magna Carta in 1215 history records this as an event that extended human freedom, but the real affect was very different as we shall see. The governments of the USA, Canada, Australia and more, are subsidiaries of the Crown Temple and so is the US Central Bank the Federal Reserve, as are all Central Banks on the planet, including the IMF World Bank.

Bar Associations are awarded their franchises by the Four Inns of Court at Temple Bar. These are the Inner Temple, Middle Temple, Lincolns Inn and Greys Inn and they are nothing less than elite secret societies without charters or statutes. They are the law unto themselves. The Inner Temple controls the legal system franchise for Canada and Britain while the Middle Temple does the same for the United States. Queen Elizabeth II is a member of both Temples. At least five signatories to the American Declaration of Independence were Temple Bar Attorneys who had pledged allegiance to the Crown! Another Middle Temple operative during the formation of the USA was Alexander Hamilton who structured the American Banking system to fulfil the Crown

Temples agenda for total control of the United States. So in truth, a State wherever it is on this planet, is a legal entity of the Temple Crown, or a Crown Colony. A man named Michael Edwards wrote:

"Americans were fooled into believing that the legal Crown Colonies comprising New England, were independent nation states, but they never were, nor are they today. They were, and still are, Colonies of the Crown Temple, through letters patent and charters, who have no legal authority to be independent from the rule and order of the Crown Temple. A legal state is a Crown Temple Colony".

"Neither the American people nor the monarch of Britain own America. The Crown Temple owns America through the deception of those who have sworn their allegiance by oath to the Middle Temple Bar. The Crown Bankers and their Middle Templar Attorneys rule America through unlawful contracts, unlawful Taxes, and contract documents of false equity through debt deceit, all strictly enforced by their completely unlawful, but 'legal', orders, rules and codes of the Crown Temple Courts, or the so called, 'Judiciary', in America. This is because the Crown Temple holds the land titles and estate deeds to all of North America".

Seven Middle Inn Templars who had pledged an oath of allegiance to the Crown Temple (including Alexander Hamilton) were among the members of the Constitutional Convention who signed the completed 'American Constitution'. How symbolic it is that copies of the American Constitution and the Declaration of Independence hang on the wall of the Middle Temple in London. It's not that surprising when you consider that this Temple controlled both sides in these shenanigans.

So while the Middle Bar Templars were orchestrating the illusion of freedom from the perceived rule by King George III, the King too, was a sworn member of the same Temple. Michael Edwards continues:

"1776 is the year that will truly live in infamy for all Americans. It is the year that the Crown Colonies became legal Crown States. The Declaration of Independence was a legal, not lawful, document. It was signed on both sides by representatives of the Crown Temple. Legally, it announced the status quo of the Crown Colonies to that of the new legal name called 'States' as directly possessed estates of the Crown.

"The American people were hoodwinked into thinking that they were declaring lawful independence from the Crown. The proof that the colonies are still a Crown possession is the use of the word 'State' to signify a 'legal estate of possession'. Had this been a document “of and by the people”, then both the Declaration of Independence and the US Constitution would have been written using the word 'States'. By the use of 'State', the significance of government of estate possessions was legally established. All of the North American States are Crown Templar possessions through their legal document, signed by their representation of both parties to the contract, known as the Constitution of the United States of America.

Who controls the Crown? On 15th May 1213, King John, being a puppet of the Knights Templar, effectively signed away the Kingdom of England and Ireland to Pope Innocent III and the Roman Church, witnessed by the Crown Templars. As King John said at the time: "I myself bearing witness in the house of the Knights Templars".

The King John Charter said:

" We wish it to be known to all of you, through this our charter, furnished with our seal… not induced by force or compelled by fear, but of our own good and spontaneous will and by common counsel of our Barons, do offer and freely concede to God and his Holy Apostles Peter and Paul and to our mother the holy Roman Church, and to our lord Pope Innocent and to his Catholic successors, the whole kingdom of England and the whole kingdom of Ireland, with all their rights and appurtenances… we perform and swear fealty for them to him are aforesaid lord pope Innocent, and his Catholic successors and the Roman Church… binding our successors and our heirs by our wife forever, in a similar manner to perform fealty and show homage to him who shall be chief pontiff at the time, and to the Roman church without demur. As a sign… we will and establish perpetual obligation and concession… from the proper and especial revenues of our aforesaid kingdoms… the Roman church shall receive yearly a thousand marks sterling… saving to us and to our heirs our rights, liberties and regalia; all of which things, as they have been described above, we wish to have perpetually valid and firm; and we bind ourselves and our successors not to act counter to them. And if we or any of our successors shall presume to attempt this, whoever he be, unless being duly warned he come to his kingdom, and his senses, he shall lose his right to the kingdom, and this charter of our obligation and concession shall always remain firm."

Now it gets interesting. Historical accounts concentrate on the fact that this charter obliged the Crown to pay money to the Roman Church, but it also states that if the terms of the charter are broken, the 'right to the kingdom' shall be lost. When King John signed the Magna Carter on 15th June 1215, he broke the terms of the charter with the Pope and therefore lost the right to his Kingdom. Pope Innocent III then declared the Magna Carter to be null and void. From that time, the 'Crown' passed from the Monarch to the Knights Templar who to this day, govern Britain on behalf of the Roman Illuminati Church.

The St Clair's now Sinclair are the initial directors of this link of Templar and Rome in the British Isles as they took hold in Scotland at the time of the 1066 Norsemen-Norman invasion. This means that ultimately, through the Crown Temple, the Roman system also owns the United States, Canada and all countries and Bar associations controlled both overtly and covertly by the Crown. This is why the Peace Treaty between the American Colonies and the British Crown in 1783, stated:

"It having pleased the Divine Providence to dispose the hearts of the most serene and most potent Prince George the third, by the grace of God, King of Great Britain, France and Ireland, defender of the faith, Duke of Brunswick and Luneburg, arch treasurer and prince elector of the Holy Roman Empire etc… and of the United States of America…"

And ironically, a Roman Catholic is barred from being the British Monarch while all along the Monarch and the Kingdom have been owned by the system that is Rome.

The Queen is the Grand Patroness of Freemasonry. She is served by the 390 members of the Privy Council which connects with it’s equivalent in all other Commonwealth Countries. The Privy Council is 'LEGALLY' above Parliament because of its prerogative powers. It’s members, are appointed for life and they include Prince Philip, Prince Charles, the Archbishop of Canterbury, the Prime Minister and many others. They hold nine official meetings each year and the government (Crown) minister's stand to attention while the Queen is told of the government measures they are asking the Queen to approve, which are nothing other than what the Crown dictates via the elected leader and via the Whips of whichever political party has power... After taking their bow to the Queen and shaking her hand they are sworn to conduct their business in the utmost secrecy.

Another network of this structure is the CROWN AGENTS. Formed in 1833 as 'Crown Agents for the Colonies', to run the day to day administration of the empire and to serve as private bankers to government officials, colonial authorities, and heads of state. It is also an older version of Brown & Root supplying a vast range of goods throughout the empire. Goods that included arms, drugs, viruses, especially to Africa to create the genocidal wars we are now witnessing and have witnessed in the past. The ‘Crown Agents’ is the network which links the Crown Temple to the organised crime operations throughout the empire, the Golden Dawn being one of the most powerful occult operations to be used in Britain amongst the crime syndicates to ensure that the right crime waves are in full swing when required.

We can see this in the current agenda for guns. The Golden Dawn also operates within legal organisations, but is the interconnecting network across all secret societies and religion. Remember that the Crown Agents work directly for the Monarch who works for the Knights Templar Church, which operates for the Vatican, and to add insult to injury, the entire debt of the Crown Agents is guaranteed by the British Government, and that means you!

In the 1970's it was bailed out by the Bank of England costing hundreds of millions of pounds. For many years the Crown Agents managed the personal wealth of the Sultan of Brunei who just happens to be a great friend of the Queen, and who has funded many of Prince Philips', Prince Charles', and George Bush senior's private projects. The Sultan is also the financier of both the British and the American unofficial intelligence operations as he has backed many of Mohammed Al Fayed's operations, in fact the Sultan could be said to be Mohammed Al Fayed!

After the murder of Princess Diana, the role of Al Fayed was for him to hijack the conspiracy and thus lead investigators down the Al Fayed rap of misinformation as was done with Nick Brown over the top-up fees debate, and is currently being played by David Davis. Fortunately no one needed to go to him for information because we all in our hearts already know that she was murdered.

In 1996 the 'Crown Agents' operation was privatised and given the name 'Crown Agents for Overseas Government and Administration Ltd'. Of course, privatisation is nothing but transfer of Power from Crown Temple through Government agency to Crown Temple via direct ownership: they own everything in this nation!

Just to give an idea of What the Crown Agencies controls, here are a few little companies which it controls. It acts as a holding company for:

Barclays bank
Standard and Chartered bank
Unilever
Tate and Lyle
Securicor
British Telecom
The Prince of Wales Business Leaders Forum, and
Aga Khan Foundation

I think you get the picture; it's big to say the least.

It manages the customs services of Mozambique, and through a company called Europe SA, it is in charge of all of the economic construction procurement for Bosnia. It is also in a joint venture with the Monaco-based company ES-KO, to provide all the food for United Nations peace keeping forces in Angola and Bosnia. So, the more war the more profit for the Crown Agents, and if it were to fail financially, then the British Taxpayer will have to foot the bill !!!!

The queen of England owns the 40,000 acre Duchy of Lancaster, and the 44,000 acre Duchy of Cornwall which gives Charles his income. In truth, it is the Crown that owns these assets, which are assigned to the ruling monarch, so long as they do as they are told. The Crown, it transpires, owns land in the UK to the tune of 40 million acres. The Queen owns over 300 residences around the country, and invests heavily in corporations like Rio Tinto Zinc, Royal Dutch Shell, ICI, and General Electric. This is no surprise as these companies are 100% Illuminati operations.

Rio Tinto is the largest mining company in the world and was established in 1873 by Hugh Matheson of the Global drug running operation Jardine Matheson. Rio Tinto was in at the start of the North Sea Oil, along with Texaco. They used the refineries of BP in which the Queen also has massive investments, so now you know where all the revenues from the North Sea oil reserves went - to the Crown Temple. This shows insider dealing on an individual basis enabling the Queen to make massive profits.

Another blatant conflict of interest to have been identified, was Rio Tinto's involvement in a cartel formed in 1971 to fix the price of uranium. A Federal grand jury and the 1976 US Senate Foreign Relations Committee, chaired by Frank Church, exposed the sting. It also included a company called Mary Kathleen Uranium of Australia. This company had been secretly encouraging the Aborigines to occupy uranium-rich lands in Australia to take these lands out of production in order to raise the price of uranium on the world market. The manipulated shortage of uranium had a serious effect on the American Westinghouse company who sought to take legal action against Rio Tinto for price rigging.

This strategy has been used in the USA against the Native Americans and throughout Africa. An American court ordered that Rio Tinto officials answer questions, but this was quashed by the British Law Lords. The Australian government passed legislation to the same effect. This was after the Australian Prime Minister, Gough Whitlam, had been dismissed from office by the Queen’s Governor General of Australia, Sir John Kerr. Whitlam was pursuing a policy of buying out the mining and raw material cartels, like Rio Tinto and Anglo American, to stop them raping Australia's resource base, while giving nothing in return.

The Queen having enormous investments in both companies, removed Whitlam by using some of her wide range of prerogative powers, which by the way, she has in all commonwealth countries including Britain, which she can instigate when the Crown deem necessary, but of course in the minds of the masses the Queen has no powers today! Well I suppose she doesn't in that she is a puppet of the Crown Temple and ultimately, of the Roman system. Sir John Kerr, a former high level operative of British Intelligence, was made a member of the Privy Council and the Royal Victorian Order for his loyal and most profitable service to the Queen’s portfolio.

He was later murdered however, when the truth about the removal of Gough Whitlam was in danger of coming out - how they look after their own! He was obviously outer circle, and a good man and would have exposed the lies of the inner circle. The Crown Cartels continue through a House of Windsor extremely secretive society called the Club of the Isles. It was named after King Edward VII, Queen Victoria's son.

The title is held today by Prince Charles. King Edward VII was heavily involved with the Black Nobility barons of ‘the square mile of London’ Financial District and helped them to engineer the Crimean War, the Russia - Japan War, the preparations for the First World War, and the Opium Wars against China. Through the central organisation of the Club of the Isles comes the fantastic web of interlocking directorships which holds apparently 'independent' companies in a network of common control and common agenda. Part of that web includes:

The Bank of England
Anglo American Corporation of South Africa
Rio Tinto
Minorco Minerals and Resources Corp
De Beers Consolidated Mines
De Beers Centenary AG
N.M Rothschild’s Bank
Barclays Bank
Lloyds Bank
Lloyds Insurance Market
HSBC Bank
National Westminster Bank
Barings Bank
Schroders bank
Standard Chartered Bank

Hambros Bank
S.G Warburg
Toronto Dominion Bank
Johnson Matthey
Kleinwort Benson Group
Lazard Brothers
Lonrho
J.P Morgan and CO
Morgan Grenfell Group
British Petroleum
Shell and Royal Dutch Petroleum
Cadbury - Schweppes
Bat Industries
Assicurazioni Generali SpA (VeniceItaly)
Courtaulds
General Electric
Cazeenove and Co
Grand Metropolitan
Hanson PLC
HSBS (Hong Kong and Shanghai Bank)
Imperial and Chemical Industries (ICI)
Inchscape PLC
Inco Ltd.
ING Group
Jardine Matheson
Peninsular and Oriental Steam Navigation & Co (P & O ferries)
Pilkington Glass
Reuters Holdings
Glaxo Wellcome
Smithkline Beecham
Unilever and UnileverNV
Vickers PLC.

This is just a few of them. In 1999, Lonrho had 640 subsidiary companies itself; today, it has many more, and all of these companies have themselves, staggering numbers of subsidiaries. In studying the subsidiaries of the multi-nationals, you arrive at the fact that everything is controlled by the Crown, and that all of them lead back to operatives of the Roman Illuminati Church via the Knights Templar Church.

A fact worth noting is that just because a company like Pilkington Glass is now perceived to be owned by a non- British company, it has only moved from the British economy, not from the control or economy of the Illuminati who own everything, this type of movement is only a movement within the global conglomerate that is the New World Order and still earning for, and controlled by, the bloodline elite, albeit via a different branch of the elite tree.

Just look at some of the TV companies owned and thus controlled by General Electric:

NBC network
CNBC
MSNBC
Bravo
MUN2 TV
Sci-Fi channel
Trio
WNBC - New York
KNBC - Los Angeles

WMAQ - Chicago
WCAU - Philadelphia
KNTV - San Jose - San Francisco
KXAS - Dallas - Fort Worth
WRAC Washington
WTVJ - Miami
KNSDF - San Diego
WVIT - Hartford
WNCN - Raleigh
WCMH - Columbus
WVTM - Birmingham (USA)
WJAR - Providence
KVEA / KWHY - Los Angeles
WNJU - New York
WSCV - Miami
KTMD - Houston
WSNS - Chicago
KXTX - Dallas
KVDA - San Antonio
KSTS - San Francisco
KDRX - Phoenix
KNSO - Fresno
KMAS - Denver
WNEU - Boston / Merrimack
KHRR - Tucson
WKAQ - Puerto Rico
Universal Studios
NBC Universal Television Studio
NBC Universal Television Distribution.

This is one company controlling a major chunk of the TV dream state given out to the whole of America. Is it any wonder that Americans are completely under the control of the American elite?

Another important part of the Windsor network which is part of the Crown Temple, are the City Livery Companies. These purport to represent the various groups of merchants like the gun makers, stationers, newspaper makers, goldsmiths and the like. They are in fact, very secret societies, fundamental to the control of the City institutions and much further afield. In the 1350's, in the wake of the plague known to history as the Black Death, the government of the City passed from the ward councils to the City Livery Companies. In 1979, the year when Margaret Thatcher took power, the Honourable Company of Freemen of the City of London and of North America, began to hold meetings in New York and Toronto, and on 21st October 1991, the Association of Liverymen of the City of London in Hong Kong was founded and all their members were Architects (Freemasons). The late author Peter Jones, researched some of the Livery Companies in the 1990's for his book,' The Obedience of Australia', which exposed the manipulation which led to the removal by the Queen, of Australian Prime Minister, Gough Whitlam. These are some of the names which he found within these companies:

Engineers: The Duke of Edinburgh.

Airline Pilots and Navigators: The Duke of Edinburgh Prince Andrew

Butchers: Queen Mother, Lord Vesty (of the meat family and Lord Prior of the Order of St John of Jerusalem)

Merchant Tailors: Queen Mother, Lord Whitelaw

Glovers: Margaret Thatcher, Sir John Fieldhouse (Admiral of the Fleet during the Falklands conflict)

Poulterers: Margaret Thatcher, Duchess of Devonshire.

Fishmongers: Duke and Duchess of Devonshire, C.E.A

Hambro (Hambros Bank, Taylor Woodrow, and P&O), Lord Inchcape (Her Majesty's Lieutenant of London)

Goldsmiths: J.H Hambro.

Grocers: Edward Heath.

Salter's: Duke of Kent (Grand Master of English Freemasonry) Lord Armstrong.

Cloth workers: Sir Peter Gadson (a Grand Master of the United Grand Lodge), Lord Carrington (Thatcher's handler).

Another name prominent within these companies is McAlpine of the construction family.

You will of course have noted that Prince Philip heads the Pilots and Navigators, which gives indication as to whom is in control of the current attack on our right to travel by plane and the whole swath of legislation about to come out relative to air traffic, using the environment scam to force it through. Just as a matter of interest, the cheap-flight operator ‘Easy Jet’ is financed by the Warburg Bank which is part of the Rothschild empire which has been proved beyond doubt, to have funded the rise of Hitler's war machine on behalf of the Rothschilds.

The fact that they are now blaming these cheap flight operators for the rise in carbon emissions shows you why the Warburg bank has funded this airline, it is the catalyst for the introduction of the carbon emissions scam. Basically they will determine how much you, as a household, can travel. You have to look at this whole carbon emissions agenda as an attempt to instil a massive suppressing layer of control upon families and business via the introduction of quotas per household.

This will stifle people’s movements to unimaginable levels. Don't forget that the House of Rothschild operates directly under the current British chief, Prince Philip. Prince Philip's whole family were supporters of the Nazi's as was he himself. In 1935, Prince Christoph, the husband of Philip's sister Sophie, was a colonel in the SS of Himmler's personal staff and head of the Forschungsamt, an elite intelligence operation controlled by Hermann Goering.

It was they who carried out the famous ‘Night of the Long Knives’ when Hitler removed his key opponents. Christoph and Sophie named their eldest child, Karl Adolf, after Hitler and Prince Philip was involved in his education. Christoph's brother, Philip of Hess, was related to the King of Italy and was the official liaison between the fascists of Italy and Germany. Also at the same time the British King Edward VIII, who was forced to abdicate in order the Queen Mother could be placed in the position of Chief Toad which meant she had to marry the lesser of the brothers, Bertie, the one she could obviously control.

King Edward VIII was well known to be a Nazi supporter. Prince Philip kept up very serious connections with Edward even after his abdication in 1936. Another of Edward's supporters, and mentor to Prince Philip, was the known paedophile and Satanist Lord Louis Mountbatten (Battenberg). Mountbatten was Philip’s route into the House of Windsor. Mountbatten was the grandson of Queen Victoria and Prince Albert and was born at Windsor Castle in 1900. While Mountbatten was supposedly fighting on the British side during the war, he maintained serious communications with the Windsor's German Clan via his sister Louise, the Crown Princess of

Sweden and wife of King Gustav. Louise was Prince Philip's aunt.

At the end of the war, in June 1945, the British King, George VI, the father of Queen Elizabeth and puppet of the Queen Mother, sent the former MI5 officer, Anthony Blunt, to the Kronberg Castle of Prince Philip's sister Sophie, and her Nazi husband Prince Christoph of Hess, to recover correspondence between the British Royal Family and their Nazi relatives, for propaganda aimed at convincing the aristocrats of Britain they had not been in contact all along. Blunt was the 'surveyor of the Queens Pictures' and a world expert in the paintings of Poussin, the initiate who painted pictures called 'The Shepherds of Arcadia' which related to the Rennes-le-Chateau mysteries. Blunt was named as a member of a KGB unit inside British Intelligence along with Burgess, MacLean, and Philby, the fifth man was never named, but was in fact, Lord Victor Rothschild.

If you have seen the latest Bond movies, you hear the Character 'M' played by Dame Judy Dench state, ' in the cold war days intelligence operatives that made a big mistake had the common decency to defect', of course they would the intelligence services of the world are one and the same. When Blunt was finally caught in the 1980's, Queen Elizabeth II demanded he was not questioned on his clandestine mission to Kronberg Castle… So who controls the law?

Another important secret society within the Crown Temple is the Knights Grand Cross of the Order of the Bath, sounds pretty strange until you understand its symbolism. Both George Bush snr. and Ronald Reagan were given this title. The resurrection bath of alchemy, symbolises rebirth and purification or absolution. Baths are given to Masonic Knights of the Bath before they perform horrendous deeds, hence the term 'Blood Baths'.

The information in the last few paragraphs only hints at the true power of the Crown Temple. One has also to include all that the Vatican openly controls, to see the true extent of the power of the Roman Illuminati Church to which the Knights Templar Church is subordinate. Through all these networks and more, thirteen Royal Nefilim families control the world, and it is they who are carrying out all of the atrocities in the world at this present time, to carry out the agenda of the Elohim.

The Crown also owns massive parts of our coastline around this nation and 12 miles out to sea, in total about half of the coastline. Some of this is under the control of the Ministry of Defence which is itself controlled by the Crown. The current legislation, under which the National Trust will purchase some of this land from the MOD and coast not belonging to the MOD, changes nothing. The National Trust is 100% controlled by the Crown. We have the British Waterways agency, and the railways again controlling massive amounts of land, and we are effectively almost back to the middle ages now.

One of the greatest means to the Windsor land-grab is the:

CLUB OF THE ISLES

Controlling the World Wildlife Fund, WWF, this is one hell of a heinous operation and given the fact that Prince Philip inherited the position as the Queen's husband, becoming Commander of the Club of the Isles...then he is at the helm of genocide the likes of which the Holocaust could never imagine.

I see that the Royals are playing the good guys relative to the Sunni Muslims with the release of the Manchester man after 18 years in prison in Pakistan, this in itself shows you who operates President Musharaff of Pakistan, via such orders as the Order of the Mystic Shrine. This is important, given that Pakistan is now under attack from NATO forces, again controlled by the Inner City banking cartel which includes the Dutch and the Swiss.

So how does the Crown control all the MPs? Answer; via the whip system. All of the MPs which you vote in to represent you, are told how to vote each day by each party's leadership via the whips. So when any politician that has ever been and will be while this system exists, tells lies to the whole population the minute he or she opens his mouth and speaks. No matter what he speaks about, it is saying what he has been told to say, how to speak and when to speak. If it does not obey the whips, then his career is over. Thus the Crown need only control the people at leadership level or the cabinet of each political party and the Whips office, then through that clique of puppets, they demand obedience from all MPs down to the MPs sitting in each constituency, claiming to be acting on behalf of their constituents. The majority of MPs don't even get to see each bill before it goes to the vote, and indeed they don't need to as they are told how to vote on every Bill.

On Sunday 11th February 2007 on the political show 'Sunday AM', Giles Brandreth, a Conservative Party whip stated:

"As a whip, we understand each MP's marital problems, their drinking problems their financial problems, we know a lot about them. We then advise and guide them to making the right decisions".

Do you still feel that MPs act according to their own understanding and emotions? Of course they do not. This is the best I have witnessed from a politician handing you on a plate how the game of politics actually operates. They are all, through fear of their personal information being leaked; totally afraid of the whips, and so do the whips' bidding, which, of course, is the Crown's bidding. All MPs who speak at the box in the Commons do so under oath to the Bible positioned under the box. What does that tell you about those who operate as very religious people (Blair) when they spew the bullshit? Blair is a high member of the Illuminati and that is why he can lie with ease as he speaks to the House and the people.

The Economic Techniques

The following is an excerpt from a document, dated May 1979, and which appears to be a statement of the methods and techniques used in the economic warfare which is being waged against all ordinary people at this time. Let me emphasise that these are not my words but that I am quoting the contents of an old and unverified document of unknown origin. Anonymous documents are a standard method of spreading disinformation, however, the statements quoted below are included because they have every appearance of being a factual New World Order strategy already being implemented.

Top Secret

Silent Weapons for Quiet Wars, An introductory programming manual, Operations Research Technical Manual TM-SW7905.1 This publication marks the 25th anniversary of the Third World War, called the "Quiet War", being conducted using subjective biological warfare, fought with "silent weapons." May 1979

Security

It is patently impossible to discuss social engineering or the automation of a society, i.e., the engineering of social automation systems (silent weapons) on a national or worldwide scale without implying extensive objectives of social control and destruction of human life, i.e., slavery and genocide. Whenever any person or group of persons in a position of great power and without full knowledge and consent of the public, uses such knowledge and methodologies for economic conquest - it must be understood that a state of domestic warfare exists between that person, or group of persons, and the public. The solution of today's problems requires an approach which is ruthlessly candid, with no agonizing over religious, moral or cultural values.

Historical Introduction

Silent weapon technology has evolved from Operations Research ("OR"), a strategic and tactical methodology developed under the Military Management in England during the Second World War. The original purpose of Operations Research was to study the strategic and tactical problems of air and land defence with the objective of effective use of limited military resources against foreign enemies (i.e., logistics). It was soon recognised by those in positions of power that the same methods might be useful for totally controlling a society, but better tools were needed.

Social engineering (the analysis and automation of a society) requires the correlation of great amounts of constantly changing economic information (data), so a high-speed computerised data-processing system was necessary which could predict when society would arrive at the point of capitulation. Mechanical computers were too slow, but the electronic computer fills the bill. The next breakthrough was the development of the simplex method of linear programming in 1947 by the mathematician George B. Dantzig. Then in 1948, the transistor, promised great expansion of the computer field by reducing space and power requirements.

With these three inventions, those in positions of power strongly suspected that it was possible for them to control the whole world. Immediately, the Rockefeller Foundation got in on the ground floor by making a four-year grant to Harvard College, funding the Harvard Economic Research Project for the study of the structure of the American Economy. One year later, in 1949, The United States Air Force joined in. In 1952 the grant period terminated, and a high-level meeting of the Elite was held to determine the next phase of social Operations Research. The Harvard project had been very fruitful, as is borne out by the publication of some of its results in 1953 suggesting the feasibility of economic (social) engineering. (Studies in the Structure of the American Economy - copyright 1953 by Wassily Leontief, International Science Press Inc., White Plains, New York).

Engineered during the last half of the 1940's, by 1954 the new Quiet-War machine was ready. With the creation of the maser in 1954, the promise of unlocking unlimited sources of fusion atomic energy from the heavy hydrogen in sea water and the consequent availability of unlimited social power was a possibility only decades away. The combination was irresistible. The Quiet War was quietly declared by the International Elite at a meeting held in 1954. Although the silent weapons system was nearly exposed 13 years later, the evolution of the new weapon-system has never suffered any major setbacks. This year of 1979 marks the 25th anniversary of the beginning of the Quiet War. Already this domestic war has had many victories on many fronts throughout the world.

Political Introduction

In 1954 it was well recognised by those in positions of authority, that it would be only a few decades, before the general public would be able to grasp and upset the cradle of power, for the elements of the new silent-weapon technology were as accessible for use in providing a public utopia as they were for providing a private utopia. So, the issue of primary concern, namely that of dominance, revolved around the subject of the energy sciences.

Energy

Energy is recognised as the key to all activity on earth. Natural science is the study of the sources and control of natural energy, and social science (theoretically expressed as economics) is the study of the sources and control of social energy. Both are bookkeeping systems based on mathematics. Therefore, mathematics is the primary energy science and the bookkeeper can be king if the public can be kept ignorant of the methodology of the bookkeeping.

All science is merely a means to an end. The means is knowledge. The end is control. Beyond this remains only one issue: Who will be the beneficiary? In 1954 this was the issue of primary concern. Although the so-called "moral issues" were raised, in view of the law of natural selection it was agreed that a nation or world of people who will not use their intelligence are no better than animals who do not have intelligence. Such people are beasts of burden and steaks on the table by choice and consent.

Consequently, in the interest of future world order, peace, and tranquillity, it was decided to wage a private quiet war against the American public with an ultimate objective of permanently shifting the natural and social energy (wealth) of the undisciplined and irresponsible many into the hands of the self-disciplined, responsible, and "worthy" few.

In order to implement this objective, it was necessary to create, secure, and apply new weapons which, as it turned out, were a class of weapons so subtle and sophisticated in their principle of operation and public appearance as to earn for themselves the name of "silent weapons." In conclusion, the objective of economic research, as conducted by the magnates of capital (banking) and the industries of commodities (goods and services), is the establishment of an economy which is totally predictable and which can be manipulated.

In order to achieve this totally predictable economy, the low-class elements of society must be brought under total control, i.e., They must be housebroken, trained, and assigned a yoke and long-term social duties from a very early age, before they have an opportunity to question the propriety of the matter. In order to achieve such conformity, the lower-class family unit must be disintegrated by a process of increasing preoccupation of the parents and the establishment of government-operated day-care centres for the occupationally orphaned children.

The quality of education given to the lower class must be of the poorest sort, so that the moat of ignorance isolating the inferior class from the superior class is and always remains, incomprehensible to the inferior class. With such an initial handicap, even bright lower class individuals have little if any hope of extricating themselves from their assigned lot in life. This form of slavery is essential to maintain some measure of social order, peace, and tranquillity for the ruling upper class.

Descriptive Introduction to the Silent Weapon

Everything which can be expected from an ordinary weapon is also expected from a silent weapon by its creators, but only in its own manner of functioning. It shoots situations, instead of bullets; it's propellant is data processing, instead of the conventional chemical explosion. The power originates from bits of data in a computer, instead of grains of gunpowder inside a gun. The operator is a computer programmer, instead of a military marksman, and the orders are issued by a banking magnate, instead of a military general. It makes no obvious explosive noises, causes no obvious physical or mental injuries, and does not interfere in an obvious way with anyone's daily social life.

However, it makes an unmistakable "noise," causes unmistakable physical and mental damage, and interferes unmistakably with daily social life, that is, in ways which are unmistakable to a trained observer who knows what to look for. The public cannot comprehend this weapon, and therefore cannot believe that they are being attacked and subdued by a weapon. The public might instinctively feel that something is wrong, but because of the technical nature of the silent weapon, they cannot express their feeling in any rational way, or handle the problem with intelligence. Therefore, they do not know how to call for help, nor do they know how to associate with others to defend themselves against it.

When a silent weapon is applied gradually, the public adjusts and adapts to its presence and learns to tolerate its encroachment on their lives until the psychological pressure (applied via economic methods) becomes too great and they crack up. Therefore, in a way, the silent weapon can be considered to be a type of biological weapon. It attacks the vitality, options, and mobility of the individuals of a society by knowing, understanding, manipulating, and attacking their sources of natural and social energy, and their physical, mental, and emotional strengths and weaknesses.

Theoretical Introduction

"Give me control over a nation's currency, and I care not who makes its laws." - Mayer Amschel Rothschild (1743 - 1812). Today's silent weapons technology is an outgrowth of a simple idea discovered, succinctly expressed, and effectively applied by Mr. Mayer Amschel Rothschild. Mr. Rothschild discovered the missing passive component of economic theory known as economic inductance. He, of course, did not think of his discovery in these twentieth century terms, and, to be sure, mathematical analysis had to wait for the Second Industrial Revolution, the rise of the theory of mechanics and electronics, and finally, the invention of the electronic computer before it could be effectively applied in the control of the world economy.

General Energy Concepts

In the study of energy systems, there always appears three elementary concepts. These are:

Potential Energy,
Kinetic Energy, and
Energy Dissipation.

Corresponding to these concepts, there are three idealised, essentially pure physical counterparts called passive components

In the science of physical mechanics, the phenomenon of Potential Energy is associated with a physical property called Elasticity or stiffness, and can be represented by a stretched spring. In electronic science, Potential energy is stored in a capacitor instead of a spring. This property is called Capacitance instead of Elasticity.

In the science of physical mechanics, the phenomenon of Kinetic Energy is associated with a physical property called Inertia or Mass, and can be represented by a mass or a flywheel in motion. In electronic science, Kinetic Energy is stored in an inductor (in a magnetic field) instead of a mass. This property is called Inductance instead of Inertia.

In the science of physical mechanics, the phenomenon of Energy Dissipation is associated with a physical property called Friction or Resistance, and can be represented by a dashpot or other device which converts energy into heat. In electronic science, Energy Dissipation is performed by an element called either a Resistor.

In economics the equivalents of these three energy concepts are:
Economic Capacitance - **Capital** (money, stock/inventory, investments in buildings etc.)
Economic Conductance - **Goods** (production flow coefficients)
Economic Inductance - **Services** (the influence of the industrial population on output)

All of the mathematical theory developed in the study of one energy system (e.g., mechanics, electronics, etc.) can be immediately applied in the study of any other energy system (e.g., economics).

Mr Rothschild's Energy Discovery

What Mr. Rothschild discovered was the basic principle of power, influence, and control over people as applied to economics. That principle is "when you assume the appearance of power, people soon give it to you." Mr. Rothschild had discovered that currency or deposit loan accounts had the required appearance of power that could be used to induce people (inductance, with people corresponding to a magnetic field) into surrendering their real wealth in exchange for a promise of greater wealth (instead of real compensation). They would put up real collateral in exchange for a loan of promissory notes. Mr. Rothschild found that he could issue more notes than he had backing for, provided he had someone's stock of gold to show his customers as a persuader.

Mr. Rothschild loaned his promissory notes to individual and to governments. These would create overconfidence. Then he would make money scarce, tighten control of the system, and collect the collateral through the obligation of contracts. The cycle was then repeated. These pressures could be used to ignite a war. Then he would control the availability of currency to determine who would win the war. Any government which agreed to give him control of its economic system got his support. Collection of debts was guaranteed by economic aid to the enemy of the debtor. The profit derived from this economic methodology made Mr. Rothschild all the more able to expand his wealth. He found that the public greed would allow currency to be printed by government order beyond the limits (inflation) of backing in precious metal or the production of goods and services.

Apparent Capital as "Paper" Inductor

In this structure, credit, presented as a pure element called "currency," has the appearance of capital, but is in effect, negative capital. Hence, it has the appearance of service, but it is, in fact, indebtedness or debt. It is therefore an economic inductance instead of an economic capacitance, and if balanced in no other way, will be balanced by the negation of population (war, genocide). The total sum of goods and services represents real capital and it is called the **Gross National Product**, and currency may be printed up to this level and still represent economic capacitance; but currency printed beyond this level is subtractive, represents the introduction of economic inductance, and so becomes notes of indebtedness.

War is therefore the balancing of the system by killing the true creditors (the public which has been taught to exchange true value for inflated currency) and falling back on whatever is left of the resources of nature and regeneration of those resources. Mr. Rothschild had discovered that currency gave him the power to rearrange the economic structure to his own advantage, to shift economic inductance to those economic positions which would encourage the greatest economic instability and oscillation.

The final key to economic control had to wait until there was sufficient data and high-speed computing equipment to keep close watch on the economic oscillations created by price shocking and excess paper energy credits - paper inductance/inflation.

Breakthrough

The aviation field provided the greatest evolution in economic engineering by way of the mathematical theory of shock testing. In this process, a projectile is fired from an airframe on the ground and the impulse of the recoil is monitored by vibration transducers connected to the airframe and wired to chart recorders. By studying the echoes or reflections of the recoil impulse in the airframe, it is possible to discover critical vibrations in the structure of the airframe which either vibrations of the engine or aeolian vibrations of the wings, or a combination of the two, might reinforce resulting in a resonant self-destruction of the airframe in flight. From the standpoint of engineering, this means that the strengths and weaknesses of the structure of the airframe in terms of vibrational energy can be discovered and manipulated.

Application in Economics

To use this method of airframe shock testing in economic engineering, the prices of commodities are shocked, and the public consumer reaction is monitored. The resulting echoes of the economic shock are interpreted theoretically by computers and the psycho-economic structure of the economy is thus discovered. It is by this process that partial differential and difference matrices are discovered that define the family household and make possible its evaluation as an economic industry (dissipative consumer structure). Then the response of the household to future shocks can be predicted and manipulated, and society becomes a well-regulated animal with its reins under the control of a sophisticated computer-regulated social energy bookkeeping system. Eventually every individual element of the structure comes under computer control through a knowledge of personal preferences, such knowledge guaranteed by computer association of consumer preferences (universal product code - the striped bar codes on packages) with identified consumers (initially identified through the use of a credit card and later through a permanent "tattooed" body number invisible under normal ambient illumination).

The Economic Model

The Harvard Economic Research Project (1948-1952) was an extension of World War II Operations Research. Its purpose was to discover the science of controlling an economy: at first the American economy, and then the world economy. It was felt that with sufficient mathematical foundation and data, it would be nearly as easy to predict and control the trend of an economy as to predict and control the trajectory of a projectile. Such has proven to be the case. Moreover, the economy has been transformed into an accurately targeted guided missile.

The immediate aim of the Harvard project was to discover the economic structure, what forces can change that structure, how the behaviour of the structure can be predicted, and how it can be manipulated. What was needed was a well-organised knowledge of the mathematical structures and interrelationships of investment, production, distribution, and consumption. Briefly, it was discovered that an economy obeyed the same laws as electricity and that all of the mathematical theory and practical and computer know-how developed for the electronic field could be directly applied in the study of economics. This discovery was not openly declared, and its more subtle implications were, and are, kept as a closely guarded secret, for example, in an economic model, human life is measured in dollars, and that the electric spark generated when opening a switch connected to an active inductor is mathematically the same as starting a war.

The greatest hurdle which theoretical economists faced was the accurate description of the household as an industry. This is a challenge because consumer purchases are a matter of choice which in turn is influenced by family income, purchase price, and other economic factors. This hurdle was cleared in an indirect and statistically approximate way by an application of shock testing to determine the current characteristics, called current technical coefficients, of a household industry. Finally, because problems in theoretical electronics can be translated very easily into problems of theoretical economics, and the solution translated back again, it follows that only a book of language translation and concept definition needed to be written for economics. The remainder could be got from standard works on mathematics and electronics. This makes the publication of books on advanced economics unnecessary, and greatly simplifies the silent war project security.

Industrial Diagrams

An ideal industry is defined as a device which receives value from other industries in several forms and converts them into one specific product for sales and distribution to other industries. It has several inputs and one output. What the public normally thinks of as one industry is really an industrial complex, where several industries under one roof produce one or more products.

Three Industrial Classes

Industries fall into three categories or classes by type of output:
Class 1 - **Capital** (resources)
Class 2 - **Goods** (commodities or use - dissipative)
Class 3 - **Services** (action of population).

Class 1 industries exist at three levels:

- (a) Nature - sources of energy and raw materials.
- (b) Government - printing of currency equal to the gross national product (GNP), and extension of currency in excess of GNP.
- (c) Banking - loaning of money for interest, and extension (inflation/counterfeiting) of economic value through deposit loan accounts.

Class 2 industries exist as producers of tangible or consumer (dissipated) products. This sort of activity is usually recognised and labelled by the public as "industry."

Class 3 industries are those which have service rather than a tangible product as their output. These industries are called
(a) Households, and
(b) Governments. Their output is human activity of a mechanical sort, and their basis is population.

Aggregation

The whole economic system can be represented by a three-industry model if one allows the names of the outputs to be:
(1) Capital,
(2) Goods, and
(3) Services.

The problem with this representation is that it would not show the influence of, say, the textile industry on the steel industry. This is because both the textile industry and the steel industry would be contained within a single classification called the "goods industry" and by this process of combining or aggregating these two industries under one system block they would lose their economic individuality.

The E- Model

A national economy consists of simultaneous flows of production, distribution, consumption, and investment. If all of these elements including labour and human functions are assigned a numerical value using common units of measure, say, US dollars at their 1939 value, then this flow can be further represented by a current flow in an electronic circuit, and its behaviour can be predicted and manipulated with useful precision.

The three ideal passive energy components of electronics, the capacitor, the resistor, and the inductor correspond to the three ideal passive energy components of economics called the pure industries of capital, goods, and services.

Economic Capacitance represents the storage of capital in one form or another.

Economic Conductance represents the level of conductance of materials for the production of goods.

Economic Inductance represents the inertia of economic value in motion. This is a population phenomenon known as services.

Economic Inductance

An electrical inductor (e.g., a coil or wire) has an electric current as its primary phenomenon and a magnetic field as its secondary phenomenon (inertia). Corresponding to this, an economic inductor has a flow of economic value as its primary phenomenon and a population field as its secondary field phenomenon of inertia. When the flow of economic value (e.g., money) diminishes, the human population field collapses in order to keep the economic value (money) flowing (extreme case - war). This public inertia is a result of consumer buying habits, expected standard of living, etc., and is generally a phenomenon of self-preservation.

Inductive Factors to Consider

(1) Population
(2) Magnitude of the economic activities of the government
(3) The method of financing these government activities
    (See Peter-Paul Principle - inflation of the currency.)

Translation

(a few examples will be given.)
Charge - coulombs - dollars (1939).
Current Flow - amperes (coulombs per second) - dollars of flow per year.
Motivating Force - volts - dollars (output) demand.
Conductance - amperes per volt - dollars of flow per year per dollar demand.
Capacitance - coulombs per volt - dollars of production inventory/stock per dollar demand.

Time-Flow Relationships and Self-Destructive Oscillations

An ideal industry may be symbolised electronically in various ways. The simplest way is to represent a demand by a voltage and a supply by a current. When this is done, the relationship between the two becomes what is called an admittance, which can result from three economic factors:

(1) **Hindsight flow**,
(2) **Present flow**, and
(3) **Foresight flow**.

Foresight flow is the result of that property of living entities to cause energy (food) to be stored for a period of low energy (e.g., a winter season). It consists of demands made upon an economic system for that period of low energy (winter season). In a production industry it takes several forms, one of which is known as production stock or inventory. In electronic symbology this specific industry demand (a pure capital industry) is represented by capacitance and the stock or resource is represented by a stored charge. Satisfaction of an industry demand suffers a lag because of the loading effect of inventory priorities.

Present flow ideally involves no delays. It is, so to speak, input today for output today, a "hand to mouth" flow. In electronic symbology, this specific industry demand is represented by a conductance which is then a simple economic valve (a dissipative element).

Hindsight flow is known as habit or inertia. In electronics this phenomenon is the characteristic of an inductor (economic analogue = a pure service industry) in which a current flow (economic analogue = flow of money) creates a magnetic field (economic analogue = active human population) which, if the current (money flow) begins to diminish, will collapse (war) to maintain the current (flow of money - energy).

Other large alternatives to war as economic inductors or economic flywheels are an open-ended social welfare program, or an enormous (but fruitful) open-ended space program. The problem with stabilising the economic system is that there is too much demand on account of:
(1) Too much greed and
(2) Too much population.
This creates excessive economic inductance which can only be balanced with economic capacitance (true resources or value - e.g., in goods or services).

The social welfare program is nothing more than an open-ended credit balance system which creates a false capital industry to give non-productive people a roof over their heads and food in their stomachs. This can be useful, however, because the recipients become state property in return for the "gift," and form a standing army for the Elite - as he who pays the piper picks the tune. Those who get hooked on the economic drug, must go to the Elite for a fix. In this, the method of introducing large amounts of stabilising capacitance is by borrowing on the future "credit" of the world. This is a fourth law of motion - **onset**, and consists of performing an action and leaving the system before the reflected reaction returns to the point of action - a delayed reaction.

The means of surviving the reaction is by changing the system before the reaction can return. By this means, politicians become more popular in their own time and the public pays later. In fact, the measure of such a politician is the delay time. The same thing is achieved by a government by printing money beyond the limit of the gross national product, and economic process called inflation. This puts a large quantity of money into the hands of the public and maintains a balance against their greed, creates a false self-confidence in them and, for a while, stays the wolf from the door.

They must eventually resort to war to balance the account, because war ultimately is merely the act of destroying the creditor, and the politicians are the publicly hired hit men that justify the act to keep the responsibility and blood off the public conscience. If the people really cared about their fellow man, they would control their appetites (greed, procreation, etc.) so that they would not have to operate on a credit or welfare social system which steals from the worker to satisfy the bum. Since most of the general public will not exercise restraint, there are only two alternatives to reduce the economic inductance of the system.

(1) Let the populace bludgeon each other to death in war, which will only result in a total destruction of the living earth.

(2) Take control of the world by the use of economic "silent weapons" in a form of "quiet warfare" and reduce the economic inductance of the world to a safe level by a process of benevolent slavery and genocide.

The latter option has been taken as the obviously better option. At this point it should be crystal clear to the reader why absolute secrecy about the silent weapons is necessary. The general public refuses to improve its own mentality and its faith in its fellow man. It has become a herd of proliferating barbarians, and, so to speak, a blight upon the face of the earth. They do not care enough about economic science to learn why they have not been able to avoid war despite religious morality, and their religious or self-gratifying refusal to deal with earthly problems, places the solution of the earthly problem beyond their reach.

It is left to those few who are truly willing to think and survive, as the fittest to survive, to solve the problem for themselves as the few who really care. Otherwise, exposure of the silent weapon would destroy our only hope of preserving the seed of the future true humanity.

The Household Industry

The industries of finance (banking), manufacturing, and government, real counterparts of the pure industries of capital, goods, and services, are easily defined because they are generally logically structured. Because of this their processes can be described mathematically and their technical coefficients can be easily deduced. This, however, is not the case with the service industry known as the household industry.

Household Models

The problem which a theoretical economist faces is that the consumer preferences of any household are not easily predictable and the technical coefficients of any one household tend to be a non-linear, very complex, and variable function of income, prices, etc. Computer information derived from the use of the universal product code in conjunction with credit-card purchase as an individual household identifier, could change this state of affairs, but the Universal Product Code method is not yet available on a national or even a significant regional scale. To compensate for this data deficiency, an alternate indirect approach of analysis has been adopted known as economic shock testing. This method, widely used in the aircraft manufacturing industry, develops an aggregate statistical sort of data.

Applied to economics, this means that all of the households in one region or in the whole nation are studied as a group or class rather than individually, and the mass behaviour rather than the individual behaviour is used to discover useful estimates of the technical coefficients governing the economic structure of the hypothetical single-household industry. One method of evaluating the technical coefficients of the household industry depends upon shocking the prices of a commodity and noting the changes in the sales of all of the commodities.

Economic Shock Testing

In recent times, the application of Operations Research to the study of the public economy has been obvious for anyone who understands the principles of shock testing. In the shock testing of an aircraft airframe, the recoil impulse of firing a gun mounted on that airframe causes shock waves in that structure which tell aviation engineers the conditions under which some parts of the airplane or the whole airplane or its wings will start to vibrate or flutter like a guitar string, a flute reed, or a tuning fork, and disintegrate or fall apart in flight. Economic engineers achieve the same result in studying the behaviour of the economy and the consumer public by carefully selecting a staple commodity such as beef, coffee, gasoline, or sugar, and then causing a sudden change or shock in its price or availability, thus kicking everybody's budget and buying habits out of shape. They then observe the shock waves which result by monitoring the changes in advertising, prices, and sales of that and other commodities.

The objective of such studies is to acquire the know-how to set the public economy into a predictable state of motion or change, even a controlled self-destructive state of motion which will convince the public that certain "expert" people should take control of the money system and re-establish security (rather than liberty and justice) for all. When the subject citizens are rendered unable to control their financial affairs, they, of course, become totally enslaved, and a source of cheap labour. Not only the prices of commodities, but also the availability of labour can be used as the means of shock testing. Labour strikes deliver excellent tests shocks to an economy, especially in the critical service areas of trucking (transportation) , communication, public utilities (energy, water, garbage collection), etc. By shock testing, it is found that there is a direct relationship between the availability of money flowing in an economy and the real psychological outlook and response of masses of people dependent upon that availability. For example, there is a measurable quantitative relationship between the price of gasoline and the probability that a person would experience a headache, feel a need to watch a violent movie, smoke a cigarette, or go to a tavern for a mug of beer.

It is most interesting that, by observing and measuring the economic models by which the public tries to run from their problems and escape from reality, and by applying the mathematical theory of Operations Research, it is possible to program computers to predict the most probable combination of created events (shocks) which will bring about a complete control and subjugation of the public through a subversion of the public economy (by shaking the plum tree).

Introduction to Economic Amplifiers

Economic Amplifiers are the active components of economic engineering. The basic characteristic of any amplifier (mechanical, electrical, or economic) is that it receives an input control signal and delivers energy from an independent energy source to a specified output terminal in a predictable relationship to that input control signal. The simplest form of an economic amplifier is a device called advertising. If a person is spoken to by a T.V. advertiser as if he were a twelve-year-old, then, due to suggestibility, he will, with a certain probability, respond or react to that suggestion with the uncritical response of a twelve-year-old and will reach into his economic reservoir and deliver its energy to buy that product on impulse when he passes it in the store.

An Economic Amplifier may have several inputs and output. Its response might be instantaneous or delayed. Its circuit symbol might be a rotary switch if its options are exclusive, qualitative, "go" or "no-go", or it might have its parametric input/output relationships specified by a matrix with internal energy sources represented. Whatever its form might be, its purpose is to govern the flow of energy from a source to an output sink in direct relationship to an input control signal. For this reason, it is called an active circuit element or component. Economic Amplifiers fall into classes called strategies, and, in comparison with electronic amplifiers, the specific internal functions of an economic amplifier are called logistical instead of electrical. Therefore, economic amplifiers not only deliver power gain but also, in effect, are used to cause changes in the economic circuitry.

In the design of an economic amplifier we must have some idea of at least five functions ,which are:

(1) The available input signals,
(2) The desired output-control objectives,
(3) The strategic objective,
(4) The available economic power sources,
(5) The logistical options.

The process of defining and evaluating these factors and incorporating the economic amplifier into an economic system has been popularly called "game theory". The design of an economic amplifier begins with a specification of the power level of the output, which can range from personal to national. The second condition is accuracy of response, i.e., how accurately the output action is a function of the input commands. High gain combined with strong feedback helps to deliver the required precision. Most of the error will be in the input data signal. Personal input data tends to be specified, while national input data tends to be statistical.

Short List of Inputs

General sources of information:
(1) Telephone taps
(2) Surveillance
(3) Analysis of garbage
(4) Behaviour of children in school

Standard of living by:
(1) Food
(2) Clothing
(3) Shelter
(4) Transportation

Social contacts:
(1) Telephone - itemized record of calls
(2) Family - marriage certificates, birth certificates, etc.
(3) Friends, associates, etc.
(4) Memberships in organizations
(5) Political affiliation

The Personal Paper Trail

Personal buying habits, i.e., personal consumer preferences:
(1) Bank accounts
(2) Credit-card purchases
(3) "Tagged" credit-card purchases - those with a Universal Product Code

Assets:
(1) Bank accounts
(2) Savings accounts
(3) Property
(4) Business
(5) Vehicles, etc.
(6) Safety deposit at a bank
(7) Stock market purchases

Liabilities:
(1) Creditors
(2) Enemies (see - legal)
(3) Loans
(4) Consumer credit

Government sources (ploys)*:
(1) Welfare
(2) Social Security
(3) U.S.D.A. surplus food
(4) Dole
(5) Grants
(6) Subsidies

*Principle of this ploy - the citizen will almost always make the collection of information easy if he can operate on the "free sandwich principle" of "eat now, and pay later."

Government sources (via intimidation) :
(1) Internal Revenue Service
(2) OSHA
(3) Census
(4) etc.

Other government sources - surveillance of U.S. mail.

Habit Patterns - Programming

Strengths and weaknesses:
(1) Activities (sports, hobbies, etc.)
(2) See "legal" (fear, anger, etc. - crime record)
(3) Hospital records (drug sensitivities, reaction to pain, etc.)
(4) Psychiatric records (fears, angers, disgusts, adaptability, reactions to stimuli, violence, suggestibility or hypnosis, pain, pleasure, love, and sex)

Methods of coping - of adaptability - behaviour:
(1) Consumption of alcohol
(2) Consumption of drugs
(3) Entertainment
(4) Religious factors influencing behaviour
(5) Other methods of escaping from reality

Payment modus operandi (MO) - pay on time, etc.:
(1) Payment of telephone bills
(2) Energy purchases (electrical, gas,...)
(3) Water purchases
(4) Repayment of loans
(5) House payments
(6) Vehicle payments
(7) Payments on credit cards

Political sensitivity:
(1) Beliefs
(2) Contacts
(3) Position
(4) Strengths/weaknesses
(5) Projects/activities

Legal inputs - behavioural control (Excuses for investigation, search, arrest, or use of force to modify behaviour):
(1) Court records
(2) Police records - NCIC
(3) Driving record
(4) Reports made to police
(5) Insurance information
(6) Anti-establishment acquaintances

National Input Information

Business sources (via I.R.S., etc.):
(1) Prices of commodities
(2) Sales
(3) Investments in
  (a) stocks/inventory
  (b) production tools and machinery
  (c) buildings and improvements
  (d) the stock market

Banks and credit bureaus:
(1) Credit information
(2) Payment information

Miscellaneous sources:
(1) Polls and surveys
(2) Publications
(3) Telephone records
(4) Energy and utility purchases

Short List of Inputs
Outputs - create controlled situations - manipulation of the economy, hence society - control of compensation and income.

Sequence:
(1) Allocates opportunities.
(2) Destroys opportunities.
(3) Controls the economic environment.
(4) Controls the availability of raw materials.
(5) Controls capital.
(6) Controls bank rates.
(7) Controls the inflation of the currency.
(8) Controls the possession of property.
(9) Controls industrial capacity.

(10) Controls manufacturing.
(11) Controls the availability of goods (commodities) .
(12) Controls the prices of commodities.
(13) Controls services, the labour force, etc.
(14) Controls payments to government officials
(15) Controls the legal functions.
(16) Controls the personal data files - uncorrectable by the party slandered.
(17) Controls advertising.
(18) Controls media contact.
(19) Controls material available for T.V. viewing.
(20) Disengages attention from real issues.
(21) Engages emotions.
(22) Creates disorder, chaos, and insanity.
(23) Controls design of more probing tax forms.
(24) Controls surveillance.
(25) Controls the storage of information.
(26) Develops psychological analyses and profiles of individuals.
(27) Controls sociological factors.
(28) Controls health options.
(29) Preys on weakness.
(30) cripples strengths.
(31) leaches wealth and substance.

Table of Strategies

Do This	To Get This
Keep the public ignorant	Less public organisation
Maintain access control	Required reaction to output (prices, sales)
Create preoccupation	Lower defences
Attack the family unit	Control the education of the young
Give less cash and more credit and dole	More self-indulgence and more data
Attack the privacy of the church	Destroy faith in this sort of government
Social conformity	Computer programming simplicity
Minimise tax protests	Maximum economic data, minimum enforcement problems
Stabilise the consent	Simplicity coefficients
Tighten control of variables	Simpler computer input data - greater predictability
Establish boundary conditions	Problem simplicity / solutions of differential and difference equations
Proper timing	Less data shift and blurring
Maximise control	Minimum resistance to control
Collapse of currency	Destroy the faith of the American people in each other

Diversion, the Primary Strategy

Experience has shown that the simplest method of securing a silent weapon and gaining control of the public is to keep the public undisciplined and ignorant of the basic system principles on the one hand, while keeping them confused, disorganised, and distracted with matters of no real importance on the other hand. This is achieved by:

(1) Disengaging their minds; sabotaging their mental activities; providing a low-quality program of public education in mathematics, logic, systems design and economics; and discouraging technical creativity.

(2) Engaging their emotions, increasing their self-indulgence and their indulgence in emotional and physical activities, by:

(a) Unrelenting emotional affronts and attacks (mental and emotional rape) by way of constant barrage of sex, violence, and wars in the media - especially the T.V. and the newspapers.

(b) Giving them what they desire - in excess - "junk food for thought" - and depriving them of what they really need.

(3) Rewriting history and law and subjecting the public to the deviant creation, thus being able to shift their thinking from personal needs to highly fabricated outside priorities.

These preclude their interest in, and discovery of, the silent weapons of social automation technology. The general rule is that there is a profit in confusion; the more confusion, the more profit. Therefore, the best approach is to create problems and then offer solutions.

Diversion Summary

Media: Keep the adult public attention away from the real social issues, and captivated by matters of no real importance.

Schools: Keep the young public ignorant of real mathematics, real economics, real law, and real history.

Entertainment: Keep the public entertainment below a sixth-grade (12 year old) level.

Work: Keep the public busy, busy, busy, with no time to think; back on the farm with the other animals.

Consent, the Primary Victory

A silent weapon system operates upon data obtained from a docile public by legal (but not always lawful) force. Much information is made available to silent weapon systems programmers through the Internal Revenue Service. (See Studies in the Structure of the American Economy for an I.R.S. source list). This information consists of the enforced delivery of well-organised data contained in federal and state tax forms, collected, assembled, and submitted by slave labour provided by taxpayers and employers. Furthermore, the number of such forms submitted to the I.R.S. is a useful indicator of public consent, an important factor in strategic decision making. Other data sources are given in the Short List of Inputs.

Consent Coefficients - numerical feedback indicating victory status. Psychological basis: When the government is able to collect tax and seize private property without just compensation, it is an indication that the public is ripe for surrender and is consenting to enslavement and legal encroachment. A good and easily quantified indicator of harvest time is the number of public citizens who pay income tax despite an obvious lack of reciprocal or honest service from the government.

Amplification Energy Sources

The next step in the process of designing an Economic Amplifier is discovering the energy sources. The energy sources which support any primitive economic system are, of course, a supply of raw materials, and the consent of the people to labour and consequently assume a certain rank, position, level, or class in the social structure, i.e., to provide labour at various levels in the pecking order. Each class, in guaranteeing its own level of income, controls the class immediately below it, hence preserves the class structure. This provides stability and security, but also government from the top. As time goes on and communication and education improve, the lower-class elements of the social labour structure become knowledgeable and envious of the good things that the upper-class members have. They also begin to attain a knowledge of energy systems and the ability to enforce their rise through the class structure. This threatens the sovereignty of the Elite.

If this rise of the lower classes can be postponed long enough, the Elite can achieve energy dominance, and labour by consent no longer will hold a position of an essential energy source. Until such energy dominance is absolutely established, the consent of people to labour and let others handle their affairs must be taken into consideration, since failure to do so could cause the people to interfere in the final transfer of energy sources to the control of the Elite. It is essential to recognise that at this time, public consent is still an essential key to the release of energy in the process of economic amplification. Therefore, consent as an energy release mechanism will now be considered.

Logistics

The successful application of a strategy requires a careful study of inputs, outputs, the strategy connecting the inputs and the outputs, and the available energy sources to fuel the strategy. This study is called "Logistics". A logistical problem is studied at the elementary level first, and then levels of greater complexity are studied as a synthesis of elementary factors. This means that a given system is analysed, i.e., broken down into its sub-systems, and these in turn are analysed, until by this process, one arrives at the logistical "atom," the individual.

The Artificial Womb

From the time a person leaves his mother's womb, his every effort is directed towards building, maintaining, and withdrawing into artificial wombs, various sorts of substitute protective devices or shells. The objective of these artificial wombs is to provide a stable environment for both stable and unstable activity; to provide a shelter for the evolutionary processes of growth and maturity - i.e., survival; to provide security for freedom and to provide defensive protection for offensive activity. This is equally true of both the general public and the Elite. However, there is a definite difference in the way each of these classes go about the solution of problems

The Political Structure of a Nation – Dependency

The primary reason why the individual citizens of a country create a political structure is a subconscious wish or desire to perpetuate their own dependency relationship of childhood. Simply put, they want a human god to eliminate all risk from their life, pat them on the head, kiss their bruises, put a chicken on every dinner table, clothe their bodies, tuck them into bed at night, and tell them that everything will be all right when they wake up in the morning. This public demand is incredible, so the human god, the politician, meets incredibility with incredibility by promising the world and delivering nothing. So who is the bigger liar? The public? or The "godfather"? This public behaviour is surrender born of fear, laziness, and expediency. It is the basis of the welfare state as a strategic weapon, useful against a disgusting public.

Action / Offence

Most people want to be able to subdue and/or kill other human beings who disturb their daily lives, but they do not want to have to cope with the moral and religious issues which such an overt act on their part might raise. Therefore, they assign the dirty work to others (including their own children) so as to keep the blood off their hands. They rave about the humane treatment of animals and then sit down to a delicious hamburger from a whitewashed slaughterhouse down the street and out of sight. But even more hypocritical, they pay taxes to finance a professional association of hit men collectively called politicians, and then complain about corruption in government.

Responsibility

Again, most people want to be free to do the things (to explore, etc.) but they are afraid of failing. The fear of failure is manifested in irresponsibility, and especially in delegating those personal responsibilities to others where success is uncertain or carries possible or created liabilities (law) which the person is not prepared to accept. They want authority (root word - "author"), but they will not accept responsibility or liability. So they hire politicians to face reality for them.

Summary

The people hire the politicians so that the people can:
(1) Obtain security without managing it.
(2) Obtain action without thinking about it.
(3) Inflict theft, injury, and death upon others without having to contemplate either life or death.
(4) Avoid responsibility for their own intentions.
(5) Obtain the benefits of reality and science without exerting themselves or learning either of these things.

They give the politicians the power to create and manage a war machine:
(1) Provide for the survival of the nation/womb.
(2) Prevent encroachment of anything upon the nation/womb.
(3) Destroy the enemy who threatens the nation/womb.
(4) For the sake of stability of the nation/womb, destroy those citizens of their own country who do not conform.

Politicians hold many quasi-military jobs, the lowest being the police who are soldiers, the attorneys and C.P.A.s next who are spies and saboteurs (licensed), and the judges who shout orders and run the closed union military shop for whatever the market will bear. The generals are industrialists. The "presidential" level of commander-in- chief is shared by the international bankers. The people know that they have created this farce and financed it with their own taxes (consent), but they would rather knuckle under than be the hypocrite. Thus, a nation becomes divided into two very distinct parts, a docile sub-nation [great silent majority] and a political sub-nation. The political sub-nation remains attached to the docile sub-nation, tolerates it, and leaches its substance until it grows strong enough to detach itself and then devour its parent.

System Analysis

In order to make meaningful computerized economic decisions about war, the primary economic flywheel, it is necessary to assign concrete logistical values to each element of the war structure - personnel and material alike. This process begins with a clear and candid description of the subsystems of such a structure.

The Draft (military service)

Few efforts of human behaviour modification are more remarkable or more effective than that of the socio-military institution known as the draft. A primary purpose of a draft or other such institution is to instil, by intimidation, in the young males of a society the uncritical conviction that the government is omnipotent. He is soon taught that a prayer is slow to reverse what a bullet can do in an instant. Thus, a man trained in a religious environment for eighteen years of his life can, by this instrument of the government, be broken down, be purged of his fantasies and delusions in a matter of mere months. Once that conviction is instilled, all else becomes easy to instil.

Even more interesting is the process by which a young man's parents, who purportedly love him, can be induced to send him off to war to his death. Although the scope of this work will not allow this matter to be expanded in full detail, nevertheless, a coarse overview will be possible and can serve to reveal those factors which must be included in some numerical form in a computer analysis of social and war systems. We begin with a tentative definition of the draft. The draft (selective service, etc.) is an institution of compulsory collective sacrifice and slavery, devised by the middle-aged and elderly for the purpose of pressing the young into doing the public dirty work. It further serves to make the youth as guilty as the elders, thus making criticism of the elders by the youth less likely (Generational Stabilizer). It is marketed and sold to the public under the label of "patriotic = national" service.

Once a candid economic definition of the draft is achieved, that definition is used to outline the boundaries of a structure called a Human Value System, which in turn is translated into the terms of game theory. The value of such a slave labourer is given in a Table of Human Values, a table broken down into categories by intellect, experience, post-service job demand, etc. Some of these categories are ordinary and can be tentatively evaluated in terms of the value of certain jobs for which a known fee exists. Some jobs are harder to value because they are unique to the demands of social subversion, for an extreme example: the value of a mother's instruction to her daughter, causing that daughter to put certain behavioural demands upon a future husband ten or fifteen years hence; thus, by suppressing his resistance to a perversion of a government, making it easier for a banking cartel to buy the State of New York in, say, twenty years.

Such a problem leans heavily upon the observations and data of wartime espionage and many types of psychological testing. But crude mathematical models (algorithms, etc.) can be devised, if not to predict, at least to predetermine these events with maximum certainty. What does not exist by natural cooperation is thus enhanced by calculated compulsion. Human beings are machines, levers which may be grasped and turned, and there is little real difference between automating a society and automating a shoe factory. These derived values are variable. (It is necessary to use a current Table of Human Values for computer analysis). These values are given in true measure rather than U.S. dollars, since the latter is unstable, being presently inflated beyond the production of national goods and services so as to give the economy a false kinetic energy ("paper" inductance). The silver value is stable, it being possible to buy the same amount with a gram of silver today as it could be bought in 1920. Human value measured in silver units changes slightly due to changes in production technology.

Factor 1 – Enforcement

As in every social system approach, stability is achieved only by understanding and accounting for human nature (action/reaction patterns). A failure to do so can be, and usually is, disastrous. As in other human social schemes, one form or another of intimidation (or incentive) is essential to the success of the draft. Physical principles of action and reaction must be applied to both internal and external subsystems. To secure the draft, individual brainwashing/programming and both the family unit and the peer group must be engaged and brought under control.

Factor 2 – Father

The man of the household must be housebroken to ensure that junior will grow up with the right social training and attitudes. The advertising media, etc., are engaged to see to it that father-to-be is pussy-whipped before or by the time he is married. He is taught that he either conforms to the social notch cut out for him or his sex life will be hobbled and his tender companionship will be zero. He is made to see that women demand security more than logical, principled, or honourable behaviour. By the time his son must go to war, father (with jelly for a backbone) will slam a gun into junior's hand before father will risk the censure of his peers, or make a hypocrite of himself by crossing the investment he has in his own personal opinion or self-esteem. Junior will go to war or father will be embarrassed. So junior will go to war, the true purpose not withstanding.

Factor 3 – Mother

The female element of human society is ruled by emotion first and logic second. In the battle between logic and imagination, imagination always wins, fantasy prevails, maternal instinct dominates so that the child comes first and the future comes second. A woman with a newborn baby is too starry-eyed to see her child as a wealthy man's cannon fodder or a cheap source of slave labour. A woman must, however, be conditioned to accept the transition to "reality" when it comes, or even sooner. As the transition becomes more difficult to manage, the family unit must be carefully disintegrated, and state-controlled public education and state-operated child-care centres must be become more common and legally enforced so as to begin the detachment of the child from the mother and father at an earlier age. Inoculation of behavioural drugs [Ritalin] can speed the transition for the child (mandatory). Caution: A woman's impulsive anger can override her fear. An irate woman's power must never be underestimated, and her power over a pussy-whipped husband must likewise never be underestimated. It got women the vote in 1920.

Factor 4 – Junior

The emotional pressure for self-preservation during the time of war and the self-serving attitude of the common herd that have an option to avoid the battlefield - if junior can be persuaded to go - is all of the pressure finally necessary to propel Johnny off to war. Their quiet blackmailing of him are the threats: "No sacrifice, no friends; no glory, no girlfriends".

Factor 5 – Sister

And what about junior's sister? She is given all the good things of life by her father, and taught to expect the same from her future husband regardless of the price.

Factor 6 – Cattle

Those who will not use their brains are no better off than those who have no brains, and so this mindless school of jelly-fish, father, mother, son, and daughter, become useful beasts of burden or trainers of the same.

Please note that the section of text above, shown in blue, is not an expression of my own personal opinion, but comes from an anonymous document. However, sections of it describe clearly what is without question being applied to the people in many nations of the world today, so it is difficult to discount any of what is said. At the present time, economic warfare is most definitely being waged against normal, innocent people in most countries of the world, and there is every appearance that a major offensive against us is in progress, instigated and orchestrated by the few "Elite" New World Order people who have already caused so much unnecessary death and suffering.

So who are the New World Order people whose aims are to disadvantage and destroy ordinary people through their "Quiet War"? Well, there are several major branches of them, each presenting a benign and caring face to the world and most with large numbers of sincere adherents who have not the slightest idea of the aims and policies of the few people at the top who actually direct and control those organisations. While most operations are carried out in complete secrecy, the most visible people in the ruling bodies form the Bilderberg Group. This comprises 13 Freemasons, 13 Vatican representatives, and 13 Black Mobility people. These 39 people of the Bilderberg Group have offices in Switzerland (the only European country which was never invaded or bombed during World War One or World War Two) answer to the 13 people who form the Policy Group, which in turn answers to the 9 people of the Round Table. The individuals concerned are typically, powerful financiers, industrialists, statesmen and intellectuals.

The power and influence of these people should not be underestimated. They have infiltrated and subverted the US Congress and Senate, rendering ineffective the checks and balances intended when the Constitution was originally set up. At 3:30 am on Saturday 4th August 1990, a minority of US Senators, maybe ten at most, passed the Senate Intelligence Authorisation Act for Fiscal Year 1991 (S.B. 2834). This bill is not widely known. It was brought to a vote by Senator Sam Nunn in the dead of night when the opposition was gone. It effectively transfers most authority of the United States Government directly into the hands of the President. It gives him the power to initiate war, appropriate public funds, define foreign policy goals, and decide what is important to US national security. It gives the President the power to initiate covert actions (a power never before given to any President) and prevents Congress from stopping the President's initiation of covert actions. It allows the President to use any federal "departments, agencies or entities" to operate or finance a covert operation. It empowers the President to use any other nation or private contractor or person to fund or operate a covert action. It redefines covert actions as operations "necessary to support foreign policy objectives of the United States" which is a definition which is so broad and vague as to be essentially unlimited. It, for the first time ever, officially claims the right of the United States to interfere secretly in the internal "political, economic or military affairs" of other countries in direct and flagrant violation of international law. It requires the President to prepare and deliver a written finding to the Intelligence committees of Congress, but it allows the President to omit "extremely sensitive matters" and authorises the President to claim Executive Privilege if Congress asks too many questions.

Further, there are no penalties in the Bill for violating any of its provisions, including the provision for requiring a finding. That Bill effectively handed all the powers of government to the President, effectively making him the sole ruler of the USA without accountability to anyone.

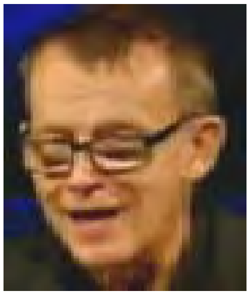
I suggest that the New World Order people have sufficient influence to ensure that every candidate for President of the USA is a member of the New World Order. That way, they are assured that they have full control of the whole of the USA at all times no matter what the outcome of the "democratic" voting. It is said that Henry Ford stated that customers could have a new Model T car in any colour they wanted, provided that the colour was black. Well, the equivalent is now in place, where the American people can have any President they want, provided that the President is a New World Order man. This information is not even considered secret any more. For example:

"... Some even believe we (the Rockefellers) are part of a secret cabal working against the best interests of the United States, characterising my family and me as 'internationalists' and of conspiring with others around the world to build a more integrated global political and economic structure - one world, if you will. If that's the charge, I stand guilty, and I am proud of it. "

—David Rockefeller, Memoirs (2002, Random House publishers), page 405

It should not be imagined that the events in the USA have no effect elsewhere. The New World Order people are working on expanding the EU, blurring the identities of individual countries through legislation, reducing the effects of borders and generally moving towards a single entity with one central government. They are actually aimed at producing ten unified areas of the world which they then intend to amalgamate into a single world state governed by them. This is judged to be easier if there are fewer people, so one of their major aims is to reduce the number of people living at the present time. They also need the remaining people to be wholly dependent on them for the essentials of life, which is one reason why they oppose the introduction of any free-energy device, since having an independent source of power would put people outside their direct control and so will not be allowed.

If the video has not been wiped off the web, then the video from Walter Burien: http://www.youtube.com/watch?v=r5XbvCRHYIk demonstrates the double-bookkeeping which is being operated by the US government where the US people are being told that they are in debt when in fact, “public” funds are massively in profit. In Britain, and probably in many other places in the world, nearly 80% of all earned income is taken away from ordinary people. Natural rights are being done away with and replaced by “privileges” which can be revoked. It has been remarked with considerable insight, that “in the old days, slaves were housed and fed, but today, those slaves are expected to house and feed themselves”. For a simple straightforward explanation of how this is done, try http://www.yourstrawman.com.



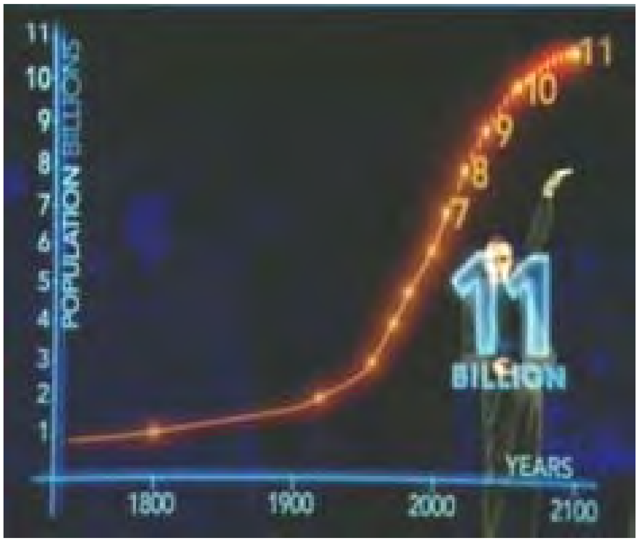
World Population

Recently, an excellent video presentation has been made by the very competent Swedish Prof. Hans Rosling, examining population growth around the world, family size, economic status, personal aspirations and likely future trends around the world.

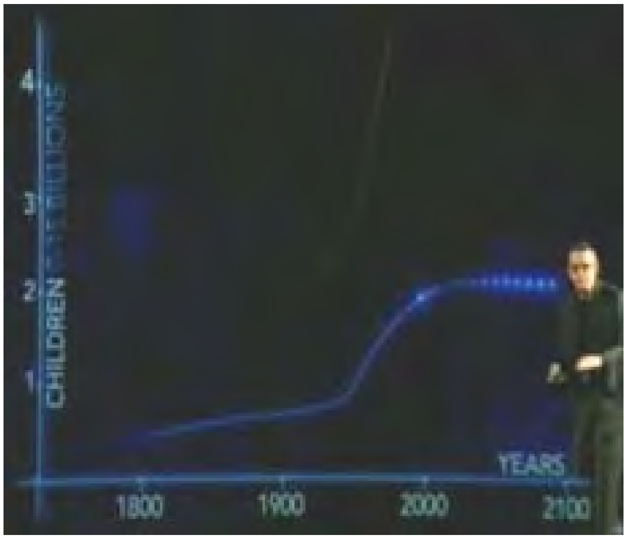
He points out that world population reached 1 billion in the year 1800, and population growth which had been minimal up to then, due to family deaths running at four people in a family of six, reinforced by the fact that average lifespans in those early years being very low. World population reached 2 billion in little more than 100 years afterwards due to the Industrial Revolution. He states that when he was at school, it was 3 billion and at that time, experts said that the planet just could not support so many people. However, contrary to those opinions, in his lifetime it has more than doubled to 7 billion, which he displays graphically like this:

He takes Bangladesh as a particularly severe case. There, during his lifetime, the population has tripled from 50 million to 150 million, but there has already been a major change in lifestyles and attitudes. In 1972 there were on average, 7 babies per woman and the baby's lifespan averaged at just 50 years. That has now dropped to just 2.2 children and the lifespan is now 70 years. In addition, the government now pays parents to keep their children in school longer so that they get a much better education and have far greater opportunity to get well-paid jobs. In just 40 years, Bangladesh has made spectacular progress, but it is not alone in that. In 1963 the average number of babies per woman world wide was 5 while in 2012 that had fallen to just 2.5 and is still decreasing. This change is also not related in any way to religion as every religion has 2-child families as the most common family unit. Child survival is a key factor because if it is almost certain that one or more children will die before the age of five, then parents have more children to allow for that near certainty. The rapid increase in population size which became very noticeable in 1963 was because the average number of children per woman was five, but only one of those five did not reach adulthood, while not long before that, the average number of children per woman was six but, tragically, four of those six died at an early age. Child mortality rate is a critical factor.

The best projections available for the future are that the world population will continue to increase, primarily due to better health care and will continue to rise steadily to about 11 billion, and around the end of this century, will level off around 11 billion. This increase is due to the present population growing older and staying healthy, rather than an increasing number of babies. Actually, the number of babies in the world stabilised around the year 2000 at about 2 billion and is staying steady at that level. Prof. Rosling, who knows a great deal more about this than I do, sees this as the key factor for population zero-growth rate. Personally, I would have thought that the ratio between births and deaths on average world wide was the key factor, but Prof. Rosling certainly seems to know exactly what he is talking about and he displays what he considers to be a reliable estimate of future population growth like this:



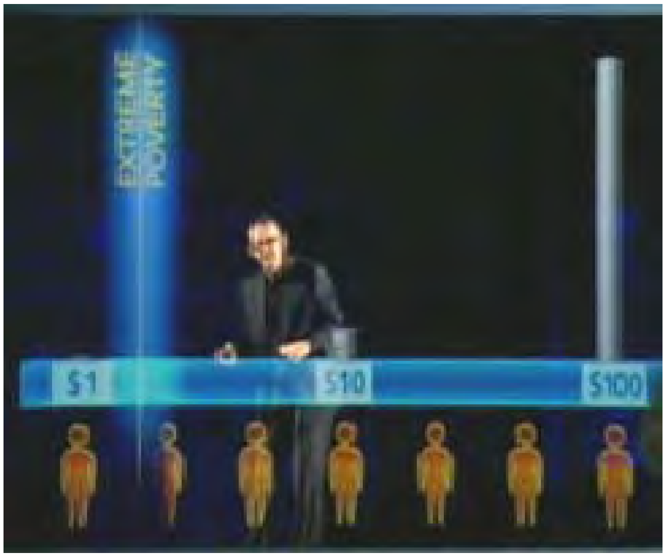
And showing the flattening of the graph for child population in more detail:



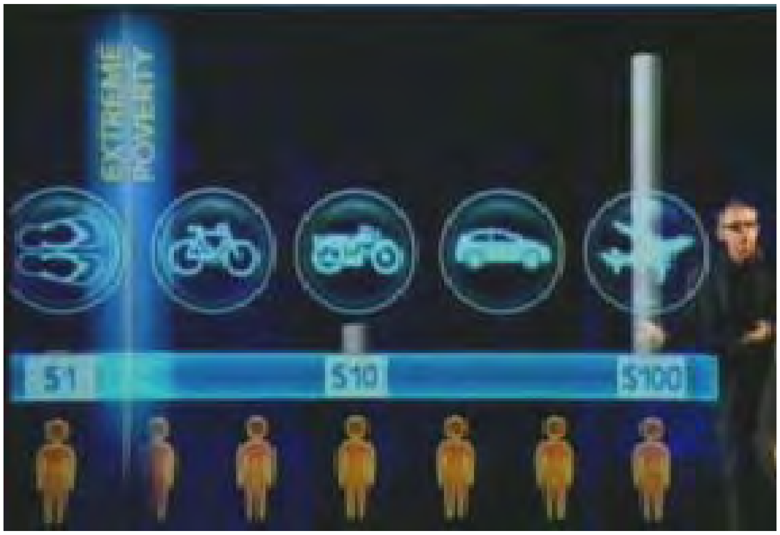
The prediction is for child numbers to remain around 2 billion right through to the end of this century. The overall increase in population growth is caused by young people living today and who survive to old age. The location of people in the world is also important. At the present time, in approximate figures, some 14% of world population is located in America (North and South combined). A further 14% are located in Europe and another 14% in Africa, while the remainder of 58% live in Asia (including Australia and New Zealand).

By the end of this century, it is expected that about 9% will be in America and 9% in Europe, while the population in Africa will have risen to about 36% and in Asia to about 46%. Prof. Rosling expresses the opinion that it is perfectly possible for those levels of population to have a good and prosperous life. He takes Mozambique in Africa as an example as he has personal knowledge of that location, having worked as a medical doctor in that country thirty years ago. The question is, can Africa support a population of 4 billion people and provide all of them with a good life? He states that things have improved immensely in Mozambique even though it is a very poor country. Those born there now have much better conditions with vastly improved medical care, a booming economy and new industries with many new jobs. In common with most of Africa, the biggest improvements are in the towns and cities while the rural areas where most people live have the least improvement, but things are changing there too. In rural areas, most people are farmers, relying on what they grow, for what they eat. These people have needs which you might not suspect. Their first need is for shoes, as they have to walk everywhere, which wastes a great deal of time and requires considerable effort. Their second need is for a bicycle as that allows them to avoid major waste of time in reaching the fields, collecting water and taking large loads to the market and it allows them to search for work and if they get sick, to reach a clinic in time. They have no electricity and farming methods are very basic, causing yields to be far lower than they could be. However, change and improvements are coming, even to the poorest regions of the poorest countries, although progress is slow.

Prof. Rosling then examines the income levels of the present 7 billion people, from the richest to the poorest, illustrating it like this:



Here, it is estimated that the richest billion people average US $100 per day and the poorest billion average just US $1 per day. The economists estimate extreme poverty at just over US $1 per day, defining 'extreme poverty' as not having enough to be sure that you can feed your family. That extreme poverty line divides the second least well-off billion people. To give us a feel for the desires of each billion people, Prof. Rosling illustrates it like this:



Here, the poorest billion people want to get shoes to help with having to walk everywhere. The second and third billion people would find life much easier if each family had a bicycle. The middle billion people want to have a motorcycle, the fifth and sixth billion want a car while the top billion people generally travel by aeroplane. He also points out that the richest people are so much richer than the $100 per day people that the difference is almost as great as the difference between the $1 per day people and the $100 per day people.

However, while we might well tend to think that both the people earning $1 per day and the people earning $10 per day as all of them being poor. But that is very much **not** the case. Earning $10 per day makes a massive difference in quality of life over those people earning just $1 per day. Having a bicycle allows people to reach literacy classes where they can learn to read and write which is a very important step forward. Interestingly, at the present time, more than 80% of people in the world can read and write. Things have improved enormously in the last fifty years. Most countries in Africa today are making steady progress, although we still have more than a billion people in extreme poverty. The United Nations as set the goal of eliminating extreme poverty within twenty years. That can be achieved, mainly by the hard work of those people in need. In that poorest billion people is almost all of the large families, and lack of literacy. Extreme poverty is almost self-creating and so it needs to be ended quickly.

Unfortunately, Prof. Rosling in his excellent presentation entitled "DON'T PANIC the Truth About World Population", now leaves his area of expertise and then discusses the global-warming scam which pretends that human made Carbon Dioxide is responsible for excessive weather conditions, and that is just not the case. The main "global warming gas" is actually water vapour and not carbon dioxide (which is needed by growing crops). Also, of the carbon dioxide produced each year on planet Earth, humans come only a poor third as the vast bulk comes from volcano emissions, the next largest volume comes from insects and animals which outnumber humans by 200,000,000 to one. This notion of human-caused "global warming" is just part of a scam dreamt up to make money by fooling people into paying money when there is absolutely no justification at all. It is complete nonsense, especially so, since the other planets in the solar system are experiencing the same thing, not to mention the fact that global warming and cooling were taking place on Earth long before the Industrial Revolution which is supposed to be causing all this 'extra' carbon dioxide. These scams always rely on the ignorance of most people.

But hold on a minute, this skilful and very well presented programme is being broadcast by the British Broadcasting Corporation (the "BBC") which is a major propaganda outlet for the New World Order. This can be seen quite clearly from the evidence of the BBC's complicit role with the events of 9/11, the BBC reported the collapse of WTC Building 7 on live TV more than 20 minutes before the building actually collapsed. As BBC reporter Jane Standley reported that WTC Building 7 had collapsed, the actual building could still be seen standing intact behind her: http://www.youtube.com/watch?v=ltP2t9nq9fI.

Reporting an unexpected building collapse before it occurred, takes some explaining as to how prior knowledge of the event was in the hands of the BBC. The BBC operates a protection racket called the “TV Licence” scam, where people are threatened and coerced into paying an arbitrarily chosen amount of money to this private commercial company. There is actually, not the slightest doubt about this, a fact which was highlighted by the court case of Mr Rooke who was charged with the “crime” of withholding his TV licence fees, and in February 2013, in Surrey in England, the BBC took Mr Rooke to court. However, once the judge saw the evidence presented by Mr Rooke and his team of experts against the BBC, he had no option but to discharge the conviction. Mr Rooke felt that the BBC’s cover up of this evidence was supporting the true terrorists of 9/11 to get away with their crime. He refused to pay his TV licence fee on the basis of Section 15, Article 3 of the UK Terrorism Act.

This states that it is a crime to provide monetary support to any organisation that engages in or supports terrorist activity. In the opinion of Mr Rooke, by the BBC covering up the evidence about 9/11, they have been aiding and supporting the true perpetrators of 9/11, allowing them to escape justice, and that this is allowing a false version of 9/11 to continue to be used to justify further terrorist activity which is still continuing today. Therefore, in Mr Rooke's opinion, to provide funds to the BBC through his TV licence fees would in effect be funding an organisation which is supporting terrorist activity, and under Section 15, Article 3 of the Terrorism Act, he would be committing a serious crime if he did this.

So, the question faces us: why does the BBC broadcast the presentation by Prof. Rosling? Is it just to bolster the global warming caused by humans myth or is there some other reason? I'll leave that up to you to work out.

However, perhaps we should take a look at the events of "nine-eleven" that being the American reference to the 9th November 2001. On that day, it was alleged that two large aircraft were flown into the two largest World Trade Centre buildings, the low grade aircraft fuel was then supposed to have ignited and the heat of that burning fuel weakened the steel in each building so that it collapsed under its own weight. The *9/11 Commission Report* states that the South Tower collapsed in ten seconds. That tower was 1362 feet tall (415 metres). The official story is so ridiculous that I'm told that it is being consider making disbelief of the story to be a punishable offence !! Now that is really spectacular, you are being told what to believe and punished if you don't accept an unbelievable tale. The official story is an insult to the American people in that they are clearly supposed to be too stupid to realise that the official statements cannot possibly be true.

So, let's ignore complicated calculations and advanced knowledge and just examine the facts from a common sense point of view. In her book "Where Did The Towers Go?", the university trained Civil Engineer Judy Wood, points out many impossibilities in the official story and she provides a great deal of facts and observations. We will not go into that level of detail here and just stick to a few damning simple details:

1. The official report says that the South Tower collapsed and fell to the ground in 10 seconds. That is physically impossible and didn't happen. First, if you dropped a cannon ball from a height of 1362 feet, it would take more than 10 seconds to reach the ground. Even if every support in the whole of the building were removed in an instant, it would take more than ten seconds for the building structure to reach the ground, and all support was not suddenly destroyed in an instant. The official story is shown clearly to be wrong. If the building had actually collapsed, then that would have taken more than 30 seconds.

2. The building is estimated to weigh about 500,000 tons. If that building collapsed, there would be such an impact with the ground that seismometers which watch for earthquakes around the world all day every day, would record that impact. The records show clearly that there was no such impact.

3. The area is below water level and the river water is kept out by a coffer dam. If a building weighing 500,000 tons collapsed on or near a coffer dam it would destroy the dam and the area would be flooded. That did not happen.

4. If a very large building collapses, there would be a major layer of debris – walls, floors, desks, chairs, computers, filing cabinets, etc., etc. There was no such pile of rubble as photographs show clearly.

5. Video graphics experts say that the video of aircraft flying into the building is wholly unconvincing and clearly a work of fiction.

6. An aircraft expert stated that it is physically impossible for the aircraft to have flown at the indicated speed at such a low altitude. It is stated that the aircraft would have to have about six times its actual power in order to have reached the stated speed at that level.

7. Hurricane Erin was heading directly for New York and was very close, and yet the weather service on TV did not mention it. Now why would that have been and who would have the authority to block that reporting? And, why would they do that?

We can see very clearly that the official story is definitely wrong and that the people carrying out the attack are able to tell the mainstream news services what to say, and prepare reports on the event before it happened, and give the script to Jane Standley of the British Broadcasting Corporation to read to the public in the full knowledge that the report was fake. These people were also able to suppress the broadcasting of Hurricane Erin details, presumably to raise the awareness of the attack on the Twin Towers. How unlikely is it that those people were a few Muslims? How likely is it that those people were Americans?

Before getting side-tracked by the fine details of the attack, let us draw some conclusions from the broad stroke information which is clear to everyone. Firstly, the official report is so clearly wrong that it implies that the people producing the report (not necessarily those compiling the report but those people telling them to compile the report) are actually involved in the attack, or at best, their bosses are. Secondly, a main objective would appear to be to unjustifiably slander Muslims in general and make Americans consider all Muslims to be “enemies” – a ridiculous attack to foster a ridiculous notion.

That of course, does not make any mention of persuading Americans to give up some of their rights and freedoms under the silly notion of “fighting terrorism” when in fact it is the people looking for those restrictions who are the terrorists. Nor does it make mention of it being an excuse to give tax money to whoever they want under the guise of “fighting terrorism”. Nor does it make mention of the pre-planned streams of refugees entering countries with the intention of diluting existing national cultures in preparation for one homogeneous world government.

Anyway, what did actually occur during the nine-eleven attack? There was little or no building material crashing to the ground because the building materials were converted to small particles which blew away on the wind, leaving only two or three inches (50 mm to 75 mm) depth of dust in the immediate area. So, what weapon could do that? Clearly, not a conventional weapon. Definitely not burning aircraft fuel. It has to be a “black project” development, probably a longitudinal beam weapon.

It should be noted that the buildings were demolished from the top down. With a disintegration weapon, you would expect the first material to be demolished will be that nearest to the weapon. While it would not be impossible for the effect to be the result of two or more roughly horizontal beams intersecting and the operators just choosing to start at the top, it seems likely to me that it was just one weapon located above the building. A stealth plane or satellite positioned high above the building could well be the weapon platform. Now, who would have access to such a platform? One thing which has not been mentioned is the distinct possibility that this was a weapons test as much as anything else.

Should Americans hate Muslims because of this attack? Not a chance !! Get real !!

2017 Update

The financial situation at the present time is difficult to assess, but some things are obvious if you have the facts to hand. There is about to be a major financial upheaval due to the way that money has been dealt with, the actions of bankers, and the mining situation.

Money and banking started with paper notes being issued by banks when a person deposited valuables with them. The valuables were primarily gold, silver, precious stones and the like. That system survived for quite some time but was then replaced by just paper notes without anything of value to give the paper notes any redeemable value. The result of that was that if you went into a bank and handed in a note marked with 100 of your local currency units, then all you could get in return would be another paper note marked with 100 units, or several other notes with numbers which add up to 100 of your local currency units. In other words, existing paper money notes are as valuable as Monopoly play money and have no intrinsic actual value because they are not backed up with anything of value. That kind of money is called “fiat” money and many scams have been based on it. The most recent is a pyramid scam which has to fail because it relies on the introduction of greater and greater numbers of suckers to keep the scam going. That type of scam has to fail as it is impossible to always keep introducing new people to the pyramid, and when it collapses, most people lose everything. So, if you have savings in a financial institution, then that means **You**.

There is an alternative. You can buy gold and/or silver. However, there is another scam being run on that as the sellers of precious metals point out that your precious metals could be stolen from you (by somebody other than them) and so, they suggest that they should keep your metals safely for you and just issue you with a paper certificate to say that you have those amounts of metals stored with them. If you are stupid enough to do that, then they issue up to 1000 more certificates on **your** metal and sell those pieces of paper to other people. When the bank closes down and disappears, then lucky you are left with pieces of paper – wow, almost as good as the worthless fiat currency pieces of paper !! So, instead of doing that, you get the actual metal sent to you and you keep it safely.

There are several options. You could have gold, silver, minted coins, or perhaps, jewellery. The smaller the item, the higher the price per weight. At the present time (March 2017) a scam is being run on the prices of gold and silver, with the price of silver being set far, far lower than it should be. The reason for this is interesting.

Gold is never really used up as it is just melted down and changed from one shape to another. Silver is a very different matter as it a great conductor of electricity and a great conductor of heat, it is used in the construction of solar panels (and China has doubled its solar panel manufacturing every year for many years now), batteries, Light Emitting Diodes, nuclear reactors, semi-conductors, computers, touch screens, water purification, and so many other uses that it has been described as the “indispensable metal”. Unfortunately, much of it is just thrown away when the item using it has reached the end of its life and so vast numbers of very tiny amounts of silver are lost continuously.

There is a problem. The amount of silver which can be mined economically is limited and silver mining as we know it today certainly will not be possible in twenty years. In reality, the break point could be reached in just two years and a period of eight years is an extremely optimistic assessment. The present very low price of silver is to discourage you and me from buying it while allowing the banks to buy vast amounts of it while it is still available. The banks then issue paper bonds against their stocks of silver, possibly as much as 1000 times as many bonds as the actual metal held, meaning that at least 999 out of 1000 people will be disappointed if they want to see the metal which they have paid for.

The crunch for silver will definitely come fairly soon and when it does, the initial price rise will tempt private holders to sell, but the reality is that the price is likely to rise by a factor of 70 times. That is, if you spent £100 to buy silver and received the actual metal in your hand, then you can expect that same piece of silver to be worth £7000 in today’s buying power, no matter what happens to any or all fiat paper currency.

You do need to avoid thieves, in particular, your ‘government’ which is likely to want to steal your metal when the price rises as it is bound to do. Governments have done this in the past, but they tended to concentrate on gold. Due to the mining limitations, they are likely to target silver in the future, so it might be sensible to store your silver in a secure location which is most definitely not a bank.

People becoming aware of how worthless fiat currency actually is, is leading steadily to the introduction of currency which is backed by valuable metals. Brazil, Russia, India, China and South Africa are already geared up for this changeover. These are likely to be interesting times.

There is an alternative which can be used in addition to buying silver, and that is Bitcoin. Bitcoin is a universal currency which does not require banks, does not require physical money tokens such as notes or coins and which operates worldwide. Fiat currency can be used to purchase bitcoins, or more accurately, small parts of a bitcoin. The purchase is then held in a mathematical "wallet" and can be used to buy goods or services. If you are not familiar with Bitcoin, then you should research it on the internet.

Chapter 16: Questions and Answers

This is a fast-moving field of research and development, and one where a single person working alone, can outperform research establishments with unlimited budgets and many staff members. If you believe that the answers given below are inadequate or incorrect, then please tell me as this is definitely a learning process for all of us.

Topic: What To Build

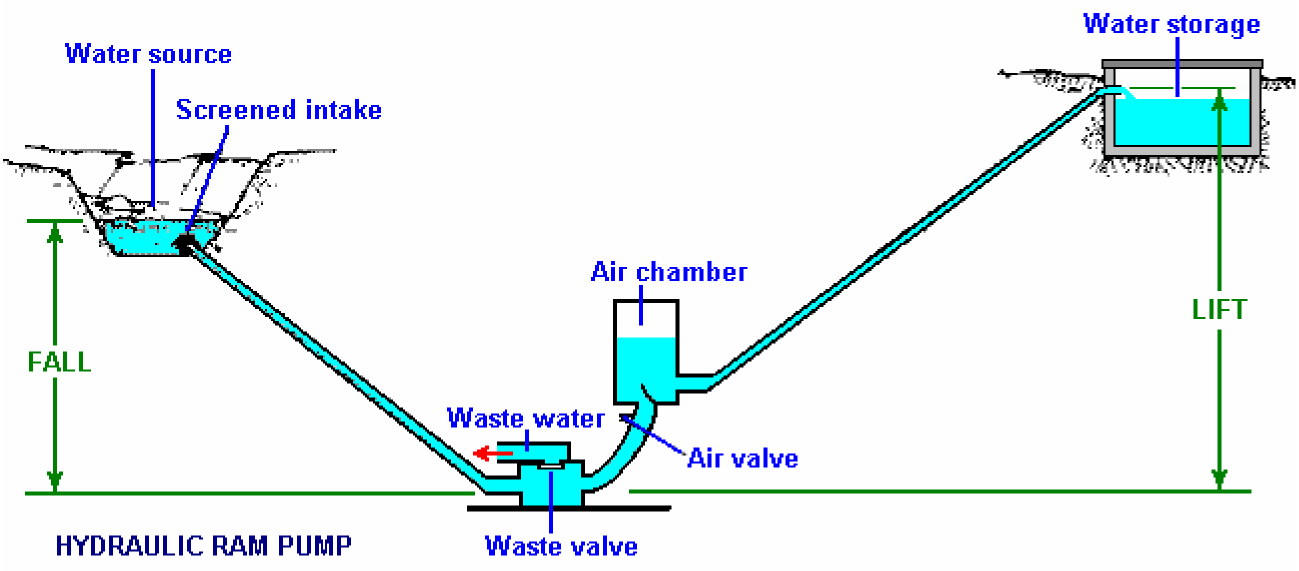
The QEG. Late in 2014, a document entitled The "Quantum Energy Generator" or "QEG" was published and I get frequent e-mails asking if it is genuine. I received the document within twenty-four hours of it being released, but I have no intention of publishing it. Please understand that I could be completely wrong and the QEG might be a great design, and I would be delighted if that were the case. What follows is my personal opinion and nothing more, so please don't take my reservations as proven or 'set in stone' never to be altered, but I have serious doubts about the QEG. It is presented as a design for everybody which can be built by anybody, but the repeated insistence that the device must be assembled by a professional "Electromechanical Engineer" combined with the insistence that extreme constructional accuracy is essential and so the components should be bought from their designated suppliers, seems to contradict the whole concept. Then, they strongly recommend donations to WITTS, which in my personal opinion is a bunch of scam artists. The only e-mails which I have received which contained swear words, were from people describing their experiences with WITTS. These are people who have paid WITTS large amounts of money and have received in return, nothing which they considered to be of any value. It has been suggested to me that WITTS puts forward expensive building plans for a device which they know will never work. Then, when the builder fails to get the device working, WITTS offers a very, very expensive telephone support service to help the builder "locate and correct his mistakes in building the device". That telephone support continues until the builder decides that the cost is not worth it, and abandons his project. I am not saying that that is the case, but it is a strongly held view with people who have dealt directly with WITTS. I have never dealt with WITTS as I do not believe in paying for information. So when the QEG document recommends donations to WITTS, that does not exactly raise its credibility in my opinion.

I am assured by a Tesla expert that the supposed link with Nikola Tesla is completely spurious as it is not relevant. In addition to that, the idea of altering a linear magnetic track to a circular motion never works in practice. However, the biggest single point is the wire specification which strikes me as being highly suspicious to say the least. The design specifies AWG #10 wire which has a current rating of 15 amps when wound into a coil. This design has two equal windings. I don't think that the windings are in parallel but let's say that they are, making the maximum sustained current for that wire to be 30 amps. Ignoring the extra 10% needed for self-powering, the claimed output of 10 kilowatts is a current of 47 amps at 220V or 94 amps at 110V, either of which would fry the wiring to destruction in a minute or two if conventional electricity is flowing through the wire. If it is cold electricity, then only tiny wire would be needed and certainly not AWG #10. Overall, I just do not believe the QEG design and suspect it to be a crude money-making scam, quite possibly intended to damage the free-energy movement as a whole. If you want to build a QEG, then by all means do that. I do not intend to build one.

General Questions:
However, on a more realistic level, I am regularly asked to recommend a device for someone to build. This is an impossible task as the person asking never says in which part of the world he lives, how much money could be used in the project, what tools are to hand, what workshop space (if any) is available, what local supplies of materials are like, whether the home is in a city or an isolated remote place, local assets like a shoreline, a fast-flowing stream or lots of sunshine all year round, continuous strong wind, how much ground space is available, what his skills are, etc. etc.

What should be realised is that a small group of friends can achieve a great deal. If one person likes working with engines and another can fix television sets and a third can weld, or … whatever. By working together, they can achieve a great deal and benefit both themselves and their friends, not to mention having a good deal of fun in the process and ending up with a great sense of achievement.

We should not dismiss the various forms of renewable energy such as wave power, RAM pump, solar panels, wind power, biomass and the like. Granted, they do not always provide power all of the time, but if they provide most of the power you need for most of the time you need it, then that can be a considerable saving on your present power costs, so you should consider the devices covered in chapter 14. One possibility is to use a RAM pump with a fast-flowing stream, to pump water up into a water tower over night, and use the tank of water to power a turbine driving an electrical generator when needed.



Water storage
Water source
Screened intake
Air chamber
LIFT
FALL
Waste water
Air valve
HYDRAULIC RAM PUMP
Waste valve

If you have the space and the sunshine, then a parabolic mirror can focus the sunshine, produce steam and drive a generator, a mechanical drive, a pump, or whatever else is needed.

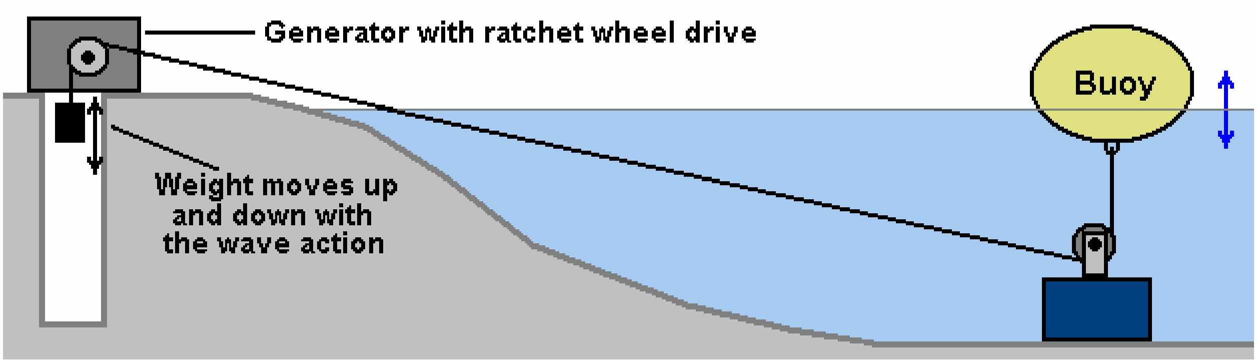
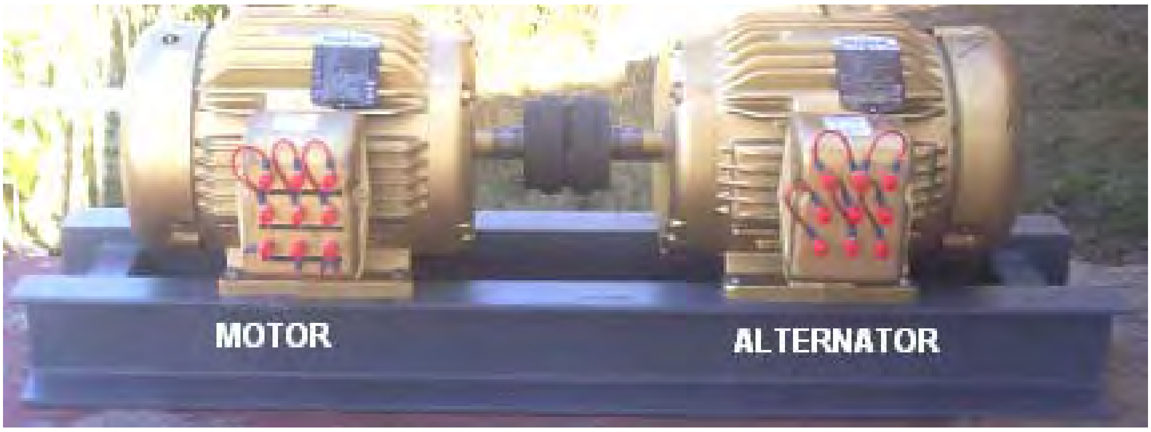
Above: Steven Vanek with his machine which uses solar thermal energy to make ice.

If you are lucky enough to have access to a small section of coastline, then using either wave power or tidal power gives a major amount of power each year with even a simple low-tech construction like this:



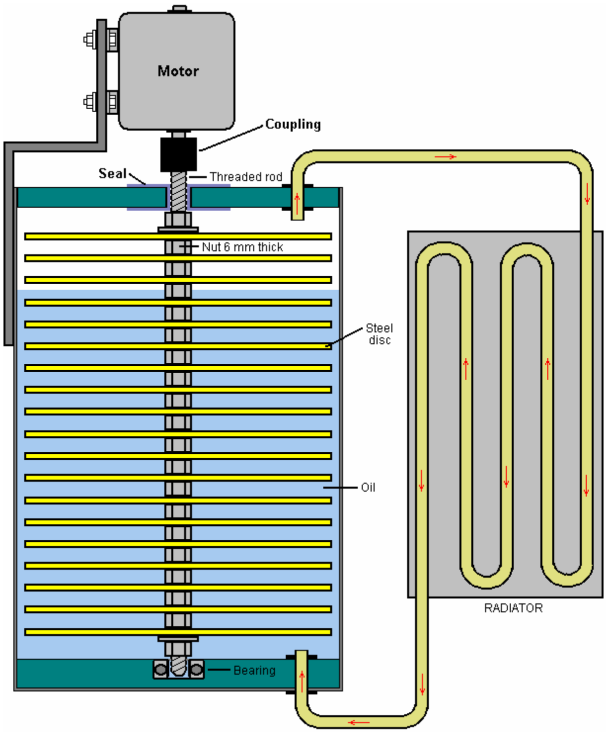
Generator with ratchet wheel drive
Buoy
Weight moves up and down with the wave action

It is not necessary to "go for broke" and aim at a device which will completely do away with your power needs for evermore. Initially, it can be a major step forward to produce a device which reduces your energy bill by a good deal and later on, progress to an additional system which makes you fully independent of others. For example, it is perfectly possible to drive a RotoVerter (chapter 2) with a solar panel:



The output is much more powerful than the input from the solar panel and can be used to run power tools, charge batteries or perform other useful tasks at effectively no cost at all.

The Frenette heater (chapter 14) does give significant heat output for the modest power input needed to spin the central shaft. It is a simple construction well within the capabilities of most people, and it could be driven by a solar panel if you live in an area where it is cold and sunny. As the array of discs spin, the vegetable oil inside the cylinder gets heated and pushed upwards and outwards, flowing through the radiator tubing, heating the house:

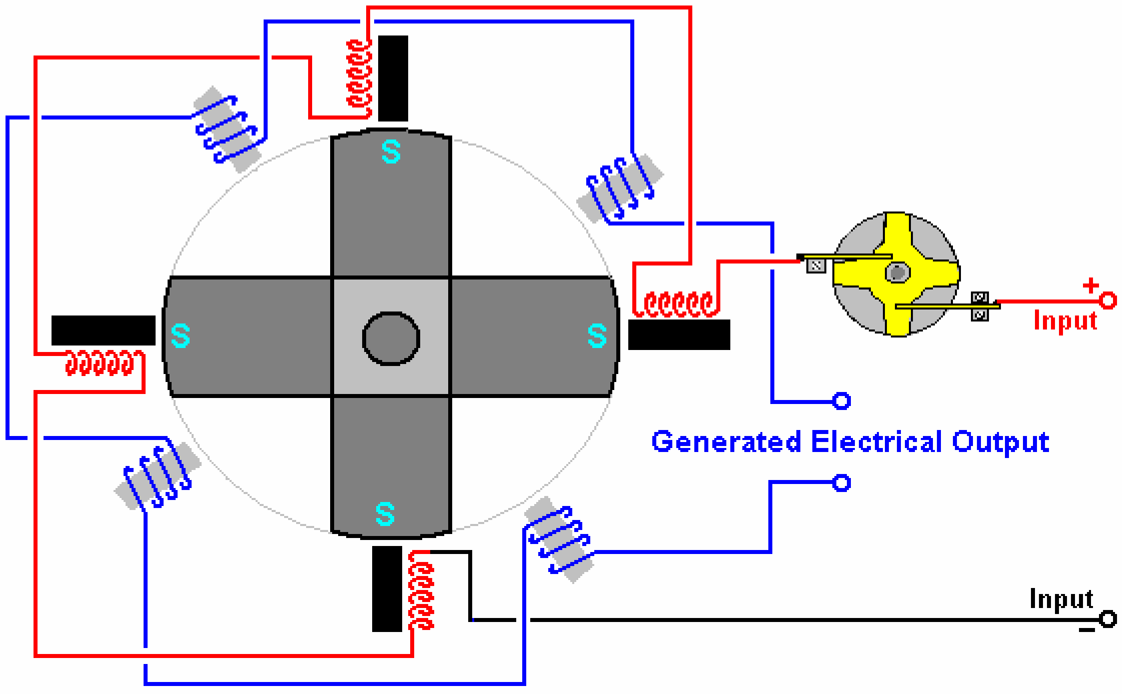


There are many high-performance alternatives which need special skills or equipment to build, but these can be found and constructed by those people who have above average skills and workshop facilities.

Devices which can provide power at any time, and at any location, include running a standard electrical generator with water as the only fuel (chapter 10). Strictly speaking, the generator runs on energy drawn from the environment and not on water.

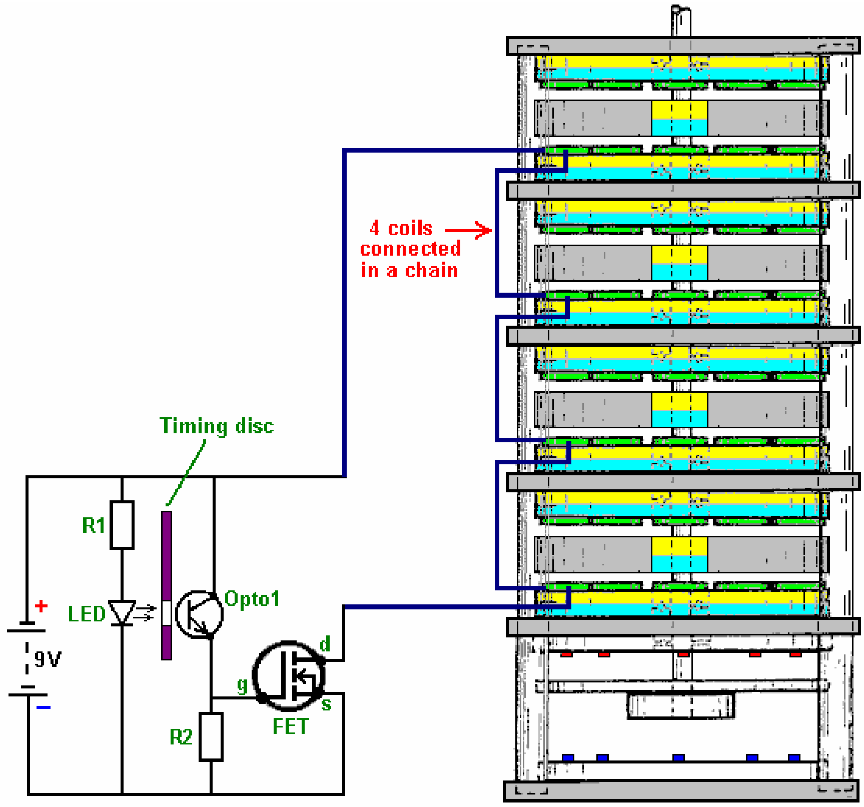
While it is perfectly possible to run this type of generator with water as what appears to be the only fuel, it must be realised that a generator of this type produces noise which will not be acceptable for neighbours if the user lives in a congested city environment. Admittedly, a suitable housing with many carpet-covered baffles would allow good air flow and cooling while reducing the noise to very low levels, but generally speaking, this is a solution for people who like working with internal combustion engines and who live some distance away from other people.

The Adams motor (chapter 2) when accurately built, can produce eight times as much output power as the power needed to make it operate. This is a good energy gain and the device is not difficult to build:



S
S
S
S
+
Input
Generated Electrical Output
Input
–

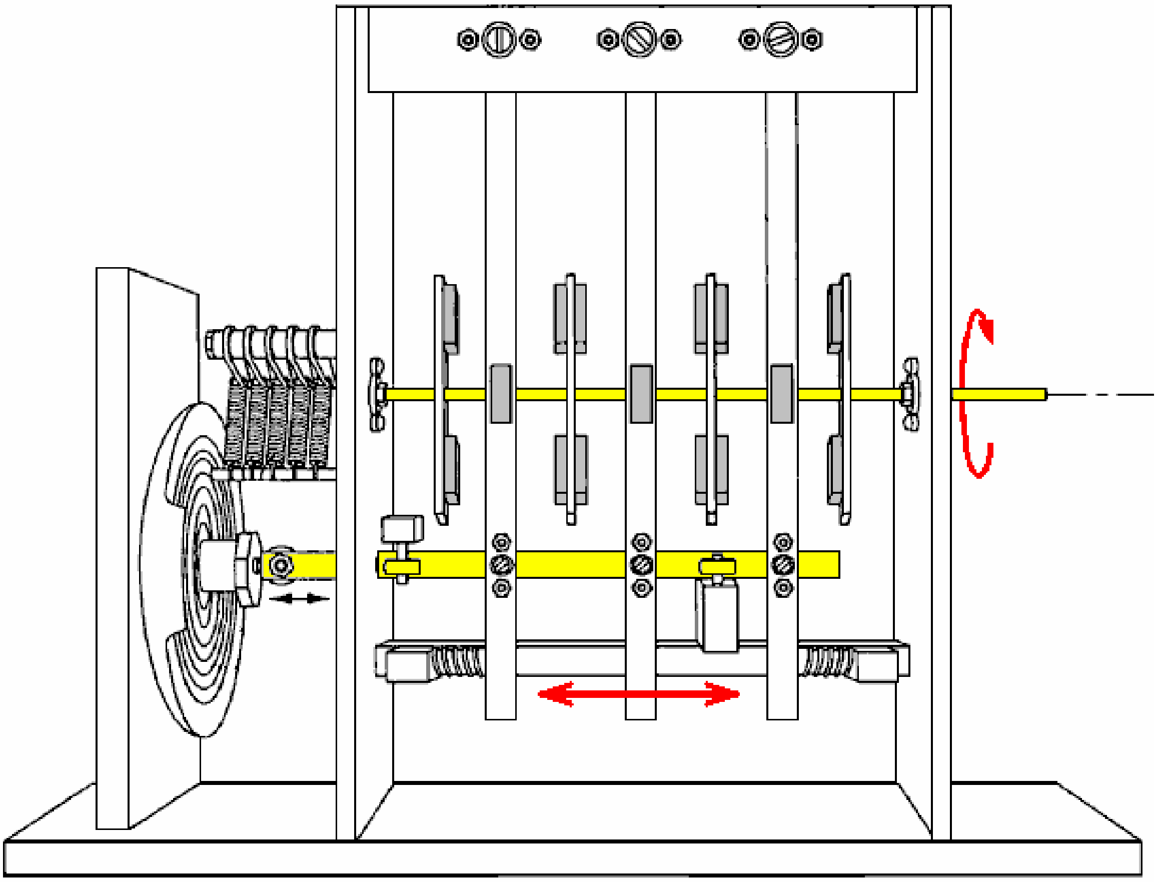
Another device which is not hard to build is the Charles Flynn magnet motor (chapter 1):



4 coils
connected
in a chain
Timing disc
R1
LED
Opto1
+
9V
–
d
g
s
FET
R2

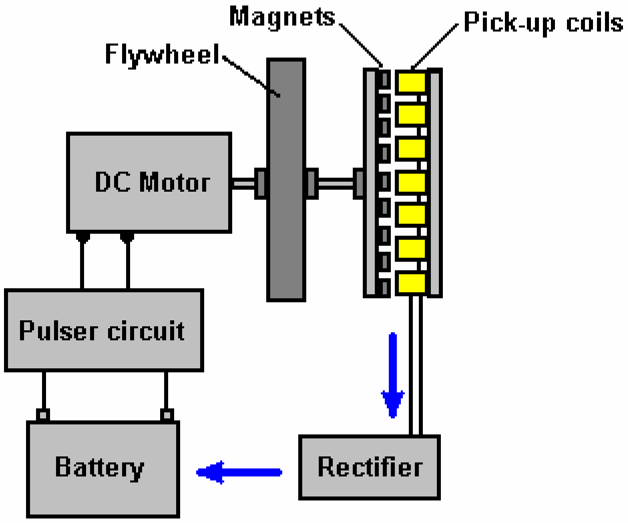
And if the electronics used to drive it is something which you have not come across before, then chapter 12 shows you how to understand and make these kinds of electronic circuits. A friend who is familiar with circuitry might help. A motor of this type can be made to produce any amount of power. Flynn's prototype ran at 20,000 rpm driven by just an ordinary 9-Volt dry cell battery. A big advantage with a motor like this is that you understand exactly how it works, and as you built it in the first place, if it ever breaks down, then you can fix it.

Another possible simple project is the Kundel magnet motor (chapter 1). Using just a simple rocking arm movement, powerful shaft rotation is produced. That rotation can be used as a mechanical drive, or to spin magnets past wire coils to produce electricity:



This motor operates by moving the magnets on the rocker arms, away from the rotor magnets when they would oppose the rotation and closer to the magnets on the next rotor which would promote the rotation. The rate at which the loudspeaker cone electromagnet is driven by an electronic circuit, controls the speed of the motor.

Another device which can supply extra power is John Bedini's pulsed flywheel (chapter 4). The objective is to apply a pulsed drive to a heavy flywheel. Each pulse acts as an impact, providing excess power to the flywheel. John had a small one of these running in his workshop for more than three years.



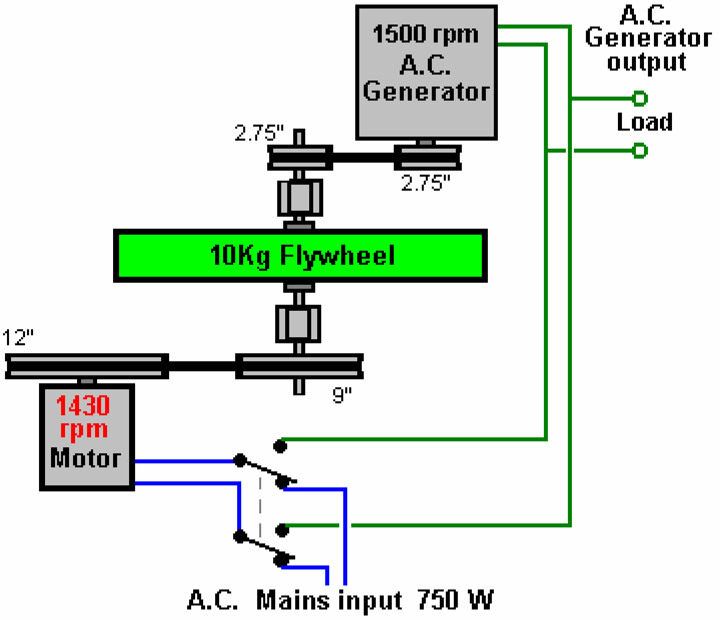
The DC motor is pulsed by a simple electronic circuit and the flywheel spins permanent magnets past a circle of coils of wire. The voltage generated in the coils is converted with four diodes to produce a pulsing DC voltage which can charge the battery and do additional work as well.

The output from a device of this nature depends on the size of the device. Jim Watson built one which was twelve feet high and he got 12 kilowatts of excess power from it. Obviously, I would not suggest that you build one as big as that, but perhaps one of say, three feet in diameter might have a very useful output. You have the option of wiring the coils in a chain in order to have a higher voltage output. If you do that, then have the same number of coils as permanent magnets so that they all pulse at the same moment. Alternatively, if you want to use magnets mounted with every second one having a different pole facing outwards and still have the coils in a chain, then have twice as many magnets as coils.

A similar wheel-pulsing method is used in the water-jet generator (chapter 4) which looks like a very simple thing to implement. Here, a jet of water provides a jerky drive to a wheel when the jet of water hits paddles attached to the rim of a wheel, geared through to an electrical generator.

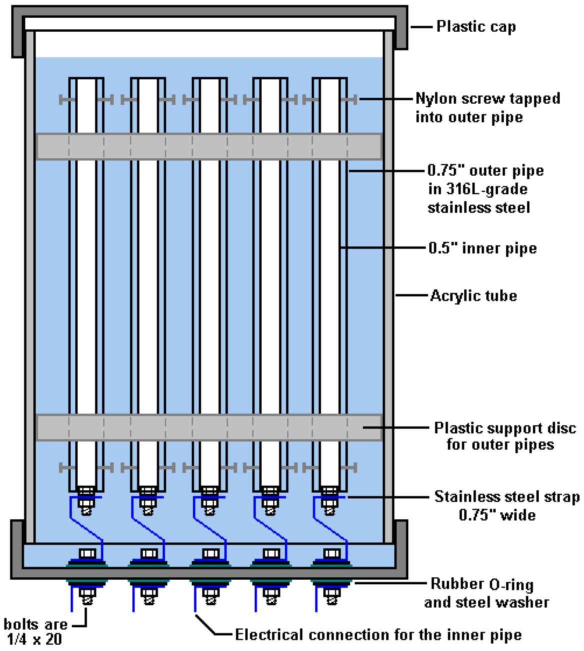
http://www.youtube.com/watch?gl=GB&hl=en-GB&v=zlinM1wAI5U has a video showing this arrangement in operation. If you decide to build it then please arrange for an external change-over switch located in a dry area outside the box for switching the pump over from the mains supply to the output from the generator as that is not something which should be done with a plug and socket in a wet area.

One of the most straightforward projects would be replicating Chas Campbell's flywheel system. Perhaps an arrangement like this:



Or if you prefer, an arrangement where there is more than one flywheel, again, keeping the flywheel shaft input drive pulley larger than the output pulley on that shaft.

Moving to a somewhat more difficult, but quite possible project. Dr Scott Cramton's version of Dave Lawton's electrolyser (chapter 10) is capable of generating a serious HHO gas output of 6 litres per minute of high quality gas for a very small power input.



Plastic cap
Nylon screw tapped into outer pipe
0.75" outer pipe in 316L-grade stainless steel
0.5" inner pipe
Acrylic tube
Plastic support disc for outer pipes
Stainless steel strap 0.75" wide
Rubber O-ring and steel washer
bolts are 1/4 x 20
Electrical connection for the inner pipe

This project needs patience as each of the tubes needs to be filed down so that they all resonate at the same frequency. Some minor electronics needs to be built and the pipes either conditioned or alternatively, insulated. The gas output can be used for heating, welding, cutting, cooking, boosting a vehicle or running a generator on water.

If you decide to start some project, then whatever project you pick, the most important thing is that it should be one which interests you and building it is fun. You will notice that the projects suggested here generally have moving parts which make it easy to see how the device is operating. The more difficult projects where there are no moving parts and meters need to be used can be left for a later time. If you decide to build something, then let me wish you good luck with your project.

A Matter of Opinion

This eBook is just a sharing of the information which I have come across during some years of investigating devices which are loosely described as being “free-energy” devices – a description which some people dislike because if costs money to construct or purchase a device which can produce useful work, even if the device appears to be self-powered. I am not an expert in the subject and so I have attempted to present the information in a direct and factual way.

However, I am regularly asked for my opinion on various devices and which one is best suited to some particular person, so, reluctantly, I will share some personal opinions on a selection of devices. Please understand that the following is just my opinion and could very well be completely wrong. Your level of interest in any particular device depends on your background and whether you are interested in a small device which proves that free-energy exists and can be harnessed, even though the output level is very small. Or if your objective is to obtain a device which can reduce your expenses. Or if you just want to investigate the subject for the sake of general interest. So, we have a wide range of different devices and a range of possible interests, so an attempt has been made to divide the devices into categories based on ease of construction and the output power levels produced by each device.

Please bear in mind that there has been a very high level of opposition to any of this type of information becoming well-known and so, information on each device tends to be limited, and while half a dozen devices may well be offered for sale in the future, at the present time few are commercially available, leaving you to build your own or get a friend to join with you in the construction, which is actually a very good idea as small groups of people can have a very wide range of skills.

Devices Which are the Easiest to Build

The Magnetic Frame of Lawrence Tseung (chapter 3)
The Transformers of Thane Heins (chapter 3)
Stephan Leben's adaptation of the Flynn Magnetic Frame (chapter 3)

These three devices have no moving parts and their performance has to be determined by measurements of the input power and the output power. They all operate by passing a fluctuating magnetic field through a frame, which is typically made from thin strips of laminated steel. These devices are limited in their power levels by the amount of magnetic flux which can be carried by their magnetic frames, and to a much lesser extent, by the maximum current which can be carried by the coil windings placed on those frames. Once the core reaches magnetic saturation, applying a stronger magnetic field to it has no effect at all and just wastes the additional power. So, in order to get any form of powerful output, the magnetic frame or core needs to have a high magnetic capacity, which typically means that the frame has to be big, which in turn, means it will probably be heavy and it may be expensive. Using specialised materials for the core could make a major difference, but most constructors will not have access to any of these nanocrystalline materials.

When properly constructed and operated, these devices can certainly show you that COP>1 is definitely possible. However, as the results are based on measurements, it is generally difficult to convince anyone else as many people will presume that you are operating a hoax as they have always been taught that any such operation is "impossible" as there is no such thing as "a free lunch". If you do want to comment on the input and output power levels, then be sure to measure the DC voltage and the DC current on both the input and the output as it will be argued that any form of waveform will give measurement errors.

The most convincing thing is if the device supplies it's own input power as well as supplying some additional item, even a single LED. Where the COP is greater than 1, this should be possible, but to keep the device operating steadily, I suggest that you use a voltage-stabilised circuit to supply the input power as that prevents a runaway situation where increased output power produces increased input power and a positive feedback is created which could lead to the almost instant destruction of circuit components which have been driven well past their rated values.

Clemente Figuera's Split Transformer (chapter 3)
The Figuera split transformer is exceptional in that it is completely free of the usual crippling Lenz-Law effects and it has the capability of outputs of several kilowatts. The details have been lost for more than a century and only recently been made available, so considerable experimentation is needed but the possible results are spectacular. If electronics does not appeal to you, then using mechanical switching like Clemente did, is a perfectly feasible method of construction. If you want to supply the input power from part of the output, then I would recommend using a stabilised power supply to ensure that only your chosen voltage is supplied as input power.

Carlos Benitez's Generator (chapter 5)
This spectacular design is capable of kilowatts of continuous excess power through the use of just two batteries. The design documentation explains how to calculate the size of the components and the mechanical switching is only used very occasionally and so can be replaced with simple solid-state switching to avoid mechanical construction.

Lawrence Tseung's "FLEET" Toroid (chapter 5)
This is a very easy device to construct and use, but it's output power is very small. Demonstration kits are due to be offered for sale quite soon. Developments are in hand and I have been told of a version which can run at six kilowatts. The presently known versions appeal enormously to many people who are intrigued that an almost totally exhausted single dry cell battery with far less than one volt, can charge a 6-volt battery or light LEDs for long periods. While this is definitely a 'fun' device, it is unlikely to convince anyone that 'free-energy' exists. A one-kilowatt version would be a very different matter. I have confirmed COP>1 operation by using one 12V battery to charge another, swapping the batteries over and repeating the process. The result was that both batteries ended up with considerably more genuinely useable power.

The Aerial Plate System (chapter 7)
This is also very easy to construct and being a modular system it has the advantage that it can easily be expanded to give substantial power outputs. This device is based on a Nikola Tesla invention and it has nothing to do with radio transmissions as it picks up ambient energy from the environment. While it can be used to charge batteries, it might also be used for direct power supply if suitable control circuitry is constructed for it. It needs a very high aerial and an extremely good earth in order to perform properly.

John Bedini's Simple School Girl Battery-pulser (chapter 6)
Alexkor's Solid-state battery-pulsers (chapter 6)
These devices can be very effective in what they do but they are not likely to convince anyone of COP>1 operation. Ron Pugh of Canada has achieved COP=13 with his implementation of the Bedini device running on 24-volts. It is difficult to demonstrate the actual performance as batteries are capable of getting a false "surface charge" which shows a high voltage but does not indicate a genuinely high level of recharging for that battery as the voltage will drop rapidly when driving a load. The only reliable way to assess the state of charge of a battery is to make it drive a load and observe how long it can sustain that load. The most recent, very-simple, solid-state Alexkor circuit has a COP=12 performance.

The Bedini pulse-charger has an impressive spinning wheel or rotor, but it's usefulness is severely limited as it can only charge batteries which are not being used to power a load. That means that it's charged batteries are only occasionally available, or two sets of batteries are needed, one for use while the other set is being charged. Ordinary batteries are not all that useful as their life is severely shortened if they are discharged in less than a 20-hour period.

Joseph Newman's Motor (chapter 11)
This is a particularly easy device to build and one which had an experienced technician considerably bothered by it's performance (as shown in Joseph Newman's book which can be downloaded from http://www.free-energy-info.tuks.nl/) as he could not explain how it could possibly perform as it does. However, the amount of power from any reasonably-sized replication will be low.

Internal Combustion Engine Boosters (chapter 10)
Simple boosters such as the "Smack's Booster" can be built quite easily and they can improve the burn quality of the standard fuel used in an internal combustion engine very considerably, reducing the unwanted emissions and raising the mpg figures by a typical amount of 20% to 40%. While building and using a booster, the actual installing of one in a vehicle does require some basic vehicle knowledge and a few basic tools.

Dietmar Hohl's Magnet Motor (chapter 1)
This motor has been replicated and proven to work. Given a little care when constructing it and angling the stator magnets as shown gives a considerable improvement in the power available. However, as shown with just one V-set of magnets and one cylinder of stator magnets, the power is not that great although it demonstrates conclusively that permanent magnets can be used to provide power and demonstrate "perpetual motion" which is so much feared by "scientists" because it shows that their pet theories are, at best, incomplete and at worst, completely wrong. To get some power from this motor design, you need to use a larger diameter drum with two, three, four or five sets of V-magnets around it's circumference, and possibly more than one set of magnets along the length of the drum. The number of magnets involved in even the minimum arrangement is quite large.

Ben Teal's Motor (chapter 1)
This motor design is very, very simple and the first version was built using wood and it proved to be very effective, having a two-inch (50 mm) diameter drive shaft. Ben found that he was unable to slow or stop the motor by grasping the drive shaft as the motor was just too powerful. This motor has not been shown to be COP>1 but I wouldn't be surprised if is.

Don Kelly's Magnetic Motor (chapter 1)
I have never heard of anybody building this design. It has the potential for serious COP>1 operation as the driving power comes from the magnets and only a small amount of power is needed for the motors to move the stator magnets. I see synchronising the motors as being a potential problem and so would suggest that using only one motor to drive all of the stators as being a sensible option. The motor speed during start-up can be controlled manually with a DC Motor Speed Controller and then the setting just left when it is running at full speed. It could be used to drive sets of magnets between coils to generate electricity and that output boosted substantially further with the coil-shorting method described in chapter 2.

Stephen Kundel's Magnetic Motor (chapter 1)
This is a very simple and direct method of getting permanent magnets to provide continuous drive with just a very low electrical input used to change the location of the stator magnets in much the same way as in Don Kelly's motor design. The movement is very simple as it is just a rocking movement, driven by the mechanism used in a loudspeaker. As there can be as many sets of rotor and stator magnets on any drive shaft, the power of this design can be substantial.

Raoul Hatem (chapter 2)
This arrangement of magnets and generators is expensive as each generator uses thirty-six powerful magnets to give good magnetic coupling between the drive motor and every generator. Some people believe that this design cannot possibly be COP>1 as the motor drives each of the generators (although most are driven indirectly). I don't know if that is correct or not, but there is the possibility that as the motor creates a rotating magnetic field

whether or not there are any generators there at all, it may be that the fact that a nearby generator happens to use that rotating magnetic field to rotate its armature, has little effect on the drive motor. Certainly, Raoul didn't keep buying and adding extra generators if he was not getting any benefit from them. This arrangement has the potential of serious power gains, but it would be fairly expensive to investigate if that is indeed the case.

John Bedini's pulsed flywheel (chapter 4)
Lawrence Tseung's pulsed flywheel (chapter 4)
These are definite winners. Jim Watson built a monster size version of John's which was self-powered and had 12 kilowatts of excess power. Lawrence Tseung's prototype is only low power but it demonstrates COP>1 very clearly indeed on only one set of rotor magnets. The design performance should be dramatically increased by using several sets of rotor magnets as that would raise the power levels considerably. This is a very easy home-build project requiring very little in the way of constructional skills or specialised tools.

Lawrence Tseung's Impact Gravity Wheel (chapter 4)
This is a device which has been replicated and it too demonstrates the "impossible" perpetual motion so feared by our revered "scientists". It requires minimal skills to replicate and the components are all low-cost. Definitely and interesting project to build and investigate and one which has the potential of power generation without the need for any form of input power or fuel.

The Nudged-weights Design of Mikhail Dmitriev (chapter 4)
This is a design which I have only encountered very recently and it has major potential. It does with weights, what designs like Kundel and Kelly do with magnets. Energy is extracted from the gravitational effect (if you will pardon the expression) as weights are pushed downwards. The lever arm for those weights is longer than the lever arm when they are being lifted upwards again, and that gives a continuous turning force. The increased lever arm for the falling weights is caused by a small electric motor giving them a nudge away from the rotor axle. Before the weight has time to swing back into it's vertical position it's rotor pivot has reached the bottom of it's travel. In some of his designs, Mikhail just allows the weight to swing freely and in other designs he uses an angled ramp to control and limit the positioning. The brief presentation in chapter 4 shows tiny weights, but even for a first-time home-build replication, there is no reason why the weights should not be substantial. They can be suspended and given a ball or roller bearing suspension and the motor can have broader strips which press directly on the rectangular body of the weight. Mikhail is thinking of marketing ready-built units providing 6 kilowatts or more of electrical power, and plans and kits as well. The rotor turns slowly and powerfully and so need to be geared up to increase the speed for electrical generation.

Chas Campbell's Pulsed Flywheel (chapter 4)
This is a good design for people who do not want to get involved in electronics as it uses standard mechanical components and an off-the-shelf motor and generator. I don't know of anyone who has replicated this design, but since nobody has any particular reason to tell me about what they have done, that does not mean anything much. The potential for excess output power is high although Chas has not made any output power measurements.

James Hardy's Water-jet Generator (chapter 2)
This device is both patented and shown on video on the web. It is very, very simple in concept and should be easy to build. Unlike the video demonstration, a proper working model is wholly enclosed and fairly quiet in operation. It is self-powered and has significant excess electrical power. Construction is very straightforward and uses readily available off-the-shelf components.

The Robert Adams Motor/Generator (chapter 2)
If built without paying any attention to the essential details, this design will operate but always be COP<1 in spite of the design having an extremely high potential. If care is taken with the construction and high voltage used and the timing adjusted to it's optimum settings, then an input of just 27 watts has been shown to produce 32 kilowatts of power, capable of running a household or office. Adjustments for optimum performance will take time and patience and this design is more suited to people who have some understanding of electronics.

Pyramids (chapter 9)
The usefulness of a pyramid depends to a considerable degree on how sunny the local environment is. The bulk of the energy which they concentrate flows from the sun, so sunny areas have a much higher pyramid effect than dull areas where direct sunlight rarely reaches the ground. A pyramid is not particularly difficult to construct if you have the dimensions, but size is very important with increased size having a disproportionate effect. In this area, bigger is definitely better. Covering the pyramid with gold-plated iron is the optimum, but many other much cheaper materials can be used very effectively. Pyramids are probably better used to enhance growth and for health improvement purposes rather than for generating electrical power.

The Tesla Coil and Grounded Plate (chapter 5)
This method for extracting substantial power was disclosed by Nikola Tesla and has been demonstrated in broad outline on video by Don Smith, although he did not demonstrate equipment being powered by the electrical

energy generated. A standard Tesla Coil (available commercially) directed on to a metal plate or two-plate capacitor which is connected to an effective earth wire, can supply serious amounts of electrical power. Nobody seems to be interested in using this method to generate excess energy and it is not at all obvious why that should be.

Art Porter's Magnet Motor (chapter 2)
This is a variation of the Charles Flynn motor where an electromagnet coil is used to modify the magnetic field of a permanent magnet. Art states that he gets a 2.9 times improvement in the field strength doing this and he uses it to operate a reciprocating motor. Instead of having mechanical movement, it seems as if it would be more effective to use that magnetic field alteration to generate electricity in a stationary coil as that seems likely to give a COP>1 performance and the currents used could easily be high, giving substantial excess output power. It should be perfectly possible to have a whole bank of these magnet/coil combinations in a single device.

Linked AC motors (chapter 2)
Although the output is very small and despite the fact that it is by no means certain that these designs are not fake, the construction is so simple and the component cost so low, it might well be an interesting experiment to try out linking one 220V motor and one 240V motor to see if they actually do operate as shown in the videos when a 400V capacitor is placed across the linking wires.

Alexkor's Zero back-EMF transformers (chapter 3)
As these designs are easy to build - especially the toroidal ones - they could well be an interesting place to start. I would suggest using the output of a mains 6V transformer for the initial testing of these designs.

Lorrie Matchett's system (chapter 3)
This is a very simple design to make and test. However, please be very, very careful to ensure that all metal objects connected to the mains are fully insulated before you start testing.

The Kelichiro Asaoka Motionless Generators (chapter 3)
As far as power output is concerned, thiese could be major winners due to their simplicity and simple design combined with the fact that once built and tested, larger version can then be made using the experience gained by the small versions.

Devices which are of Medium Difficulty

Charles Flynn's Magnet Motor (chapter 1)
This design is powered by permanent magnets which are intermittently shielded by electromagnet windings. As the construction of those windings depends on the voltage being used to drive them, the spacing between the magnets and the strength of the actual magnets used in the construction, experimentation needs to be undertaken before the final construction and assembly is undertaken. An understanding of basic electronics is needed. The power and speed of the motor are exceptional. The input power needed for the prototype described by Charles is very low with just an ordinary 9-volt dry-cell battery being able to power the motor at 20,000 rpm. If the motor is used to drive a generator (whether home-built or commercial), there does not appear to be any reason why the input power should not be provided by a voltage-stabilised power supply driven by the output, making this a self-powered system which can power other electrical equipment or a mechanical load.

Victor Diduck's Permanent Magnet Motor (chapter 1)
This design gives exact dimensions and is one of the very powerful cylinder motor designs. It should be possible to replicate this design and produce a powerful motor able to spin a standard generator producing kilowatts of power.

Electrical Generator Running on Water (chapter 10)
As far as power output is concerned, this is a major winner as it is both self-powered and provides kilowatts of excess electrical power. As so much electrical power is generated, the design of the electrolyser used should not be critical. While the generator spark timing can be delayed so that just HHO and cold water mist can be used, the David Quirey method of bubbling the HHO through acetone, allows an unmodified generator to be used, making the project very much more simple. This project is particularly suited to people who like maintaining, adjusting and tuning vehicles.

The Pulsed Coil of 'UFOpolitics' (chapter 3)
This is a design which generates cold electricity which can safely light a bulb under water. With no moving parts, the only (minor) difficulty is constructing the electronics to drive the coil. Running off 36V, this is a very interesting design for people who want to experience the remarkable effects of cold electricity.

Bill Muller's Motor/Generator (chapter 2)

Ron Classen has replicated this design and reached COP=2.2 after very considerable expenditure of time and money. You need excellent mechanical skills to be successful with this design although the coil-shorting technique might well raise the electrical output very substantially.

The RotoVerter (chapter 2)
This design involves running a 3-phase motor from a single-phase power supply. The capacitor tuning needed to do this depends on the loading of the output unless Phil Wood's method of adding in a DC motor is used. This project mainly requires mechanical skills rather than out and out electronics. This arrangement is best suited to where an existing motor is used extensively and under those circumstances, the cost of running the original motor can be reduced substantially by the RotoVerter system and the system can be run on a solar panel used with an inverter.

Richard Willis' Motionless Generator (chapter 3)
Silverhealtheu's adaption of the Willis Generator (chapter 3)
Richard has shown his generator on the US version of The Dragon's Den television programme and he has offered his "Magnacoaster" generators for sale. I understand that the technical problems initially encountered have now been overcome and so units should be shipping at this time. The simplified 'silverhealtheu' version should not have any problems when run at reasonable power. These devices are a starting point for experimentation and they are best suited to people who have some knowledge of electronics.

Dan Davidson's Acoustic Generator (Appendix)
Pavel Imris' Optical Amplifier (chapter 3)
These devices appear quite straightforward, but I have never heard of anyone actually attempting to replicate either of them. That being the case, they would need to be categorised as being designs which need further investigation if they are to be home-built.

Dale Simpson's Hinged Plate and Gravity Wheel (chapter 4)
Murilo Luciano's Gravity Chain (chapter 4)
These three devices have to be categorised as being untested designs and some people are of the opinion that they can't work. Until such time as they are built and tested, they have to remain as design ideas. The construction is not particularly difficult being mainly mechanical in nature, but there is no guarantee of success and it seems unlikely that the components could be easily used again in some other project.

Dave Lawton's Hydroxy Cell (chapter 10)
Dr Scott Cramton's Hydroxy Cell (chapter 10)
Bob Boyce's Electrolyser (chapter 10)
These three designs have very impressive performances, far outperforming Michael Faraday's efficiency results (which "scientists" believe are the maximum possible). For example, Bob Boyce's electrolyser design run on DC, can have efficiency results over 200% those of Faraday. Run on pulsed DC, the same electrolyser can reach 1,200% Faraday's maximum. The Lawton and Cramton cells, operating differently, also have outputs which are far in excess of Faraday's results. As more power is available from recombining the gas mix produced through burning when diluted with air and/or non-combustible gasses, or through use in an internal combustion engine, these devices represent considerable possibilities. However, the amount of work involved is not trivial and the use of the gas mix produced calls for ingenuity, so these are devices which have a high potential but they are not an instant-fix for anything.

The Rosemary Ainslie Heater (chapter 5)
This is a most interesting design which has COP=17. However, at the present time, power levels are so low that while it may be an interesting project and the principle is more than interesting, the output of this device is too low to provide any form of useful heating.

Robert Patterson's Ram Wing (chapter 10)
This is a simple physical device capable of improving the air flow around a moving vehicle to such an extent that it produces better mpg figures for the vehicle. Constructing one and mounting it on a vehicle is not a difficult task and the gains can be significant.

Co-Axial Cable Electrets (chapter 9)
This is a system which nobody seems willing to try. It involves baking a reel of co-axial (TV aerial) cable in an oven and allowing it to cool down very slowly. It is capable of supplying 10 mA at 10,000 volts which is a continuous power of 100 watts (better than most solar panels). The output energy from this passive device is drawn in from the surrounding environment. The high voltage of the output appears to put people off this device.

The Colman / Seddon-Gillespie 70-year Battery (chapter 3)
This is a device which has major potential and yet one which nobody seems interested in attempting to replicate. It is a small, compact, simple device which can provide one kilowatt of excess power for an estimated seventy

years. Several of these in a single small housing could supply the electrical needs of a whole household. The materials used are not hazardous in any way and apart from some basic electronic circuitry and experimentation, there does not appear to be any problem with attempting to replicate it.

Robert Krupa's "Firestorm" Spark Plug (chapter 10)
This plug design is quite capable of giving improved fuel burn inside an internal combustion engine that the mpg performance can be increased very substantially and harmful emission drastically reduced. While Robert has a patent on his designs, he has not been able to find any manufacturer willing to make and sell Firestorm spark plugs. Prototypes have been made by getting a jeweller to modify a new set of standard spark plugs. This is expensive, but it is definitely something which is possible to do.

Jesse McQueen's Self-powered System (chapter 13)
On the surface, the patented proposal by Jesse appears to be impossible. However, as our understanding of how the various free-energy devices draw in environmental energy increases, some of the more impossible looking devices suddenly look as if they might actually be based on principles and methods which have been proven to work. Essentially, a battery powers a motor which spins a generator which keeps the battery charged and powers other devices. If both the motor and the generator are COP<1, then the system won't work. But, gearing is used between the motor and the generator, and Chas Campbell has shown that with a flywheel in that linkage, additional power **is** actually available. It may be that Jesse does not mention the fact that his gearing linkage is heavy. It is interesting to note that the gearing that he specifies, has the correct ratio that Jacob Byzehr specifies in his patent for an energy gain through such linkage. It seems likely that Jesse has not disclosed all of the details in his patent. While constructing a test bed for this system should be easy if you have the components to hand, I suggest that you consider it to be an experimental investigation of his claims and don't expect immediate, spectacular results.

Robert Tracy's Permanent Magnet Motor (chapter 1)
This style of motor with magnetic shields being physically moved between pairs of magnets is probably one of the more difficult magnet motors to get operational. The main problem is getting an effective magnetic shield material. The expensive "mu-metal" material is supposed to be effective if it is fairly thick, but I am by no means sure that this is the case in actual practice. Screening powerful magnets with a passive material is not an easy thing to do and there are very few materials which seem able to do it. It might be possible to use a thin neodymium magnet as the 'shield' if it were orientated so that it was in repulsion mode for both the stator and rotor magnets as they approach each other.   Because of the screening material problem, I could see the building of a Tracy prototype to be a lengthy experimental process in spite of the fact that the theory is perfectly sound.

The Power Generator of William Skinner (chapter 4)
This design is simple and as it was built and demonstrated in 1939 before electronic components were readily available, it could be built without any electronics knowledge at all. Power output can be very high.

Devices which require higher skill levels

Muammer Yildiz's Permanent Magnet Motor (chapter 1)
This motor has been demonstrated in a Dutch technical college and taken apart after the initial running was completed, showing that it's operation was wholly genuine. However, some of the magnets used are of a tapered type which are probably not readily available unless ordered as a specially constructed batch which is generally an expensive way to buy magnets. Magnetic fields and their interactions and distortions are not the easiest things to understand or observe in a practical situation, and that makes the construction of permanent magnet only motors a difficult job. Howard Johnson and Mike Brady managed to make successful prototypes but then found it almost impossible to make others to that same design. So, if you decide to replicate Muammer's motor, please understand that it is not likely to be an easy thing to do.

Michael Ognyanov's Self-Powered Power Pack (Appendix)
This is a low power device intended to operate the lights on road traffic cones without the need for a battery. There should be no particular problem in building it if it were not for the need to cast a semiconductor block from a mixture of materials such as silicon, germanium, neodymium, gallium, etc. It seems likely that the average home constructor of devices is not geared up for melting and casting such materials, and so that puts it into the 'higher skills' bracket.

Don Smith's High-frequency, High-voltage Devices (chapter 3)
These devices appeal to a high percentage of interested people and yet they seem to be some of the most difficult to replicate. Admittedly, Don does say that he has not revealed all of the details on any one of his designs, but independent people have confirmed that doubling the voltage quadruples the output power and that additional electrical outputs can be produced from the fluctuating magnetic field without requiring any additional input power. Considering the limited success encountered by several people who have tried to construct replications, these

devices have to be rated as some of the most difficult to get operational. Having said that, success has been achieved by putting two Tesla Coils back-to-back, connecting their secondary coils with a wire and taking the output from the larger diameter “L1” coil of the second Tesla Coil.

Jerzy Zbikowski’s Chain Drive (chapter 4)
This device looks impossible, and yet it is reported to have been laboratory tested at COP=1.47 which is quite remarkable. As it is a mechanical chain drive, it requires good mechanical skills to construct the chain links and the two sprocket wheels. The mechanical operation needs to be high-quality, so it is unlikely that beginners to mechanical construction would have immediate success.

The Magnetic Pendulum (chapter 4)
While I don’t know the name of the builder, this pendulum is reported to have been swinging continuously for more than two years now and while it does not appear to generate any useful power output, it is certainly an amusing project, especially should you want to show it to those people who say that ‘perpetual motion’ is impossible. It might well be possible to adapt it so that the magnetic push provided by dropping permanent magnets downwards near the end of the swing were provided instead by a coil which extracts power and then, when the current is cut off, generates the necessary push from the magnetic field generated by the back EMF. While the output power would be low, it would be very nice to demonstrate power generation with no input power being provided – just pure energy extraction from gravity and magnets (both of which are powered by the zero-point energy field).

The Tesla Switch (chapter 5)
This is one of the most difficult devices to get operational, in spite of the fact that it appeals to a large number of people. There are three possible modes of operation. If the diodes are turned the wrong way round so that they can feed current from each battery, then the operation will definitely be COP<1 but it will be a good deal better than operating without the switch circuit in place.

The second way has only been achieved by John Bedini as far as I am aware. This is where the circuitry is the same but the circuit components and connecting wires are adjusted very carefully to produce circuit resonance. When that happens, the circuit becomes self-powering although there is little or no extra power for other devices.

The third way was developed and tested over three years by staff of the Electrodyne Corporation in America. In this version, the diodes are reversed and they only feed sharp voltage spikes back to the batteries, through the diodes which supposedly don’t allow current to flow in that direction. This is a very different form of operation where the operating power flows into the circuit from the local environment. The batteries need to be ‘conditioned’ through long periods of being operated this way as the ‘cold electricity’ used in the circuit is the opposite of the ‘hot electricity’ which the batteries have been using up to now. This long conditioning period is generally enough to make the average builder give up and believe that the circuit just doesn’t work. Dave Lawton was faced with exactly the same type of problem when he attempted to replicate Stan Meyer’s “Water Fuel Cell”. It appeared ‘dead’ and produced nothing during a whole month of testing, and then it suddenly burst into life, producing large amounts of HHO gas mix for almost no electrical input. Without his exceptional patience, Dave would never have succeeded. I believe that the same applies to the Tesla Switch when wired correctly with the diodes blocking current flow from the batteries – it is likely to take long-term and patient testing before the system swings into life.

One experimenter who did not believe the diodes could possibly work that way round, tested the arrangement and discovered that in spite of the theory, in practice, the reverse-biased diodes actually pass very sharp voltage spikes to the batteries, so the effect may well be like a slick version of John Bedini's battery pulsing circuits.

Hermann Plauson’s High-Power Aerial Systems (chapter 7)
Hermann Plauson’s patent which is in the Appendix, is so detailed and authoritative that it gives every indication that he is highly experienced in the actual design, construction and installation of serious aerial installations. He casually refers to “small” installations as being those of 100 kilowatt or lower capacity, so we are not talking about milliwatts here, although I understand that Hermann extracted somewhat under one kilowatt per aerial and used many aerials in any one installation. The difficulty with these types of system is that the input is very high voltage ‘electrostatic’ electricity, usually though of as being useless for power generation. It is therefore, important to consider carefully the mechanisms which Hermann has in his patent for converting that power to ordinary electricity at normal voltage and current levels. We need to remember that Paul Baumann’s “Thestatika” devices operate off this type of input power and yet put out kilowatts of mains electricity, so we know that it is perfectly possible. We do not have step-by-step building instructions for these types of system, and so they have to be rated as requiring more than the lowest skill levels. Also, many people are not located where they can erect a tall aerial, but remember that the Thestatika uses a Wimshurst style electrostatic generator rather than an aerial, so experimenters can work with a generator input. A.D. Moore’s “Dirod” electrostatic generator seems like the most suitable home-build generator. It is described in detail in his book “Electrostatics – Exploring, Controlling and Using Static Electricity” Second Edition ISBN 1-885540-04-3 which is the only source for construction information on his generator.

Frank Prentice’s Ground Aerial System (chapter 5)
Frank’s design uses a one mile long wire supported just a few inches above the ground. He inputs a modulation signal of 500 watts and extracts 3 kilowatts of power. The information in his patent is not exactly overwhelming in it’s details, but the major obstacle is that very few people can install any such wire. It is not known if the wire could be run backwards and forwards over a small area, but if that were possible, then it would form a barrier against the normal use of that area. Frank didn’t have that problem as he worked on railway tracks. The limited amount of information adds to the skill level needed to be successful with his design.

Alfred Hubbard’s Electrical Generator (chapter 5)
This has a very high potential as it can put out substantial electrical power in spite of it’s simple construction. As it is based on just one section of the magnetisation graph where a small additional current produces a major rise in the magnetisation of the iron core, it will require careful adjustment and attention paid to the magnetic saturation levels of the materials used. It is very interesting that Joseph Cater’s analysis of the device has spacings which match the recently discovered optimum tube spacings for the Joe Cell. I am not aware of anyone who has managed to replicate Alfred’s device.

Joseph Cater’s Water-filled Generator (chapter 5)
This looks like a really good design but it has the problem that it needs a transducer or klaxon running at 600 kHz and there does not appear to be any such transducer readily available on the market. The highest frequency I have located was just 300 kHz which is clearly not suitable, so this design appears to be restricted to people who have skills which can design and construct a klaxon which can operate at 600 kHz.

Joseph Cater’s ‘Orgone’ Box (chapter 9)
The ‘Joe Cell’ (chapter 9)
The ‘Nitro’ Cell (chapter 13)
In theory, each of these is capable of running a car engine without the need for any form of combustible fuel. I am aware of people who have succeeded in doing this with the Joe Cell and the Nitro Cell, but they both live in much sunnier locations than I do. These devices are some of the most difficult to get operational and it could well take a week for the car to absorb the cell influence before it can run without fuel. It has to be said that the technology involved in the operation of these devices has not been fully documented at this time and so is not fully understood and so experimenting with them is effectively a research project.

Fuel-less Engines (chapter 8)
These engines are perfectly viable but few people have the knowledge, skills, tools, workspace, inclination and time to go building or modifying an engine. These are Engineering tasks and not generally suited to ’back-yard’ projects.

The Searle-Effect Generator (“SEG”) (chapter 11)
According to John Searle, constructing just one of the many magnets needed for his generator requires more than a day of work and a million pounds in finance. This is enough to put most people off even considering his design. However, John certainly didn’t spend anything like that amount of money when he built his first successful prototype, so we can probably ignore the quoted costs. Investigation would need to take place through the enthusiasts on John’s forum and web site, but unless something has changed recently, it will probably take considerable research and subsequent thought in order to come up with a viable design for the construction of a useful generator or a flying disc.

Michael Eskeli’s ‘No-Work’ Turbine (chapter 11)
Michael is clearly a gifted and very competent man who has many patents. In common with most gifted inventors, he does not excel in explaining and documenting his inventions and so a certain amount of background Mechanical Engineering knowledge would be of major help in understanding how to home-build one of his designs. The No-Work heating turbine in chapter 11 is a heater which only needs the friction of the bearings to be overcome by the motor spinning the turbine as the actual heating effect is ‘free’. This is, of course, spectacular. If you happen to be a gifted individual and replicate Michael’s turbine, then I would be most grateful if you would fill me in on suitable construction methods so that I could expand the description into a more detailed version which would encourage people to build one for themselves.

William Hyde’s 10 kW Electrostatic Generator (chapter 11)
This involves the construction of a rotary generator with metal bodywork and so metalworking skills are needed (or somebody else with those skills needs to help out or be paid to do the work). The completed electrostatic generator has been patented and it is claimed to have an output of ten kilowatts of ordinary electricity, which makes it of serious interest to anyone needing to power a household. It is reputed to be COP=10 which means that the input power will be substantial for a large electrical output.

Michael Faraday’s Homopolar Generator (chapter 13)

This design appeals to most people as it looks so simple. However, the problem is that most versions produce a very low voltage at very high current – potentially a thousand amps or more. Trying to come up with brushes which can carry high current for long periods of time without appreciable wear has proven to be a major problem. The Borderlands Science people discovered how to get an AC output from the device which allows the voltage to be stepped up and the necessary current reduced substantially. To date, I am not aware of anyone managing to produce a homopolar generator with a practical power input and output, but it is definitely a device which is wide open to experimentation.

The Romag and Mini-Romag Generators (chapter 13)
These designs call for construction with a range of different materials, and generally speaking, the materials used in any prototype are normally of major importance. Although these designs have been available for many years now, the only prototype which I have heard of is the 25 watt version built by J.L. Naudin, although there is probably not particular reason why the Romag could not be scaled up to produce a much larger output.

Nikola Tesla's Generators (chapter 11)
Neglecting the version which uses radium as that is probably difficult to obtain at the present time, the spark gap version is said to produce very substantial amounts of electricity while only using very simple components. I have never heard of anyone attempting to build one of these devices but in spite of the fact that we have limited information on the device, it seems like a very powerful unit which could well be extremely useful.

The Jines Permanent Magnet Motor (chapter 1)
This design includes magnetic shields and finding a suitable material for them might be a considerable problem. This design has to be considered to be fairly complicated due to the amount of mechanical work needed to construct the various mechanisms required for the motor.

The Annis and Eberly Generator (chapter 3)
This is a very clever solid-state generator. However, from the point of view of the home-constructor, producing their solid-state reluctance-switching material and it's controller would appear to be a major obstacle. Given that material and it's controller, many of the other devices would be exceptionally easy to build successfully.

The "Carousel" Permanent Magnet Motor (chapter 1)
This is a compact and very effective looking device but the very compact nature of it's construction probably makes it somewhat tricky to replicate. Anyone with good metalworking skills should be able to do it ok.

Devices which are unlikely to be practical

The Ecklin-Brown Generator (chapter 1)
People have had difficulty in making replications of this to work well. The biggest problem area is coming up with suitable magnetic screening material. It might be possible to adapt the design to use some of the very thin neodymium magnets instead of material which just screens the existing magnetic field. The Clemente Figuera design of chapter 3 is a better option.

Howard Johnson's Permanent Magnet Motor (chapter 1)
It appears that Howard has not been able to build replications of his original working prototype and while the theory is perfectly valid, that failure has to put a question mark against almost all permanent magnet motors of that type, especially since Mike Brady experienced exactly the same thing and Australian developers with a successful "Lutec" magnet motor found that they could not replicate it unless they used parts from their original prototype. The V-magnet system of the Hohl Motor in chapter 1 is an exception to this problem.

Mike Brady's "Perendev" Permanent Magnet Motor (chapter 1)
This design is in exactly the same position as Howard Johnson's Permanent Magnet Motor. It seems that Mike has experienced considerable difficulty in constructing working copies of his prototype. If you want to try to build one, by all means feel free.

Floyd Sweet's "VTA" Magnetic Generator (chapter 3)
Shown on video, producing more than 500 watts of mains output power for 1.2 milliwatts of input power, this is clearly a device of major importance. Unfortunately, we do not have Floyd's method of producing isolated and easily moved magnetic poles in a block of magnetic material and that is a major obstacle for the would-be replicator. I am not aware of anyone who has successfully replicated Floyd's device.

Oleg Gritsevitch's Toroidal Generator (chapter 5)
This incredibly successful and powerful device which produced 1.5 megawatts continuously for two years, took major equipment to get it started. It is not known if it can be successfully constructed in a smaller size and the coating between the water in the toroid and the toroid casing may be difficult to achieve.

Tariel Kapanadze's Electrical Generator (chapter 3)
Unfortunately, Tariel has repeatedly refused to reveal how his designs operate. He has also been involved in several very questionable business deals where the other party felt cheated. It is most unlikely that he will ever reveal the details. Replicating it is not really a beginner's project and an overunity.com forum has been trying to replicate it for a long time now.

Hans Coler's Devices (chapter 9)
The passive design of Hans Coler can certainly be made to operate if you can persuade it to begin oscillating. The output is quite small but interestingly, it does demonstrate that we are indeed surrounded by energy which can be tapped for practical purposes. This device needs patience in order to get it going.

The Meyer-Mace Isotopic Generator (chapter 3)
I have never heard of this design being replicated. It calls for a 21 MHz generator which is quite a high frequency for the home constructor. The design itself is certainly simple but getting it to work if it doesn't function initially is not likely to be easy. The Nuclear Magnetic Resonance involved is explained by William McFreey in chapter 3.

Ed Gray Power Tube (chapter 5)
Ed Gray's power tube is unlikely to be COP>1. The genius behind his achievements was Marvin Cole whose ambition was to be a chef. Marvin built a motor which was certified as COP=237 by Cal-Tech's independent testing, but when he disappeared from the scene, Ed was left at a bit of a loss. Ed only produced patent applications in order to reassure his investors and he never wanted to disclose anything of worth. Mark McKay's detailed information in the Appendix provides extensive background and Mark has now written a book on the subject.

Roy Meyer's Aerial System (chapter 7)
I know of only one person who tried to replicate this design. The first time he tried it, it worked ok although it was not aimed in the 'right' direction, but he was never able to get it to work again. So it appears that while the design may well work, it is not easy to replicate and get functioning.

Karl Schappeller's Device (chapter 11)
To be perfectly honest, I have never managed to understand the work of either Karl Schappeller or that of Viktor Schauberger. Not properly understanding the design makes me believe that newcomers to free-energy construction work would have difficulty with this device. That may well be an unfair assessment and if you are able to build and use this design, then please explain it to me so that I can document it properly.

The "HydroStar" and "HydroGen" devices (chapter 13)
These designs have been around for a long time and to date I have never heard of anyone who has managed to build one and got it to work. In theory, they are supposed to allow a car to run with water as the fuel. On the surface, I can see no way that that could happen unless it operates as a version of the Joe Cell, which it very well may do. If that is the case, then great patience will be needed before the vehicle will operate. I would not recommend anyone to build either of these designs.

Francois Cornish's Aluminium-feed System (chapter 13)
This system is not economical in the broad sense in that it takes more energy to produce or reform the aluminium than is given out when it is converted to oxide in the process which produces hydrogen for combustion. It can be economical for the user in that the processed aluminium is less expensive than oil products. However, the oxide residue generated by the process limits the effective applications for the process as a whole. It is not a good constructional project.

The Motionless Electric Generator ("MEG") (chapter 13)
This is a device which most people find very difficult if not impossible to get to COP>1 operation. If the frame is made of Metglas nanocrystalline material, then it might be possible. However, the design has been around for a decade and it has not (yet) made it to commercial production, so I would suggest that this is a device which is not a good choice for a constructional project.

Devices which are not really possible

The ShenHe Wang Permanent Magnet Motor (chapter 1)
While there is a patent for this design, there is not enough information for there to be any reasonable degree of success if you were to try to replicate it. For that reason, it probably should not be considered as being a viable construction project at this time. It may well become available commercially at a later date.

Thomas Henry Moray's Aerial System (chapter 7)
While this device is, without question, a most impressive device which was demonstrated in public on many occasions, Thomas was intimidated and so never released full constructional details of how his device worked. That lack of specific information prevents this from being a realistic constructional project.

Steven Mark's Toroidal Power Unit ("TPU") (chapter 5)
While this unit has been demonstrated on video, showing impressive operation, I understand that it overheats after 22 minutes of operation. That is not a major problem and could be overcome, but the lack of specific constructional or design information makes this a research project rather than a normal constructional project.

Paul Baumann's "Thestatika" Generator (chapter 13)
The late Paul Baumann designed and built several self-powered generators which were demonstrated on many occasions. These are still in the possession of a Swiss religious commune who refuse to release the details as they think that "the world is not ready for this information". The lack of the vital design information makes replicating the device a non-starter which is a great pity since it has a substantial mains power output which could ease suffering around the world.

Muammer Yildiz's "Ocean Star" Generator (chapter 13)
While the demonstration of this device looks quite like a hoax, Muammer's credibility jumped massively with the production of his current permanent-magnet-only motor which has been demonstrated publicly. The "Ocean Star" device was supposed to be able to power a house, but the patent information is not nearly clear enough to deduce how to build the device. Perhaps somebody could ask Muammer to explain it in more detail and disclose the key design details in order to allow home-built replications.

Topic: Electrolysis

Question:
I was reading the D9.pdf file you put together on Bob Boyce's electrolyser and PWM3G circuit. The close up picture of the PWM3G circuit shows only 5 LED lights but below under the ***Testing the Completed Board*** section it talks about 8 LED lights. also on the animated picture (the one with all the components on the board) there are 8 led lights. did bob build another type of board with fewer LED's on it? If so could you explain how to test the different board? Also I was considering buying the board from the Hydrogen Garage website, would you recommend this?

Answer:
The D9 document was created long before the 3G version of the board was produced. The version shown in the document is only there to give an impression of what the board was like at the time. Bob has always been reluctant for any specific details of his circuits to be published which is why the circuit schematic is not shown in the document.

The supplier of your board will tell you how to tune it. I would not expect it to be a different method. Essentially, you start with the frequency variable resistors in their central position and the Mark/Space resistors set to about 10% On time. Then you tune the top frequency of 42.8 kHz to give the best gas output. You then adjust the middle frequency to give the best gas output. Finally, you adjust the lowest frequency channel to give the best gas output. The Hydrogen Garage in the US or Courtierstown Marine in the UK can advise you.

The Hydrogen Garage is run by a very honest and reliable electrolysis enthusiast with many years of practical experience behind him, and there is no reason why you should not buy from there if you want to.

Question:
OK, so if I want to build one of those boosters and I have 14.8 volts in my car how am I going to power 18 plates 5" x 4". That's the only thing that's confusing because there would not be enough voltage

Answer:
I'm not sure where the idea of 18 plates came from. It is likely that your electrics give 13.8 volts rather than 14.8, although that is not critical in any way.

You are aimed at seven cells in a chain so that each cell gets about 2 volts across it. If you put partitions in your box, then with your proposed current you would use just two 5" x 4" plates per cell - a total of 14 plates. If you wanted to provide more plate area, then you would use three plates per cell, making 21 plates.

However, if all your journeys are short and the cell will never get up to its full temperature due to the short time it operates, then you could go for just six cells and with three plates per cell and that would make 18 plates.

If you use separate plates, then you have the difficulty of making good-quality electrical connections between six pairs of plates, and that can be quite difficult to do. I would suggest that you consider the bending method shown at the start of Chapter 10 as that overcomes the need for making any electrical connections inside the cells.

The best plate performance is with two to four square inches per amp of current. As only bending is involved, it would pay off to have a generous plate area, especially if you are using mesh. Mind you, the mesh surface area is not much reduced by the holes as the surface around each hole as it passes through the thickness of the plate is also active. The hole edges are also very helpful in getting the bubbles to break away when the cell is new. Later on, when the cell is conditioned, the bubbles will not stick to the plates at all.

Question:
Is it possible to generate electricity using hydroxy gas?

Answer:
Yes, it is perfectly possible to generate electricity using hydroxy gas:

1. Take a standard electrical generator such as a Honda 6.6 kVA V twin or a Vanguard V twin.

2. Adapt it by filling in the timing key slot and cutting another which lets you set the spark timing to two degrees after TDC.

3. Build any electrolyser capable of producing 5 lpm of hydroxy gas.

4. Feed the generator air, hydroxy and cold water mist from a Venturi tube, pond fogger or miniature carburettor.

5. The generator can run well on that and produce kilowatts of excess electricity over and above the amount needed to power the electrolyser.

This has already been done on at least nine different generators and run 24 x 7 for two and a half years now. However, please be aware that generator engines wear out eventually and will need a rebuild or replacement, so the electricity produced is not "free".

Q: What mmw (efficiency) rating of hydroxy generation is need to achieve this? Also, is it necessary to be using some type of resonance system or will brute force/catalytic electrolysis work?

A: You can use any type of electrolyser you like. Unlike the alternator in a vehicle, a generator is designed to put out a major amount of electrical power on a continuous basis. So, if you take half a kilowatt or more generating the hydroxy, who cares? If the generator is called a 5.5 kW by the manufacturer and you wish to run it at 4.5 kW assuming that the seller is being generous with his rating in order to compete with other brands, then if you use 0.5 kilowatts (12V at 40 amps) for electrolysis you are definitely in business. The two makes of generator quoted, have proven very reliable in long-term use. The addition of very tiny cold water droplets is a key factor in making this work.

Question:
Do you know if the V-twin Vanguard and Honda generator you have mentioned, do not have the waste spark? I would like to buy one, but need to make sure before doing so.

Answer:
The people who have done these conversions say that retarding the spark to 2 degrees after Top Dead Centre was sufficient. Never having worked on internal combustion engines, I can't personally confirm it myself from my own experience.

If you decide to do it and are successful (as I would expect), then I would be happy to produce a document for you which would go out under your name. If you decide to do that, then please take photographs before, during and after your filling in of the timing key slot and the cutting of the new one as that is one item which would benefit from having detailed pictures. Supplier details for the cold water mist device which you pick, be it pond fogger, Venturi tube or miniature carburettor, would be helpful for others following after you.

Question:

Do you have any values for Peter Lowrie's coils, the ones mentioned in the doc are "from a commercial installation with copper sheet wrapped around them" as it is my intention to use a Marine alternator.

Answer:
There are two different techniques for producing hydroxy gas:

1. Pulsed DC signal which can reach 1,200% Faraday.

2. Brute force DC which is usually less than Faraday although with great care, it can reach 212% Faraday.

Peter Lowrie used a marine alternator solely because he wanted three separate 2-volt supplies at 900 amps each. It was because of his very high current that he used an industrial 3-phase power supply choke. Unless you are aimed at currents that high, then you definitely don't need chokes of that massive current capability.

If you are determined to use a similar item, then you need to look at the spares options for professional, commercial equipment. Peter only used a marine alternator for its very high current producing capability and he told me that a second-hand truck alternator would do just as well.

Question:
You said...

"When that gas is added to gasoline droplets in a gasoline engine, it acts on those fuel droplets during the compression stroke, breaking those long chains of hydrogen and carbon atoms into shorter, more active fragments of chains. This produces more active and better combustion of the fuel when it is ignited by the spark, and that extracts more energy from the gasoline, energy which would have been wasted in the catalytic converter and in producing unwanted excess heat in the engine".

This is the first time I have heard that the Hydroxy is doing something BEFORE it is ignited. I thought the Hydroxy ignition was what was breaking down the gasoline into short molecules? Can you explain this more?

Also, can you email me here or privately what you feel are the best Free Energy Devices these days. I think many may be interested in Free Energy Devices to drive their electrolysers. I'm interested in the devices themselves. Also, is anything near to coming to market?

Answer:
On 14th January, Bob Boyce's post to his Hydroxy forum included the statement: "When either hydroxy gas, or HHO, is compressed in an engine cylinder, it is after it has been diluted with intake air, as well as fuel in non-diesel engines. Not only does the dilution in air raise the auto-ignition pressure, but in non-diesel engines the orthohydrogen has already bound to the long hydrocarbon fuel chains and broken them prior to compression. As this bonding occurs, orthohydrogen decays to parahydrogen. It is the energy from this decay which breaks the hydrocarbon chains into simpler hydrocarbons. These simpler hydrocarbons combust much more efficiently and completely. With diesels, the process is slightly altered, as there is less time for bonding to occur, so improvement occurs much better at lower RPM than at higher RPM".

Gasoline molecules vary from chains of seven carbon atoms surrounded by sixteen hydrogen atoms, to chains of nine carbon surrounded by twenty hydrogen atoms. These chains need to be broken down in order for those hydrogen atoms to combine with oxygen atoms from the air in the cylinder, to produce the heat and expansion which powers the engine. That is why the spark is generally about eight degrees before Top Dead Centre, giving time for this to happen. The more broken up those chains are before the spark, the better.

With regards to free-energy devices, I get asked on a regular basis, what device is best for somebody to try building. The question always comes without the relevant details needed to even make a rough guess at a realistic answer. There is generally no information on country, skills, tools, finance, workspace, time available, main objective, local materials available, environmental space, etc. etc.

Obviously, if someone has converted a pick-up to electric operation and could put a water-fuel generator in the back, the kilowatts of excess electrical power would extend the battery range substantially and would recharge the batteries during a meal break or while away from the vehicle.

This chapter is an attempt to answer your question as to what devices you might choose to attempt to replicate. There is massive opposition to any free-energy device being brought to market. Shenhe Wang intended his permanent magnet motor/generator design to be given freely to all countries in the world. I always felt that he had to be completely unaware of how governments who get billions per year in oil taxes and utility company taxes, would view such a venture, not to mention the oil companies who would see their massive revenue stream being threatened by the introduction of a small device which can output kilowatts of electrical power without using any form of fuel. At this time, it appears that Shenhe's generator is being restricted to China, which hardly comes as a shock.

Chas Campbell in Australia has a viable, commercial machine which also produces significant power without the need for any fuel. He can't find anyone interested in manufacturing it and his local power company just doesn't want to know. However, there are several devices which are nearing being brought to market at this time, and I would expect to see them in use early in 2013.

Question:
I have bought a 7-cell, series-connected electrolyser but the terminals are not marked for Plus and Minus connections. Does it matter which way round it is connected?

Answer:
Any series-connected electrolyser will operate well when connected either way around. However, there is an effect if the unit has already been run. If you are aiming for the top level of efficiency of DC electrolysis, having prepared, cleansed and conditioned the plates with Bob Boyce's methods, then the plates will have been conditioned with the current flowing in one direction. If the direction of current flow is reversed on Meyer type cells the conditioning reverses, the performance drops off and then the conditioning rebuilds, bringing the performance back up again. I am reasonably sure that the same thing happens in a Boyce conditioned electrolyser, so if at all possible, try to identify which way round the unit was originally connected and keep to that direction of current flow.

Question:
In Bob Boyce's electrical diagram, it shows three heavy-duty chokes: one from the rectifier bridge positive, one on the negative and one from the positive line to the circuit board. My question is: "what is the value or specification for these chokes and where can you find them?"

Answer:
There is a document called "D9.pdf" which provides the details of Bob Boyce's resonant electrolyser design. On page 30 of that document, immediately under the circuit diagram it tells you the choke core, the supplier of that core, the wire used to wind the choke and the number of turns to be wound on the core.

Question:
What size hose would be required to run a V-8 on all hydroxy? Does anyone have a flow chart for gas, or know were to find/get one?

Answer:
It is not possible to answer your question directly as we don't know what rate of gas flow you think would be needed or how long the pipe has to be. There is a table of pipe sizes for various gas flow rates on the web site:
http://www.engineeringtoolbox.com/natural-gas-pipe-sizing-d_826.html and as 1 cubic foot per hour is about 0.15 litres per minute, if you were feeding the engine 150 lpm, then the table entry would be 1000 cu. ft./hr. and you would be looking at the nominal pipe size of 1.25 inch inner diameter. My guess would be a 1.5 inch pipe as the less restriction to gas flow the better. If you want to get a feel for the capacity of any particular diameter of pipe, then try blowing through it. The results are surprising and a small pipe around a quarter of an inch in diameter (6 mm) is incredibly difficult to blow through in spite of looking like an easy gas-flow path.

The amount of gas needed for your engine is reduced massively if you add cold water mist to the intake air. Nobody can answer the question for you because engines vary so much. Even supposedly identical engines have very different gas requirements, so you really need to experiment with your engine to discover what it actually needs. There is some cold water mist information in Chapter 10.

Q: Thank you for that chart, it's just what I was looking for. Now that I know what size of pipe can carry any particular gas-flow rate, I guess the real question is "how many lpm would it take to run a 318 cubic inch Dodge motor?" I read somewhere that it takes 80 litres per minute per 100 cubic inches of engine capacity. I may have got that backwards. Any thoughts?

A: Unfortunately, there isn't any fixed answer to your question and you definitely can't use a rule of thumb to get a reliable answer. Using cold water fog from a pond fogger reduces the amount of hydroxy gas needed by a large percentage, so try reading Chapter 10 which explains this. You need to understand the operating principles if you are to be successful. Also, you have a much easier task if you start with an engine which is much smaller in size, so I suggest that you begin with an electric generator of about 6 kilowatts as described in Chapter 10 before trying to run a very large engine of 318 cubic inch capacity (5.21 litres), which is about twenty times more difficult.

Question:
I am trying to make different devices in order to improve gas mileage on my car. However, I have some difficulties in understanding the automotive circuits. Could you, please, help me?...

I found in Tad Johnson's experience this: "What I found frustrating is that the cell temperature would change and the system would stop making gas. In order to keep the system making gas you constantly have to keep the cell in resonance, and thus you really need the system to be controlled by a processor, that constantly checks frequency on both legs and then adjust inductance to keep the cell in resonance. This is why Stanley moved to the other patents where the spark plug type of electrolysis chamber was used instead of a large cell."

In this case you gave me a clue in this paragraph: "A John Bedini pulser circuit can be used very effectively with a cell of this type and it adjust automatically to the resonant frequency as the cell is part of the frequency-determining circuit."
First, I didn't find in your book a Bedini pulser circuit so please give me direction where I can find it.
Second, in Stan Meyer's large cell, I understand, we have two kinds of resonance. One resonance is in an LC circuit where the "C" is the cell itself and the coil is the "L". This is electronic resonance. Another resonance is mechanical resonance where the tube pairs vibrate at the same frequency as the electronic circuit (or a harmonic of that frequency). In this case if I make a device to check the current of the cell, this device can adjust the frequency to be identical with the frequency of the tubes, because the current is in direct relation with resonance. If I am wrong, please let me know.

In your book there is a quotation which says: "I plan to market a pre-programmed chip capable of making any hydroxy system work. While I plan to have a profitable venture with the professional pre-programmed architecture, I also believe in the open source do-it-yourself community, which is where I got started. The chips I plan to sell will be a 'plug and play' device. You send me the info on the type of vehicle you are modifying, and the efficiency data of your cell, and I'll be able to send you a chip that will make your ECU work with those conditions. The Do-it-yourself version would be quite time consuming but, would work for less than one quarter of the price." I may be interested in buying the chip if you let me know the price before I order it.

Answer:
Tad Johnson used 1,200 volts and was able to get 3 lpm of hydroxy gas at just 1 milliamp of current (1.2 watts) but he found that he could not scale it up for greater gas output.

Chapter 10 has a circuit which finds and holds a cell on its resonant frequency and that circuit will be available ready-made from Courtierstown Marine in the near future. The Stan Meyer "Water Fuel Cell" has been replicated by Dave Lawton of Wales and the full construction details are in Chapter 10. Further advances have been made by Dr Scott Cramton who is getting 6 lpm on just 12 watts of input energy (plus the waveform from the generator which he is boosting - probably 36 watts overall - 12 volts at 3 amps) and who can reduce the diesel requirement of any diesel engine or generator by 60%. Chapter 10 also shows how to run an electrical generator on water alone.

The ECU piggyback chip details are found in the http://www.free-energy-info.tuks.nl/D17.pdf document and it is Les Pearson of the USA (lespearson@hotmail.com) and not myself who is dealing with piggyback chips. I am located in the UK and European vehicles have a completely different computer control system to the ECUs of vehicles in the USA.

Question:
My project is to deliver HHO to a Mazda turbo rotary with 13 lbs boost. I'm not comfortable about injecting HHO into the low-pressure side of the turbo. Even thought it's mixed with incoming air, the turbo radial scroll is a wicked device with lots of sharp blades and turbulent flow. The discharge air at full power can reach over 300 degrees Fahrenheit and easily exceed the 13 lbs boost to compensate for losses. This pressurised air charge is sent to a double-pass intercooler before going on to the manifolds. A violent, hot, and long path. If the HHO survives the journey it has definitely reverted to diatomic.

I need to know what to expect if the HHO can leave the bubbler/dryer and move directly to a diaphragm compressor (premixed and diluted with air, if necessary) for direct port injection at 20 psi. What data are available to show auto-ignition at 15 psi? What temperatures, concentrations, method of compression, etc. If I can't up the delivery pressure for direct port injection, I might consider stopping development of my prototype. Please, there must be a safe way to do this???

Answer:
This subject has come up several times on the different forums and the experienced people recommend putting the hydroxy in on the low-pressure side of a turbo-charger. The hydroxy gets heavily diluted by being mixed with the incoming air and so its characteristics change before it reaches the potential trouble spots which you mention. I am not an automotive expert and so can't make any useful comments from my own experience.

One or two people have tried putting it in on the high-pressure side and have found it ok, but it is distinctly possible that their hydroxy gas was low-grade and already laced with hot water vapour, lowering it's energy level and potential hazard, so my money is definitely on the low-pressure side.

The self-ignition at 12 to 15 psi information comes from Bob Boyce who is easily the most experienced hydroxy user and investigator on all of the forums. That figure relates to Bob's hydroxy which is the highest possible quality and most people never manage to get anything as high-energy as Bob's gas output. The information comes from repeated experiments by Bob who just lets the pressure build up and then notes the pressure at which it explodes inside his container which is strong enough to withstand the explosion.

Q: Thank you for your quick reply. I am due to meet with Bob Boyce next week. I hope he will have the time (and patience) to deal with my newbie questions but I intend to drill down on this turbocharger thing. For my project, it's mandatory that I run with a turbo, and mandatory that I can feed the maximum amount of high quality HHO. This engine will be developing 400 hp with 13 lbs boost. I think I'll be defeating my purpose if trying to push maximum amounts of HHO into the low pressure side of the intake. First, it will partially displace the necessary air for combustion. Second, it has a torturous route to travel. Third, it will no longer be monatomic HHO when it finally reaches the engine. There must be a better way.

That's why I was hoping to experiment with a medical diaphragm compressor (same as they use to store hydrogen). If I can blend some outside air with the HHO prior to compression, maybe Bob can tell me what ratio of air/HHO to offset/raise the self-ignition. I'm only looking for 20 psi so maybe the dilution won't be a big deal. Anyway, I'm trying to maintain the purity of the HHO prior to engine combustion.

A: Bob Boyce, who is a very highly experienced hydroxy researcher, states categorically, that you should use the low-pressure side of the turbocharger. I am reasonably certain that there is no need for you to pre-mix the hydroxy and air as that happens adequately during the normal intake process, but Bob can certainly give you much more specific detail on this than I ever could. The pressure for self-ignition is raised enormously when the hydroxy is mixed with air, so it should not be a problem in your case.

The objective is to extract a higher proportion of the energy contained in the normal hydrocarbon fuel, and not to add in energy produced by the combustion of hydroxy gas. That being the case, the amount of hydroxy does not have to be enormous for there to be a very significant gain in engine power and thrust quality. Again, Bob is the man to give you the specifics. Good luck with your project, and I hope your visit to Bob works out well.

Question:
I'm spending my day watching YouTube videos of Bob Boyce. It seems every minute I'm learning more and more. Big problem for me is (-40) cold weather and freezing of the water when not in use. (Canadian winters are brutal). The bubblers can be filled with KOH, no problem there. Same with the main cell if I use KOH. But the biggest problem is the water reservoir and supply lines. I had thought of 50/50 blend of methyl hydrate/water (windshield washer fluid) but, according to one of Bob's videos, the carbon will bond with the nickel in the stainless steel plates and eventually stop gas production (sigh). If I had a consistent and reliable electrical power source, I could just plug in a heater of some fashion, but I won't always have that luxury. Any thought on the subject??

Answer:
Please do NOT put KOH in your bubblers as a major function of the bubblers is to wash all traces of KOH out of the gas before it reaches your engine as traces of KOH are not good for your engine. You can use alcohol or paraffin ("kerosene" in the US) which many Canadians have found satisfactory in bubblers as the fumes are not harmful to your engine in any way. If you are boosting, then the water usage will be so low that you can manually top up with warm water from time to time.

Question:
I have watched the interview of Bob Boyce with Chris Patton countless times, even now, looking for signs of 'bullshit'. I have a good intuition which I trust and listening to Bob I can't help but like the guy and still believe every word he says. I'm a plumber and have no previous experience with hydrogen. I've built a 101 plate

electrolyzer following your plans and I'm getting 4 lpm when using 190 volts DC and about 4 amps of current.

I've wound my toroid and just run out of money for a scope to try to get the resonance. I've noticed that no one seems to have ever replicated what is described on your website and that Bob is copping it on the forums. I believe him still, but I was wondering in your opinion why is it that no one has managed to get 50 lpm or anything mind blowing? Where could the problem be? I'll tell you one thing though, I'm gonna keep at it as soon as I can afford a scope.

Answer:
Resonance is very important in any COP>1 system, which is what Bob Boyce's hydroxy system is. I'm not sure about your need for an oscilloscope, but don't let me discourage you from getting one. If you have not seen them, the series of YouTube video clips on resonance http://www.youtube.com/user/gotoluc#p/u/15/L0AZkovLTT8 should be both interesting and helpful.

Dave Lawton has designed and tested a circuit which finds and locks on to the resonant frequency of his style of cell. That circuit is available as a pcb, a kit, or a ready-made unit from Courtierstown Marine in Aberdeen.

However, Bob Boyce's design calls for three drive channels instead of just one. Bob has designed, built and tested what he calls his "Hex Controller" which is probably a PIC chip programmed device. He has kept it secret while he applies for a patent on it, but it should become commercially available shortly. I understand that like Dave's design, it locates and locks on to the resonant frequency of the cell.

When not tuned to resonance, the pulsing system should give about three times the gas output of the DC cell performance. When tuned to resonance, the increase should be five or six times.

As you are probably aware, the electrolyser needs to have the plates cleansed and conditioned as described in the D9.pdf document on Bob's unit. Then the cell needs to be "run-in" on DC until it gives around twice the Faraday output. After that, the unit is filled with 28% by weight KOH electrolyte and fed the pulsing signal.

Faraday defined electrolysis as being 2.34 watts per litre per hour of gas output. That is 2.34 x 60 = 140.4 watts for 1 lpm of hydroxy. At this time, you are feeding in 4 amps at 190 volts which is 760 watts. For that 760 watts Faraday would expect 5.41 lpm, which means that your unit is running at 74% Faraday, or about one third of the expected output from Bob's design before it is ready to go to pulsing operation.

Admittedly, the 190 volts is fractionally low for 100 cells, but it is close enough not to be any problem. So, at this point in time, your cell needs mechanical attention in order to get up to the 11 lpm or so that can be achieved on DC alone. When it reaches that level of performance on a 10% NaOH solution, it should then achieve 33 lpm or more with untuned pulsing. But the first step is to get the cell to it's necessary DC performance level, which, unfortunately, probably will need the plates to be prepared to a higher degree.

Unfortunately, there is a difficulty with Bob's design and that is that the plates need to be positioned and sealed to a degree well beyond the capabilities of the average person to construct. If you bought your case from Ed Holdgate, then there will be no problem, but a home-made case can't generally be constructed to the necessary 1/3000 inch accuracy by the average person, as that is a skilled job for an expert machinist who needs to know the exact, actual electrode plate thickness before he starts making your box.

The need for that extreme accuracy is because the resonant operation sets up a magnetic waveform inside the plate array and that won't happen unless the plates are positioned VERY accurately. The gas bubbles form in the electrolyte between the plates rather than on the plates and when that happens it looks like the electrolyte is boiling although it is actually quite cool. I'm sorry that my reply has to sound so negative especially since you will already have put in a large amount of effort on your project. Good luck with your upgrades

Question:
You must be busy, but I'd appreciate any feedback about this link:
http://www.pureenergysystems.com/news/2005/03/17/6900069_Acetone/ Would you say engines in good condition get improvement, or the opposite? In you opinion, could I damage a diesel tractor engine, or car gasoline engine by trying small amounts of acetone added?

Answer:
There was a lot of discussion about acetone some years ago. Some people got around 20% mpg improvement while others got no improvement at all. It appears to depend on the engine and the condition that the engine is in when the test is run. You need to understand that I am not an automotive expert and so my opinion does not count for much. I would expect it to be the older and poor-condition engines which would benefit most from

acetone - which, incidentally, is a fairly dangerous substance for humans and needs to be handled with considerable care as it can be absorbed through the skin and by inhalation and it can cause kidney damage.

I don't think that you will damage any engine by adding some to the fuel. Having said that, you can get up to 60% fuel reduction on a diesel engine by adding hydroxy gas in sufficient quantity and petrol engines respond even better than diesels. The GEET device allows a major reduction in fuel use and is very popular in France where many tractors use it. The http://www.panacea-bocaf.org web site has a good deal of information on it and are experimenting with it at this time. There are also two GEET enthusiast forums.

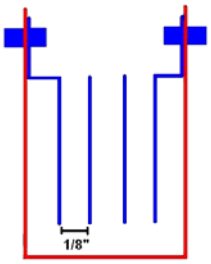
Question:
I have a Ford "Transit" diesel 70 hp manufactured in 1995. Is it possible to add hydrogen in order to let it run with less fuel consumption and be more environmentally friendly?

Answer:
The fuel consumption of a diesel engine can be reduced by anything up to 60% by adding hydroxy gas to the incoming air. As far as I am aware, no modification to the engine is needed. The improvement in fuel consumption is proportional to the amount of hydroxy gas added. I hope that this helps and good luck with your project.

Question:
Hello, we need your help. Based on your 6-cell model of Chapter 10, we have built such a generator, which is as follows:

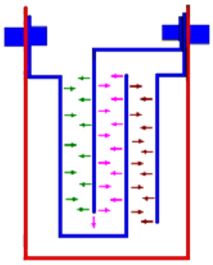
- Stainless steel type 304 (do not get the 316), calibre 0.08.

- Badges 4 "1 / 4 X 2", 4 plates per cell, total 24 plates (206.4 in^2).



NaOH was used as electrolyte, with a concentration of 20% (as described in chapter 10), we just apply 13.5v a current consumption of 1.5A. We use a higher concentration of electrolyte at 30%, 40% and gave us the same result with a current consumption always similar to 1.5A. We need to know because consumption is so low that, according to calculations based on Chapter 10, current consumption with 12V, it should be up to 40A. Or have we miscalculated? See attached image.

Answer:



You have invented your own plate arrangement which needs 6 volts per cell because you have 3 (very inefficient) voltage gaps inside each cell. At this time, you are applying only 0.7 volts between each pair of plates and that is why the current does not change much with stronger electrolyte. You need to change the plate arrangement to what is shown in this drawing. Good luck with your project.

Question:
In the WaterFuel1978 Yahoo forum, the contributor "s1r9a9m9" says that he runs his large capacity car which has 8-cylinders, using just water and an inverter. Do you know of anyone who has replicated this?

Answer:
I am reasonably sure that Nathren Armour is a professional con artist, paid to mislead people investigating how to run an engine on water. "s1r9a9m9" (Nathren Armour of the USA) came on the scene about four years ago. I didn't believe him at all, so I asked him some questions by direct e-mail. I was very surprised when his answers were quite convincing. This was in the old "egaspower" forum. So I wrote a document drawing together all that he had said about the design and adding in each relevant post by people in the egaspower forum who tried to understand and build his design.

After two years of intensive experimentation by several competent people, there was not the slightest success by anyone. Because of this, I withdrew the document "D13.pdf" (although there are probably copies still floating around). I no longer believe that anything Nathren says now, or said back then, is true. In the early days, he posed as an uneducated country car mechanic, who for some unknown reason, was asked by NASA to make some component for a mission to Mars. Why NASA should rely on a country car mechanic is not at all clear. At that time, he told me in a direct e-mail, that he had converted his own personal car, and the engine out of a truck which he used to power an electrical generator, and the cars (plural) of his friends.

His car has 8 cylinders, the truck at least 4 (though probably more), at least two friends with four cylinder cars, makes a minimum of 20 relays needed, plus one which he took apart to see how it was made, so say 21 although 27 would be a more likely number. When writing at that time, his posts were written in broken, uneducated English with a space before the full-stop at the end of each of his sentences.

Now, his posts are in much better English, the gap before the full-stop has gone and the relay count which he states, contradicts what he told me by a really major factor. He no longer allows for the relays used for his friend's cars, or the one which he supposedly took apart. Any time he was asked for specific information, he always made unconvincing excuses and supplied no worthwhile data.

He has posted videos of the Steorn device, showing bench test equipment of a type which no country car mechanic would ever own or understand. His videos have sound but he does not say a single word, which is most unusual for an English speaker, and in this case is highly suspicious.

My opinion is that his information is wholly fake. It is distinctly possible that this con is now being carried on by a second fake "Nathren Armour". I have never heard of anyone managing to replicate any part of his supposed invention, and I doubt that anyone will ever manage it, although I would be delighted to be proved wrong.

It is perfectly possible to run an engine of any size on what appears to be water alone (the engine actually runs on stored energy drawn directly from the local environment, coming mainly from our Sun). I know of several "petrol-powered" electrical generators which have been converted to run on water in spite of the fact that the efficiency of their tiny internal combustion engines can be as low as 10%. Some of those generators have been running continuously for more than two years now.

Running a large engine on water alone is a much more difficult task but it can be achieved by the energising and injection systems of Stanley Meyer. Sorting out a system of that type has been quite difficult as Stan developed many different types and styles of adaption and it was not immediately clear to me, which of his descriptions apply to which of his systems. Additional information from the contributor whose ID is "H2Opower", has been most helpful, and Stan's design is now much more understandable, which means that replications are now a distinct possibility.

Question:
My daughter came to visit from California. She got 27 miles per (US) gallon average on the trip up here with her Buick Regal. For her return trip with a full car load of her stuff I installed an improved (single water bath) electrolyser, current control with a BASIC Pulse-Width Modulator, and I made her a MAP sensor enhancer override. She followed the same route back to California and averaged just under 40 miles per gallon (a 45% increase). No other changes were made. The electrolyser has eight 2.5" x 5" stainless steel plates with 1/8" spacing in a Mason jar. The plates were all cross-hatched with sanding score marks and all skin oils were removed with trichloretheleyne (Automotive Brake Parts Cleaner). I used the method Boyce recommended of polarizing the plates with a wire wrapped around the body of the plates and sparking across a 12 volt DC source. I set the Pulse-Width Modulator to supply 18 amps steady once warmed up. Previous to this project the best I had achieved is a 23% increase. Your book helped me to tweak a few things and waah-laaaah 39+ mpg.

I do have one problem which I've been trying to figure out. I am building a Don Smith type device. The unit he showed is rated at 8,000 volts at 20 amps (160 KW). I used a 10 foot section of #12 solid copper wire for the L2 coil wound around a 2" pvc pipe. I then released the hold on the wire allowing it to expand to approx 3"diameter coils. Then I cut four ABS plastic strips and hot glued them into the interior of the coil spaced evenly. The coils are spaced at 3/8" space per turn. I then used insulated #12 multi-stranded (maybe 50 strands) wire 2.5 feet long for the L1 coil wrapped around a 1.5" PVC pipe which made about 5 and 1/8 turns. the excess wire was run through holes into the centre of the pipe and carried through to near the lower end to exit the pipe and was then led to the terminal strip for the neon generator.

The neon generator throws a 2" spark until it is hooked to the coil. Once the L1 coil is hooked up I can't get the slightest spark! The spark gap will not arc even a 64th of an inch. I've tried rectifying the output of the neon transformer and tried direct hook-up. It seems odd to expect that a spark could be drawn with the L1 coil direct shorted across the transformer output. My understanding is that the spark gap is required to maintain the frequency as a trigger when DC is used, but that it is not absolutely necessary with AC. Is this your understanding? I know from Tesla's drawings that he commonly used them, but often it was after a capacitor.

When I was looking at the photo clip of the device I didn't see any diodes. Could they be in the black insulating tubing on the terminal strip? Do you know why he converts to DC before he goes into the coil, when he again rectifies with a bridge after the L1 / L2 coil assembly? Could he just as well be using AC until he completes the zero-point energy collection process like Tesla often did or are you positive he has diodes in there at the neon transformer?

One last thing... Do you know how I can read the frequency of the neon's High Voltage High Frequency output with an oscilloscope? I tried to contact the sellers of the devices and they have no idea what the frequency of the output is. They just read what the data plate says on input frequency. I am now trying to get the info from the manufacturer, so far unsuccessfully.

Answer:
May I suggest that you hold off on your assessment of the improvement in mpg got by your daughter. Some ECUs are programmed to adapt to changes such as the addition of hydrogen, and after a few days or weeks, revert to pumping in excess gasoline. Let's see what the effect is after some time has passed. Certainly, the improvement achieved so far is a good indication of what is definitely possible in spite of the opposition from the ECU.

I'm afraid that the suggestion on wrapping wire around the plates and pulsing it, came from me rather than Bob Boyce, who I understand thought that it was a ridiculous idea until one electrolyser builder told him that he had got a substantial percentage gas improvement by doing that. In theory, if the steel is perfect, then it would have no effect, but if, as can happen, the steel supplied is not perfect, then it could help, especially in the early stages of electrolysis.

The devices described by Don Smith are probably the most difficult you could try to replicate (with the possible exception of the Joe Cell). Each of Don's devices need to be tuned to resonance which is difficult to do unless you have a lot of patience, equipment and know-how. Your construction method sounds great and your choice of materials, very good - most people ignore what they are told and decide to do something else and then say that "it doesn't work", while in reality, they should be saying "I couldn't get my altered design to work".

In my opinion, the spark will not occur unless you have a capacitor across the L1 coil, forming an L-C combination which has high impedance at the frequency produced by the neon driver circuit. On it's own, I would expect the L1 coil to load the neon supply too heavily to get any serious voltage across it. As an L-C pair, the impedance at one particular frequency will be very much higher (which is how an AM crystal set radio receiver tunes in a particular station). The spark will only occur at resonance as the voltage will be pulled down too low at all other frequencies.

The diodes are hard to see in the video. They are long and black and don't show up well against the dark background. There are actually four of them on the output side and as you correctly remark, Don describes them as a bridge. They are very long because of their high voltage rating, perhaps ten times as long as they are wide.

I think that the neon driver which Don had, gives two separate high voltage outputs and Don combines them on the input side of L1 with two diodes to stop them interacting with each other. Your neon driver circuit is liable to be very different to Don's.

The frequency and shape of the neon driver output pulses can be read with an oscilloscope. You set the horizontal time adjustment so that you have two successive pulses widely spaced on the screen, and then the horizontal timing setting combined with the number of squares on the screen between the start of each pulse shows you how far apart in time the pulses are. If the time between them is 0.033 milliseconds, then the number in one second (which is the frequency) will be the number of 0.033 milliseconds which fit into one second (of 1000 milliseconds), i.e. 1000 / 0.033 = 30,000 pulses per second or 30 kHz.

Topic: Magnetic Motors

Question:
If a Flynn Magnet Motor has an even number of magnets and coils on the Stator, how does the motor self start when power is applied, if at all?

Would the assumption be correct that the position of the two magnets on the rotor would be slightly off the exact point of registration of their opposing coils in the direction of rotation, say by 1 or 2 degrees or less perhaps as power is applied to them? The next obvious question would be, how long does the energising pulse have to be? I realise it has to be long enough for the face of the rotating magnet to pass over the Stator magnet. After how many degrees will the rotating magnet be caught in the attraction flux of the next magnet? This period of the coil being energised must obviously be as short and effective as possible, since this will determine the input power.

You state in the literature that the two opposing coils, 180 degrees apart are driven in series. What's the reason for series instead of parallel? If current consumption is the problem, then an adjustment in coil design could easily make a parallel connection draw the same current as a series connection, no?

I know this is not a reasonable question but one I wish to ask anyway. If a motor with the magnets I propose to use, works and works well, using a single platter with the specifications as they are, what could one expect in the way of output power, and what would the total input power be? IF and that is a big IF, this design could attain, even 6000 rpm, it could generate considerable power. If speeds of 20 000 rpm as claimed by Flynn are possible, then I guess even a small motor like this one, could in fact yield a heck of a lot of power !!

Answer:
Self-starting requires a different number of stator magnets or coils to the number of rotor magnets. If the numbers are the same and the stator has separate magnets rather than being one large ring magnet, then the rotor will stop in a position with exact registration of the magnets. So if the build does not allow the user to give it a starting twist, then an odd number of magnets are necessary.

I would suggest that you use an electronic circuit to control the length of the pulse but if that is not convenient, then I would suggest a twin-rotor optical method of adjusting the pulse length as shown for the timing of the Robert Adams motor in Chapter 2. By adjusting to position of the two timing rotor slots relative to each other it allows you to control the unmasked slot length in the timing disc and so adjust the pulse length passed to the optical sensor.

Connecting coils in series or in parallel is just a choice governed by the windings and the user's choice of current, as you point out. The point being made in the text was that being exactly opposite each other, the pulses occur at exactly the same time. However, as you point out, that arrangement would have starting problems.

The torque provided by a single rotor depends directly on the radius of the rotor from the bearing out to the centre of the magnets. Another factor is the pull provided by the permanent magnets. The final factor (ignoring the bearing friction and wind resistance) is the speed of the rotor as the number of drive pulses experienced by the rotor depends directly on the rotational speed. I could see the power output of such a motor as being substantial, even with just one rotor, and by adding additional rotors on a single shaft, the power level should be almost unlimited and I can see no reason why a standard electrical generator could not be driven by such a magnet motor. Remember that only one coil is powered at any one time.

Question:
Here is a question which I hope you can answer. I really have no idea why the coils in the Flynn Magnet Motor drawing have such a large area inside the windings. Obviously the shape of the coil follows the shape of the magnet, but why is the centre cavity so large? If the magnets are circular would there still be a large centre hole? I have noticed this in coils designed for wind generators as well. Your explanation would be appreciated.

Answer:
When a current is passed through a coil of wire the strongest part of the magnetic field which is generated is inside the coil windings. The gap inside the coil windings is the most electronically shielded area when the coil is activated and that is why the gaps inside the coils cover the majority of the stator area. This would be the same if the stator was non-magnetic and had circular magnets mounted on it. In that instance, the gap inside the coil would be the same size and shape as the stator magnet and might well surround it.

Question:

I am interested in experimenting with the Phi transformer. I have been reading your free-energy e-Book for quite some time now. You mention tests with a COP of 8.5 , namely, 140 watts input and 1.2 kilowatt output. Would you assist by pointing me in the right direction in examining studies/literature on the Phi transformer.

Answer:
I'm afraid that I am just passing on the research information which I have come across, and I have not built and tested everything mentioned in the eBook as that would take a great deal of money and probably several lifetimes.

In the case of the Phi transformer, I only came across it twice. Once on a German website where there was a very nice photograph of an exceptionally well-built prototype and once on JL Naudin's website. Unfortunately, I lost track of the German site and did not take a copy of that nice photograph. I think that the performance figures came from that site. I tried e-mailing JL Naudin about the variation shown by him but he never replied, which I gather is not unusual for him.

I am not aware of anywhere else that carries information on the Phi transformer. Two people e-mailed me about their attempts to replicate it using very rough bent steel strips and spinning the rotor with a power drill. Their initial tests appeared to confirm that there was either very little, or no Lenz Law effect. They soon dropped me out of the loop and went on developing while communicating directly with each other. I don't recall ever hearing their final results but have the impression that they did not do very well. However, my impression of the quality of their construction and testing was that it was not great, and with free-energy devices, a high quality of construction can make a major difference.

Having said that, I would suggest that you pick on some other device with which to experiment and I would like to remind you that the eBook is upgraded about seventy times per year on average, so downloading another copy is probably not a bad idea.

One think you might care to consider is adapting a generator to run on water alone as the excess output is in the kilowatts range and not much construction work is needed. Alternatively, if internal combustion does not appeal, then perhaps the RotoVerter which can give a 90% saving in the running costs of electrical equipment.

Hope this helps, and good luck with whatever project you pick,

Question:
I've got this idea for a motor and want your feedback. Say you have a wheel, and around the edge you place magnets having the same poles pointed outward. Maybe 30 magnets and all have their north poles facing outward on this wheel. One magnet is then brought, south end first, at right angles to the magnetic field of one of the magnets. The idea is that this will push the magnet in one direction and force the wheel to move, and because all of the magnets have the same pole exposed, this process of continually interacting magnetic fields should keep on for a while. Very possibly a crackpot idea. I'm getting 40 magnets shortly, each with a pull force of 11 pounds, so I hope they're strong enough to do something.

Answer:
It is very difficult indeed to get a permanent-magnet-only motor going and the setup which you appear to suggest is one which is commonly tried by almost everyone. It generally doesn't work because while there is a repulsion on one magnet which drives the wheel around, as soon as the next magnet on the rotor approaches, it encounters a backward push of exactly the same size and that causes the rotor to oscillate and then come to a stop with the magnets at their shortest distance apart. Using electric shielding to block the unwanted retarding action, as in the Adams motor or the Flynn motor, makes a major difference and can produce great results and high rotational speeds. Good luck with your experimenting.

Question:
Regarding the Orbo details in Chapter 1: What Sean at Steorn is saying is that the permeability of the ferrite core decreases as the rotor magnet approaches (I have verified that this assertion is true). When the permeability is at its lowest point, the coil is pulsed with a very small current so that complete saturation occurs. The ensuing small magnetic field then allows the magnet to skate past the ferrite core. Once the magnet no longer influences the core, a large change of inductance occurs in the core, and as Sean states, it leads to an "energy gain". At this point, the flyback voltage can be captured, and indeed, it is greater than the energy it took to energise the coil. The higher the RPM, the more energy can be captured. There are numerous factors involved in all of this, all of which are quite critical in achieving maximum performance -- coil positions, core permeability, speed, etc.

Answer:
Thank you for the detail on the Orbo design. I find it quite hard to get excited about it due to the earlier Adams and Flynn motor designs. I am more than happy that the people in Dublin are genuine as that was my strong impression when I met them on the first day of the failed London demos.

We are only scratching the surface here. I have had person-to-person information on the Adams motor, information which I think has never been made public. Robert Adams was not willing to share his more advanced developments and died before he decided to share his findings. I am informed that he had got a 200 mm diameter rotor motor/generator up to megawatt level output, which is pretty spectacular. I wonder if we will ever replicate that performance.

I understand that Chas Campbell in Australia reached COP=10 before moving on to a more advanced design which he says has unlimited energy output. He says:

"**How 2 Fix**

To create a power source by using Gravity you must have a constant source of momentum and it doesn't have to be perpetual motion, My system uses an electric motor to generate centrifugal force this is achieved with flywheels. A balanced flywheel attached to an electric motor will actual reduce the power consumption of the electric motor while generating Torque, and you use that extra power to drive another flywheel and so on. Remember, to produce electricity you only have to spin a alternator at its designed speed once that speed is reached you use the torque (hp) to keep it spinning - sounds too easy doesn't it? I can spin a flywheel which weighs 80 kg, at 1,000 rpm and the power consumption of the 750 watt motor is less than it takes to spin the motor when it is attached to nothing.

As a matter of interest, the flywheel has a diameter of 600 mm. Imagine a steel wheel weighing 80 Kg travelling at 113 kilometres per hour. So the next time your electricity bill arrives, ask yourself "why does it cost so much when it can be produced by Free wind, Free sun, Free tides, Free water and Free Gravity which can be produced on site?" No more power lines or high insurance cover needed on your solar panels or wind towers.

Gravity is available everywhere even to the 2+ billion people who live without electricity. I am not smart enough to write a book or design a computer game so I decided to invent something that would make me rich it's been a lot of fun and very frustrating as everybody keeps saying "it can't be done". I am now 73, live in a unit, have a foreign landlord and have spent all my money on my invention. It's time that I told the world how to build the "Safe, Affordable, Helpful, & Clean" generator.

Sir/Madam if you, your company, or your Government would like to be associated with something that will make the world a better, safer place please contact me. I've had a film made that I'm sure you will find very interesting.

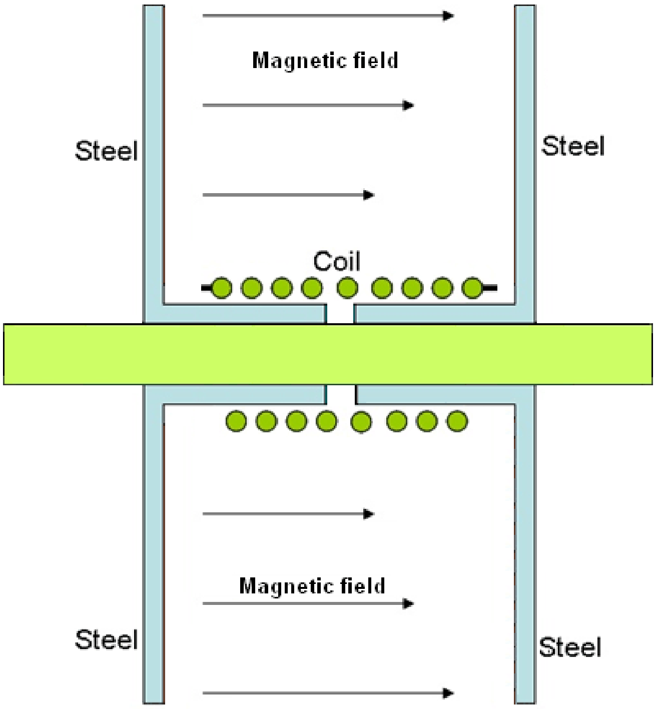
If you send your POSTAL ADDRESS with a small amount to cover my costs to my POSTAL ADDRESS, then a copy of the film in DVD mode will be posted to you.

Sincerely,
Chas Campbell
PO BOX 137, Sunnybank, Queensland, Australia 4109."

It looks like Chas has hit the same brick wall of "zero funds" that most other inventors have. He also seems to have been bitten by the "hey, this design is worth a lot of money, so I could get rich here if I play my cards right" bug. If he manages to make big money, then he will be the first inventor to ever do it.

Question:
How can I block the magnetism between two strong magnets for my new magnet motor design? I am using five layers of mu-metal at the moment but I need a complete magnetic block.

Answer:
Your question suggests that you do not fully understand the nature of magnetism, which is not too surprising as it is not really well taught anywhere at the present time.



If you place two circular steel flanges on a plastic shaft, wind a coil on the plastic shaft and power the coil. the resulting magnetic field is strongest between the outer edges of the flanges and weakest at the coil of wire. Unexpected, but true. The reason is that magnetic "lines of force" (for want of a better term) spread out along the paths of least resistance and the flow divides up in direct proportion to the resistance of the paths. Steel has 1000 times the magnetic conductivity when compared to air, so for every 1 unit flowing through the air, 1000 units will flow through the steel if it provides an alternative path. As the flange diameter increases, so does the area of steel in the flange and hence the magnetic conductivity. The result is that the strongest magnetic field between the flanges is at the outer edge as can be seen from the attached diagram. There IS additional magnetic flow (not shown on the diagram) through the air outside the flanges, but it is very small compared to the flow directly between the flanges.

The bottom line is that it is not possible to **block** magnetic flow with a shield (and mu-metal is one of the very best materials for attempting that). The most you can do is to provide a more attractive flow path for the "lines" of magnetic force, and so persuade them to divert to another direction - they never just stop at a barrier.

So, for your problem, I would suggest just two ways of dealing with it:

1. Use an identical magnet as the "shield" but reversed so that the field oppose each other. That will work, but if your design requires the shield to be moved into position, then there will be a very marked overhead of the force needed to move the magnet against the existing magnetic fields.

2. You oppose the magnetic flow with a magnetic field from a coil, the field only being present when the coil is being powered. That is very effective and the motor power is very much greater than the mechanical power which could be generated from that same electric current. That arrangement is called a Flynn Motor and it works very well indeed.

One other option which does not match your query, is to physically move one of the two magnets relative to the other as is done in the Steven Kundel magnet motor.

Good luck with your project,

Topic: Don Smith's Devices

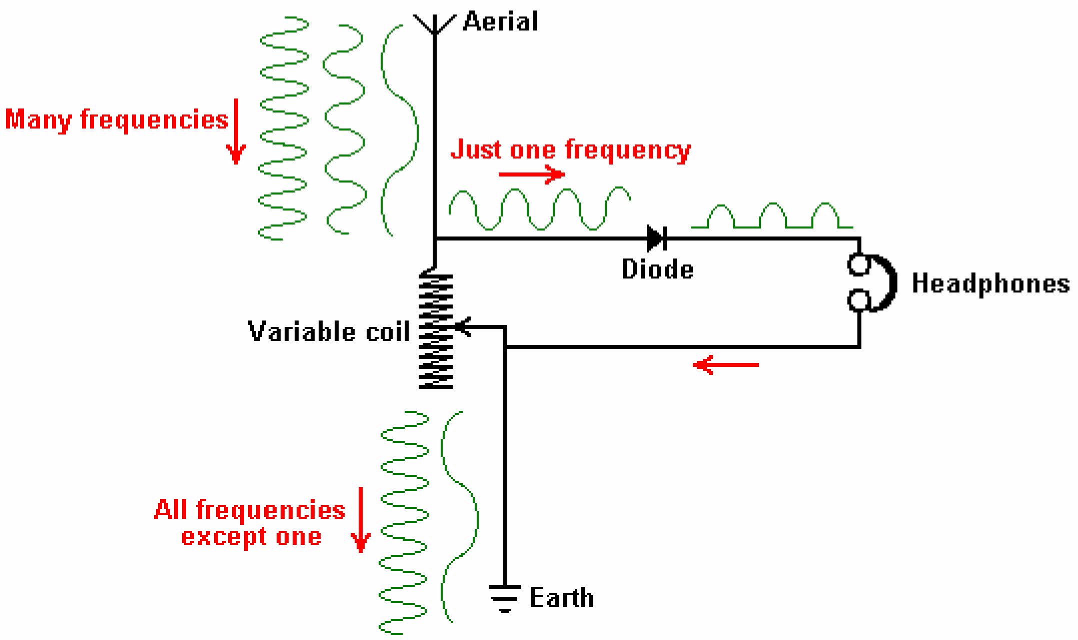
Question:
I am a bit confused though by the frequency conversions necessary to find the proper length of coil for an L1 coil. On page 338 of PJLBook.pdf it says...

Point 1, section d "If using one quarter wavelength, then divide 247 by the frequency in MHz."

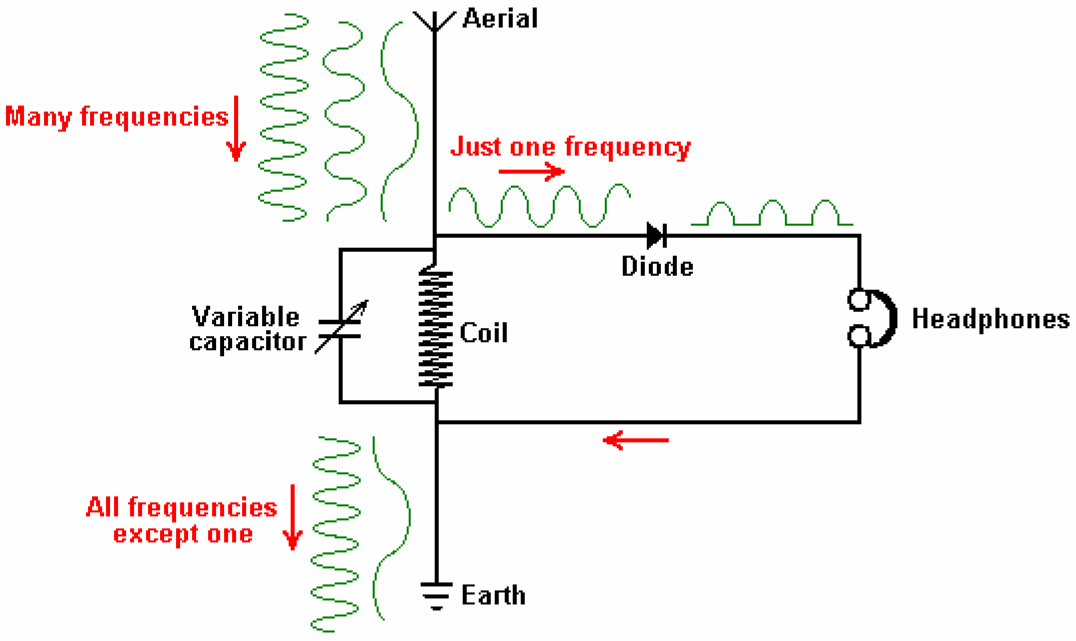
My frequency reads 35.4 KHz or 35400 Hz. That calculates out to .035400 MHz. If I divide 247 by .035400 I get 6,977.40112994 feet. In reading the examples given in Dons pictures and text no reference is given to use of anywhere near that length of wire. In fact the reference to length is in the ten foot range. Am I way off base here or what? Do you come up with the same figures? I have to be missing something, can you help me see it?

Answer:
You are not the first person to ask me that question. It needs to be understood that you are quoting Don Smith and not myself. You should also understand that Don Smith does not reveal everything about any of his designs and I, personally, do not by any means understand all that he says. The Don Smith devices are some of the most difficult to understand and replicate. Don uses various techniques with his different designs although most of those techniques appear to have a common background strategy for energy extraction from what he describes as "the ambient background" and others call "the local environment".

Don goes into the overall principle for estimating the resonant frequency of a coil, where a factor of 247 comes into play. However, a coil and capacitor combination resonate at a different frequency set by their combined characteristics. This is clearly seen in a "crystal set" radio receiver. These very simple receivers can be tuned to a radio station by adjusting the number of turns on a coil. The coil is generally built like a rheostat with a slider connecting to each coil wind in turn.



The tuning relies on the fact that a coil of any particular characteristics such as length, diameter, core material, turn spacing, etc., has one frequency at which it has a very high resistance to AC current flow through it. While we don't tend to think of it as such, a radio signal coming down an aerial wire heading for an earth connection, is actually an AC signal causing an AC current in the aerial and earth connections (and consequently, the coil connected between them). If there happens to be a radio signal which is at that exact frequency, then it finds it very hard to get through the coil and tries to find an easier way past the blockage. The radio builder provides that easier path by connecting a germanium diode and a pair of headphones across the coil. Only that one radio signal takes a detour through the headphones and so the listener only hears one radio station out of the many coming down his aerial.



An alternative construction is where the set is tuned by adjusting the setting of a variable capacitor connected across the coil which has a fixed number of turns. This adjustment causes the coil/capacitor combination resonate at different frequencies, the frequencies of interest are those used by different radio transmitters. The average person thinks of this as "tuning the radio in" to different radio stations, but the reality is that the user is altering the resonant frequency of a coil/capacitor pair. The higher the required frequency, the smaller the capacitor needed.

If a coil has its turns spaced out like the Barker & Williamson coils which Don uses, the coil's inherent self-capacitance is increased dramatically. Dealing with coils energised at high frequencies is a fairly tricky area as there is stray capacitance through the air between components on a board, and so, the physical layout of the circuit becomes a factor in the design and in some instances, placing your hand near the tuning components can alter the stray capacitance of the tuning system.

Don admits freely that he does not reveal all of the details about any of his designs, but he does share enough for enthusiasts to have a reasonable chance of working out the missing details for themselves. To help with this, he explains a couple of his easiest designs in fair detail. The neon tube driver design is one of these. Here, the frequency of the commercial driver circuit is imposed on the small "L1" primary coil winding. If it is not the natural resonant frequency of the coil, then circuit forces the frequency on the coil by pulsing it at that frequency.

However, one thing which Don does not mention is the fact that the current which will flow through that "L1" coil depends on the applied voltage (which is very high and might be 6,000 volts) and on the coil's impedance at that frequency. The practical details of this radio-frequency work is something about which I am almost 100% ignorant, so you would need to read up on the subject or consult an experienced radio-frequency expert.

In the design which Don shows most frequently, he indicates that the performance of the first part of the circuit is governed by the resonant match between the L1 and L2 windings of the Tesla Coil which he uses to step up the voltage to a high level. To make these two coils resonate in step with each other, the L1 coil needs to be made from wire which is exactly one quarter of the length of the wire in the L2 coil. If the coils were the same diameter, that would give a 1:4 step up in voltage, but as the L1 coil has a larger diameter, the wire length makes fewer turns than one quarter of the number of turns in the L2 coil. Consequently, the step-up ratio is more than 1:4 and more than four time the voltage is generated in the L2 coil.

Don implies that if the coil winding is not absolutely exact, you might need a very small capacitor across the L2 coil in order to make the two coils resonate at the same frequency. If this were the only requirement then you would expect to see one capacitor across the "L2" coil to make the matching perfect. However, you will notice that Don uses a capacitor across **both** of the coils. So, why does he need two? This may be my ignorance showing here, but I would suggest that the capacitor across the "L1" coil has nothing directly to do with the "L2" coil at all but is there to tune the "L1" coil exactly to the output frequency of the neon-tube driver circuit, presenting it with a high impedance at the working frequency and so it will draw very little current from the driver circuit.

The frequency in L2 will always be the same as that in L1 which is driving it, but the energy performance is massively better if the L2 coil is operating at its own natural resonant frequency. This may well be achieved by the wire length ratio between L1 and L2 but as the L1 natural frequency has been manipulated slightly by putting a small capacitor across it, I suggest that the capacitor across the L2 coil is to match the capacitor-induced shift in resonance of L1.

In versions of this design, Don converts the AC coming out of L2 to DC with a high-voltage four-diode rectifier bridge and then feeds the power into a large high-voltage capacitor before stepping the voltage down and the current up, with an "isolation" output transformer.
I have seen it said by several different people that a capacitor used like this causes a change in the nature of the incoming energy, making it much more like conventional electricity.

It seems highly likely that what Dons says has a typing error and the "MHz" should read "kHz" and the wire length at your 35.4 kHz would then be 6.9774 feet (not including the straight connecting wires) or 6 feet, 11 inches, and 23 thirty-seconds or 2127 mm. Wound on a 3" former with wire of 0.25" diameter, that would be about 8.22 turns which does not seem unrealistic.

However, bottom line, you have to consider me to be a source of unreliable information here as you are asking me to interpret what Don means and there are probably not many people who can do that and I am definitely not one of them and so have to resort to guesswork here.

With regards to the Ecklin-Brown style motor-driven rotor device, I would suggest that although he does not show it or mention it, that Don tunes the power pick-up coils to the resonant frequency of the pulsing produced by the rotor arms passing by the magnet pairs. Remember that the title of Don's document is "Resonant" Energy Methods and he shows the Ecklin-Brown style device in that document.

Question:
Just to let you know I was at first impressed with Don Smith's research. Having checked other comments about him I now have my doubts. The question is: why did he not commercialise his Tesla system which is described in sufficient detail in your eBook? One of the sites I found did not have good things to say about him. Who does one believe. I sent him an e-mail recently and it just bounced back. It seems that Don has gone quiet.

Answer:
Don Smith is very elderly at this point in time and he has suffered several severe strokes. It is almost certain that he is in no fit state to respond to e-mails. There is a web site set up by his son who gives every appearance of not understanding anything much about his dad's technology.

Don methods are some of the most difficult to replicate as he freely admits that he withholds some vital information because he exploits his designs financially and so Non Disclosure Agreements get in the way. In his various video lectures he remarks that it is not in his financial interests to disclose all of the details but he says that he discloses enough to allow an experienced developer deduce the missing parts and fill in the gaps for himself.

Probably a key point is having the "L1" / capacitor combination reflect a high impedance at the frequency of the driving circuit (probably a neon tube driver). With a high impedance, there is little current draw. Another feature is the need to feed the energy into a capacitor before attempting to use it for "useful work" as the nature of the energy changes in the capacitor and aligns it to our everyday power supplies. The radio frequency experts have a head start in understanding Don's designs as they are nearly all based on high frequency and, for example, RF experts know that metal can be used to insulate between two wires if the spacers are the correct length for the frequency used.

Although Don does not say it, it is probable that his Ecklin-Brown style device has the output coils tuned to the frequency produced by the spinning rotor arms. Also, it is likely that he is using wire with a very large number of fine strands inside it and that seems to have quite an effect on the output.

Question:
I took off from the internet PJK book. I am interested in the device by Don Smith. Unfortunately, since my English is bad, and his logic is a bit different than my Croatian language, I have problems with understanding. The problem is on page 223, chapter 3-37. So I do not understand why I have to divide some numbers with frequency in order to get the length of the wire. For example, if I want to get the wire length in meters for one-quarter the length of the coil, why do I have to divide the number of 75.29 with the desired frequency. What does that number - 75.29? Also I am interested in one quarter wavelength? What do you mean by the term wavelength? Also, do you think that the term quarter means the length of the wire or it means the length of the coil? I counted the

number of turns in the coil of Don and concluded that the coil L1 is a 1 / 4 of 1 / 2 of the coil L2. Can you help me, please, to understand it.

Answer:
Your question is not easy to answer, but I will try to answer it.

If you hit a church bell with a hammer, the bell will vibrate and produce a musical note which depends on the size of the bell. That bell always produces the same note when it is struck.

The bell produces a waveform in the air very much like the electronic waveform produced by most electronic devices.

The note (or "pitch") produced by the bell has a 'wavelength' which is determined by how many times it vibrates in one second and how fast the signal moves away from the bell during that second. The "wavelength" is the distance travelled by the sound during the length of time which it takes for a single vibration.

In electronics, a coil of wire has a resonant frequency, just like the bell has. At that frequency, the coil will vibrate with the minimum amount of input energy possible.

The wavelength of the resonant frequency of the coil is the distance which the electronic signal travels in the length of time needed for just one cycle of it's vibration. Electronic signals generally travel at what is called 'the speed of light' and believed to be about 299,792,458 metres per second. If the coil is vibrating 30,000 times per second (30kHz), then the wavelength will be about 299,792,458 / 30,000 metres or about 9993 metres.

As far as I know, the number quoted by Don Smith is a fixed relationship between the length of wire in a coil and the wavelength of the coil at it's resonant frequency. I am not expert in radio frequency technology, so my explanation of that number may not be fully correct.

A very good resonant ratio between the primary coil ("L1") and the secondary coil ("L2") of a Tesla Coil is 1:4 which means that the length of wire in the secondary coil should be exactly four times the length of wire in the primary coil. That automatically gives the quarter wavelength ratio without you needing to know what the actual wavelength is.

In Don's case, he takes the frequency generated by his neon-tube driver module, and uses the number which you are asking about, to calculate the length of wire in a primary coil which will require the lowest possible amount of current to make it vibrate. That is, the coil's resonant frequency of vibration will match the neon-tube driver module frequency exactly. Other wire lengths will work, but the very best length is the one which he calculates. I hope this helps in spite of the language difficulty.

Question:
in Don’s air core coil builders guide he says for L2 wire length at 1/4 wave - divide 247 by frequency. in his example it works out nicely at 10ft. My transformer is from 30 to 40kHz. lets say 35kHz to be in the middle. 35kHz = 0.035MHz (I think). so 247 divided by 0.035= 7057 ft! Now that’s a wee tad on the long side me thinks! So I’m guessing that I can keep dividing until I reach a realistic coil length? Here’s the question, for L2 to be in harmony with the 35kHz transformer output should I keep dividing the 7057 by even numbers OR by 247, or am I barking up the wrong tree completely?

Answer:
I don't claim to be any kind of expert on this stuff, but this is what I understand:

The heart of a Don Smith design is a resonant transformer. That transformer runs at high frequency and so it needs to be air-core. It can be either step-up or step-down. The lower voltage side needs wire of twice the thickness of the high voltage side. It is this transformer which is the ONLY part of the design which must be resonant and the resonance is between the two windings of that transformer, because at resonance (and not at ANY other frequency) the secondary becomes a room-temperature superconductor with no resistance at all.

To get that exact resonant match, either the length of wire in the turns of the thick-wire coil has a length which is exactly one quarter of the length of wire in the turns of the thin-wire coil OR alternatively, either or both of those coils has a capacitor placed across it so that the coil/capacitor combination has exactly the same resonant frequency of the other coil (or coil/capacitor pair if the other coil also has a capacitor wired across it).

If the two sides of that transformer are matched for resonance, then it doesn't matter what frequency is fed to the primary as the secondary will resonate with it. It is like striking a bell with a hammer. The bell has a specific resonant frequency and it will resonate at that frequency no matter how fast or how slowly it is hit with a hammer.

So, if you let your high-frequency power supply fill up a small high-voltage capacitor to some high voltage until it discharges suddenly through a spark gap (or neon or gas-filled discharge tube) and through the primary, that sudden voltage spike will generate a massive output in the superconducting secondary winding, even though the frequency of the sparks is not the resonant frequency of the primary coil.

The main problem is now encountered and that is the fact that the voltage and current in the secondary coil are ninety degrees out of phase. That means that when the voltage is high, the current is very low and when the current is very high, the voltage is very low, and so the output power appears to be very low even though it has the potential of massive output power. As I understand it, one way to overcome this is to wind the second half of the output coil in the opposite direction to the turns in the first half of the coil. That is, if the first half has clockwise turns, then the second half has counter-clockwise turns. The two ends are then joined together either with a high-voltage diode on both ends or without any diode. The output is then between the centre of the two-section coil and the two combined ends. This joining of the ends of the coil, combines the current and voltage outputs and that composite signal is then ready to drive the primary of an air-core step-down transformer to give lower voltage at higher current, ready to be rectified to DC or to have it's frequency altered by pulsing the output at the local mains frequency.

Chapter 3 has an attempt to explain this in fair detail, starting at page 46. Some people are of the opinion that the grounding wire and/or the connection to the load will alter the frequency of the secondary coil. I have no idea if that is so or not and experimentation is needed to check it out.

Good luck with your project

Topic: General Items

Question:

I was doing a web search today and came across your comprehensive book on free-energy devices. Since I've recently been introduced to this concept of the Zero-Point Energy Field, and still remain sceptical of a true Over Unity machine... I would like to ask if you have seen any such models working in person, with your own eyes? Something that runs without external energy input for an extended period of time!

If I were to replicated some of the experiments, is it easy to get in contact with those inventors? Have you been able to contact them and have had fruitful communications in the past? My curiosity is high, and I would highly appreciate your assistance!

Answer:

Thank you for your e-mail. I fully understand your caution in accepting something which you can't see and about which conventional science appears to be doubtful - calling it "dark energy".

I have met with just a very few of the people mentioned in the eBook as the internet allows us to talk freely to anyone around the world while getting together is usually VERY expensive and often almost impossible. I have met with Bob Boyce and Ed Holdgate in the USA and Dave Lawton who is in Wales. I have corresponded with many people around the world, including John Bedini, Tom Bearden, Ravi Ravu, Lawrence Tseung, Scott Cramton, Tom Thayer, Ron Pugh, Bill Williams, Lawrence Rayburn and a host of other people who have achieved COP>1.

Because of the fact that people are so scattered around the world, I have only seen "with my own eyes" two COP>1 electrolysis systems and one battery-charging COP>1 system. After much correspondence, I have not the slightest doubt as to the complete honesty of many of the people claiming to have working devices, many of whom do not want their names published and several who do not want any details of what they have achieved, disclosed in any way.

Many people think that those who claim these things are just seeking publicity while the reality is just the reverse with most wanting to be left in peace and many quite reluctant to share the details of what they have achieved. One of my biggest problems is that most inventors are driven by curiosity and when they succeed, they lose interest and move on to something else about which they are curious, usually taking the successful device apart in order to use the components for something else, and never documenting what they did.

Dave Lawton's successful replication of Stan Meyer's "Water Fuel Cell" had reached his spares box for recycling when he happened to mention it to me when talking on the phone. I then persuaded him to let me document it, and dozens of people have, since then, made successful copies of Dave's cell. Dr Scott Cramton worked on from that document and has reached 6 litres per minute of hydroxy gas for about 36 watts of input power (which Faraday would have believed to be impossible, stating the maximum possible performance would be 842.4 watts to get 6 litres per minute).

There is no way that I could convince you of the reality of the energy field, although I might be able to persuade you on devices which have a greater output than your input (your refrigerator for example which is COP=3).

Question:
I was looking through the "bedini_monopole3" Yahoo forum files for performances achieved, and most people have reported COP results of between 0.85 and 1.2 with a couple of wild results. Is this all you can get from a Simple Schoolgirl battery pulser?

If the recapture of Back EMF is central to COP success, then should we simply set up a coil, pulse it with DC, capture the Back EMF, making sure that the pulsing frequency is low enough to allow the coil to charge up? It seems too easy and too straightforward.

Answer:
The Ron Pugh Bedini pulser shown with photographs in the eBook has run at COP=11 with a bank being charged from a single battery. Few people construct to that quality or tune accurately like they should. Batteries are not a great solution and a generator running on water has massively greater use to a person - you won't get any battery pulser gaining more than 4 kilowatts.

Picking up Back EMF can be relatively straightforward. Remember the man in South Africa who charges up his 10 Amp-Hour battery each night using the battery which is being charged to power the circuit which is doing the recharging. That system uses Bob Boyce's toroid plus three diodes and one small toroidal choke. At the present time, that circuit recharges at just 12 watts (i.e. 1 amp of current) which is not a massive rate of recharging, but the overall performance is spectacular as present-day science says that doing this is "impossible" and yet this man has done it more than 35 times in a row.

I have a problem with batteries. To get the sort of current supply which a household needs, an impossible number of large, expensive batteries are needed. Even if you keep the rate of discharge down to discharging over the recommended twenty hour period, those batteries will need to be replaced on a regular basis. Also, batteries are not 100% efficient and so part of the current which you feed into them will not be returned to you when you need it to power your equipment. What is really needed is some alternative system which can generate the needed power at the time when you need it. For that reason, while I am not a fan of internal combustion engines, a generator which has been adapted to run off water alone and which provides several kilowatts of excess power, looks like a much more viable solution to off-the-grid power.

Question:
I would welcome your comments re certain passages in Chapter 5. It talks about the load being powered indefinitely. However there are certain references to discharged batteries being restored under a minute and also that the batteries would charge up to nearly 36 volts with no apparent ill effects. After the discharged battery is restored after a minute this would seem to indicate that after one minute all batteries would start being overcharged. Does this matter? Is there any danger of damage, fire or explosion? There was some mention of control circuitry to prevent over-charging. If the circuit behaved itself during trials why would control circuitry be needed? Also, would not this compromise the correct working of this system? At the moment I am only thinking of using rechargeable batteries.

Answer:
Rechargeable batteries should be ok. John Bedini's "cigar-box" demo Tesla Switch used rechargeable and it ran for six months solid until it was smashed by the opposition who then intimidated John. The section in Chapter 5 which you mention is a quotation of what the Electrodyne Corp. people reported as their experiences with their implementation of the Tesla Switch. They were using four ordinary car batteries. I don't think that lead-acid batteries have any problem with over-voltage when they have become conditioned through Tesla Switch use for a month or two. The over-voltage protection was a suggestion from me and I believe that any problems which they had with the higher voltage were most likely to do with the voltage rating of the components in their circuit rather than with the batteries themselves.

Please be aware that the Tesla Switch pulser physical layout on stripboard shown in that chapter was corrected for an error very recently and so you should download a new copy of chapter 5 (or the eBook) if you intend to build from that particular layout.

Question:
I may have missed any discussion in regards to patents, so I would like to know if these are public domain, or what, if any, restrictions are involved in making one for oneself, or selling plans, or products.

Also, do you have a recommended parts warehouse? I am in the midst of searching, and would like to buy capacitors, chokes, and diodes from the one place. Any help you can give along these lines would be appreciated.

Answer:
Patents are documents of Public Record and so may be reproduced by anybody for any purpose. You are able to make anything shown in a patent for your own use. A patent has extremely limited power and is only there as a low-grade tool against competing commercial companies trying to outsell the patent holder. They can be used by rich and powerful individuals to harass and oppose the individual inventor or very small business by wasting a massive amount of time in court - time which should have been spent in production, and wasting vast amounts of money in defending against court cases (which may well be frivolous). Even if you personally, hold a patent on some device, you would need a tremendous amount of money to fight a patent application from someone else, even though the new application is clearly based on your design. Patents are only useful for very rich people.

There are links to electronics outlets on my websites, but you don't say what country you are in. In the USA, mouser.com might be a good source, while in the UK, perhaps ESR, Maplins or RadioSpares might be your choice.

Question:
May I ask what excess energy devices are there which have no moving parts?

Answer:
There are many devices of that type, with Don Smith having about four dozen, Herman Plauson describing aerial systems of his as being "small" if their output is not over 100 kilowatts, Bob Boyce's toroid which self-charges batteries, Steven Mark's toroid, the Colman/Seddon-Gillespie 1 kW battery, and many, many more.

Mind you, the ones with no moving parts are more difficult to get working as they usually need tuning and most people don't have the necessary level of patience (and many don't have the know-how either).

Question:
It appears resonance is the key to success. Although I have a background as an electronic technician, I am a complete novice regarding "free energy". I have been reading everything I can get my hands on. If you have any other informative references please let me know.

Answer:
The problem with the information is that different people have different theories on what happens and how it happens in the free-energy arena. Some people believe that it is electron spin while others believe that it is the ambient background being nudged into imbalance and others believe that the interface is through rotating magnetic fields.

It is distinctly possible that each of these views is correct and that there are several ways of tapping this energy. However, I can't point you at any one definitive text which describes it all in detail and explains how to gather and use it easily and cheaply.

We have been held back to the 1903 level of flight where flying is just not available to almost anyone. For us now, free-energy is just not available to almost anyone. Worse still, the internet is being smothered with legislation to curtail its use. Unelected people can dictate that any site is excluded from people in their country. The countries which have already implemented this are China, Australia and the UK and I think that the US is likely to do the same in the near future. I would expect my website to be in the list of excluded sites.

So, to answer your question, if I knew of any really good material on the subject, I would either have it on my web site or I would point to it. So sorry, nothing additional springs to mind.

Question:
I recently read with interest what you had to say about colloidal silver, but have I think found a problem! You state that in order to produce colloidal silver that it is necessary to use distilled water and that the silver rods are

placed on opposite sides of the beaker. Well even at 27 Volts it is impossible to produce Colloidal Silver in distilled water with a electrode spacing of say 6.5 cm. So I ask, is distilled water really used or if it is anything else added?

Answer:
Highly distilled water is indeed used, and if you don't stir it, you can see streamers moving across between the electrodes. I have found the resulting colloidal silver to be very effective. Ravi in India uses the 200 cc container as he treats many people. I use a much smaller "snifter" glass whose internal dimensions are 40 mm tapering to 28 mm over a depth of 45 mm. This is because I generally use a nebuliser (or apply it externally which is really excellent for skin damage) and the dose volume needed is then very small, perhaps 8 cc or so.

I generally prepare the liquid for about 15 minutes and clean the silver oxide off the negative electrode twice in that period as it builds up very fast. The positive electrode goes non-reflective grey. I could only get much smaller diameter silver wire and so I use about eight strands on each side, bent back on itself in a vertical bundle, in order to get greater surface area.

Question:
There are so, so many areas of possible research that the challenge, for me anyway, is just in making the decision on what to try. There are two that I think I'd like to take a stab at:

1. The Tesla Switch.

2. The Stephan Leben circuit (base upon the original of Alexander Meissner).

However, I have a question concerning each of them. For the Tesla Switch, I've read that an electro-mechanical switch is preferred (and maybe necessary for the highest potential for bringing in radiant energy). In searching a switch of this type I could not find much online to help direct me, so can you suggest a possible component here?

For the Leben/Meissner circuit, what would be a likely choice for the transistor? (That is the only component that was not named, of all the parts listed).

I would have preferred to just dig in and try these two on my own, but since my electronics background is practically nil (with the exception of assembling a Xenon strobe light circuit from a kit many years ago) I was hoping you might take some pity on this poor physics-challenged soul and offer a couple of pointers. Any information you may provide in this regard will be most appreciated. Thank you, in advance.

Answer:
Thank you for your e-mail. Chapter 12 is supposed to give you enough electronics background to allow you to understand and build circuits of this kind. If it has not done that for you, then please give me a steer as to what more is needed and I will expand the chapter accordingly. (This is a genuine request on my part and is not meant to have any kind of negative connotations.)

The phrase electro-mechanical switch does not ring an immediate bell with me but the term implies that it is a mechanical switch which is activated electrically. That would include relays and the mechanical motor-driven switch shown as being what the Electrodyne Corp. staff used (it seems likely that Don Kelly was one of those Electrodyne Corp. people). Transistors were used in John Bedini's circuit replication which ran solidly for six months before it was smashed and he was intimidated into silence.

The reason why mechanical switching is sometimes recommended is because many people do not know how to get fast switching with semiconductors. The Tesla Switch circuit needs to have all the components working together and so even the diameter and length of the connecting wires can make a difference. It is a circuit where heavy loads will work better than tiny test loads as cold electricity operates the reverse of hot electricity and so the heavier the load, the better it works. It is one of the most difficult circuits to get working well, so you might be better off picking a different project.

I think that it is unlikely that the transistor in the Leben circuit is at all critical. Technically, it needs to be able to handle the current, and that will depend on the wire size you use and the number of turns (and to a lesser degree, on the frequency which is determined by the size of the capacitor). An MJ11016 is a powerful, high-gain transistor which should work well. A BD243C transistor is popular in circuits of this type although it has a much lower gain. Hope this helps, and good luck with your project(s).

Question:
Always been a fan of yours ever since I built my first "D18" cell which may I add is still going strong and saving me loads of money. I have a question regarding the Tesla Switch: you mention that the contacts on the discs attached to the motor are set at angles. Can you please explain in more detail.

Answer:
You are the first person I have ever come into direct contact with who has ever had any success with the "D18" Nitro Cell and I have had to classify it as a "doubtful" device because of that. If you are getting a benefit from it, then I would be delighted to change it's classification and combine with you to do a better presentation of the cell including your experiences with making and using it - if you have no objection to this, then please get back to me.

I'm sorry that you have found the switching disc details difficult to understand and I will upgrade the description in the next issue of the eBook. What I was trying to say is that each disc has one sixth of it's circumference clad in copper while the following sixth of the circumference is a non-conducting material.

As there are 360 degrees in a complete circle, one sixth of the circle covers an angle of 60 degrees, which is why 60 degrees is mentioned at the present time. I will expand the description to explain this in more detail. There is no question of the actual copper cladding (or whatever method of conducting contact that you choose to use) being itself angled in any way - it is just a case of there being three sections of the disc being conducting and having an equal sized non-conducting section on each side of the conducting sections. as the contact pairs are exactly opposite each other, this causes one pair of contacts to conduct while the pair directly opposite it is not conducting. Hope this helps and my apologies for the poor description in the eBook.

Question:
I was starting to get really interested in this Free Energy stuff, and before I found your website, I had contacted CAT (Centre for Alternative Technology, based in Wales). I presume that you have heard of them?

Anyways, I was hoping to get some information from them regarding the best renewable source of energy (I was thinking of using a small hydro scheme). I thought I'd also ask their advice on Hydroxy production. As I should have expected, they lambasted and patronised my comments so thoroughly I gave up any idea of hydroxy. If an organisation such as CAT finds hydroxy ridiculous, I couldn't believe that there was any future for Hydroxy on demand.

Do you know of anyone that has managed to heat their home using hydroxy? and if so how? Would be interested to hear any ideas.

Answer:
The 'Chapter14.pdf' document shows ways to use hydroxy for heating - which is one of the most difficult things to use it for.

Your problem with 'CAT' is due to your not understanding the overall situation. Please don't for a moment take what I am about to say as being condescending or negative in any way as it most definitely is not intended to be.

There is a foreign State which is not answerable to anyone, based in London but it is not part of England or Britain. They have chosen the deliberately confusing name of "The Crown" (which has nothing to do with any Monarch) or the "Inner City of London". Their objective is to enslave and rob the British population without them ever realising what is happening. They are a consortium of bankers and lawyers and their biggest attack weapon is a society which they set up and own. It is called "The Law Society" and they use it to mount attacks on people who do not understand the situation.

They have set up a large number of commercial companies, each with a name intended to confuse and distract. One of their companies is called "The Ministry of Justice" and the name is intended to give the impression that it has ruling powers, when in fact, it is no different to a company such as Ladbrokes betting shop. Other companies which it owns include every Magistrates Court, every Police Constabulary, every Local Council, "The Bank of England", etc. etc.

They bolster their illusion by having a 'parliament' where their employees appear to argue with each other and people in general are fooled into thinking that those employees are working for them, and every so often, they even get to choose which employees are hired. The reality is that all important decisions are made in accordance with whatever the owners want and those decisions bear no relationship whatsoever to the facts or the benefit of the population as a whole.

Vast amounts of money are stolen on a continuous basis, using names such as "National Debt", "Foreign Aid", "Income Tax", "Council Tax", "Value Added Tax", "Fuel Levy", "TV Licence", etc. etc. etc.

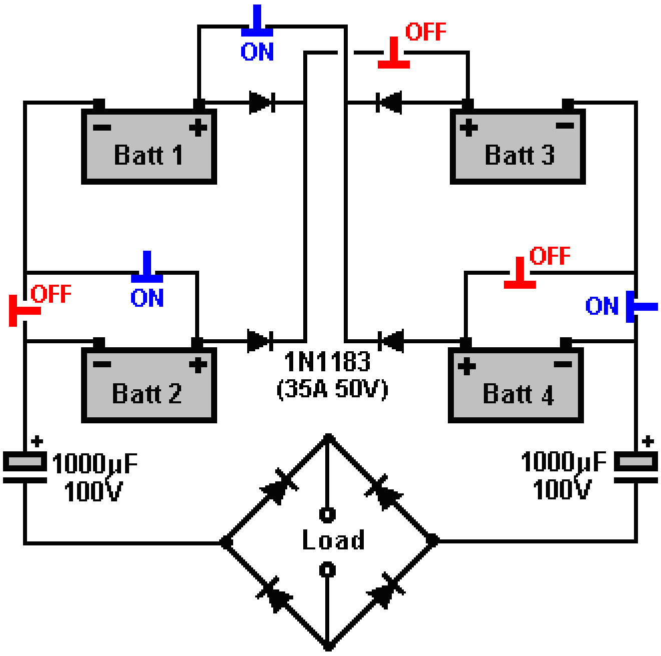
They own agencies such as CAT and under no circumstances would they ever approve the use of any fuel which you do not have to buy from them, so HHO is OUT !! I suspect, although I have no direct evidence for it, that any subsidies offered for "green" projects are arranged to funnel money into the coffers of their friends and colleagues as that would be wholly consistent with everything else that they do. They will only ever support projects which will be ineffective and expensive. Dave Lawton has suffered at their hands when he made a grant application and was then visited by two CIA operatives (and yes, the CIA does operate freely in Britain with the full approval of the government which is owned by the foreign independent State "The Crown").

So, your asking them about HHO was roughly equivalent to asking them if they would mind if you were to stab them with a large knife - not exactly a popular enquiry. They repeatedly undertake false public relations exercises to convince the population that free-energy is 'impossible' and that using an HHO booster on an engine never gives any benefits at all - both of those statements being wholly false.

So, I would suggest that you stay away from CAT and similar companies as they are, in fact, the opposition and most definitely are not there to help you.

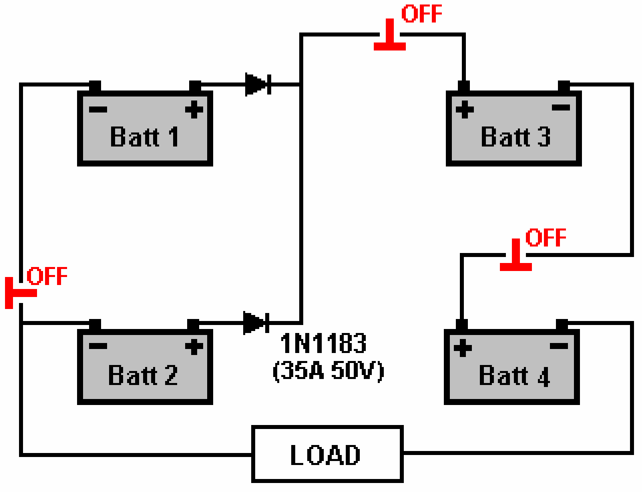
Question:
I have difficulty in understanding how electronic circuitry can be used to drive a Tesla Switch. Would you please show me how the components can be connected together.

Answer:
The Tesla Switch circuit used by the Electrodyne Corp. staff is shown here:

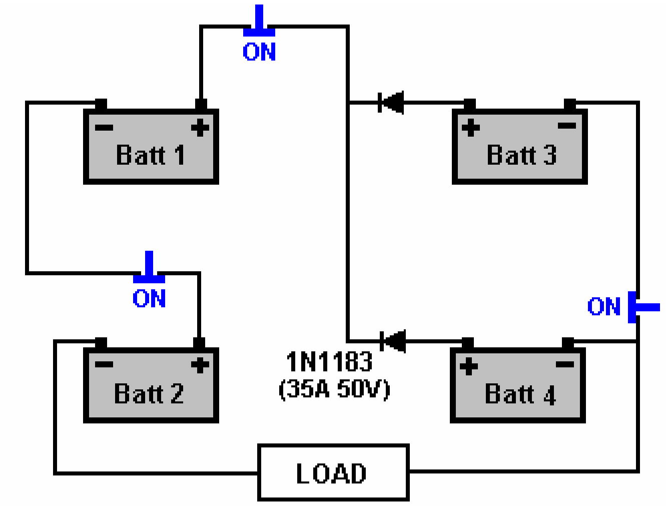


It is distinctly possible that the circuit does not reveal all the information needed for this system, as it may be necessary that the frequency at which the circuit runs needs to be a resonant harmonic of the batteries, or possibly, the load need to be a motor which generates voltage spikes. I do not know if that is the case, but I do know that the 1N1183 diodes are connected in reverse because they break down suddenly, passing a voltage spike to the batteries. It is distinctly possible that the batteries need to be conditioned for this circuit to perform the way that the Electrodyne Corp. staff reported. It should be remembered that they experimented with this and similar circuits for something like three years and it is highly likely that by the time they recorded their spectacular performances, the batteries had been very well conditioned due to the tests which they ran during those three years.

However, if I were to start experimenting with the circuit, I would show the two separate switching arrangements like this:



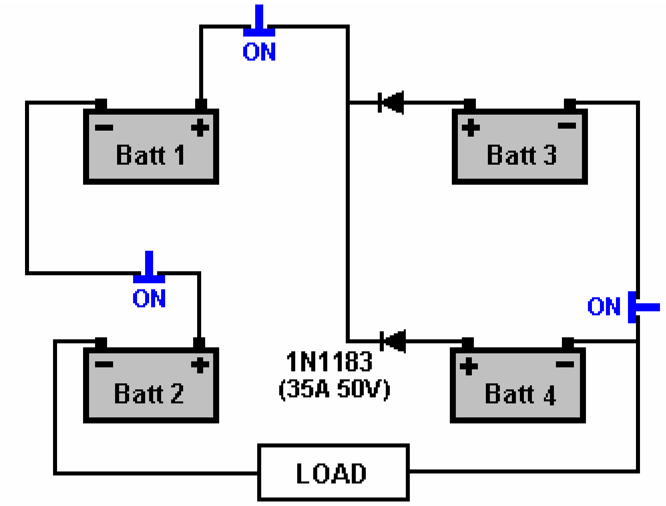
OFF
Batt 1
Batt 3
OFF
OFF
Batt 2
1N1183
(35A 50V)
Batt 4
LOAD



ON
Batt 1
Batt 3
ON
ON
Batt 2
1N1183
(35A 50V)
Batt 4
LOAD

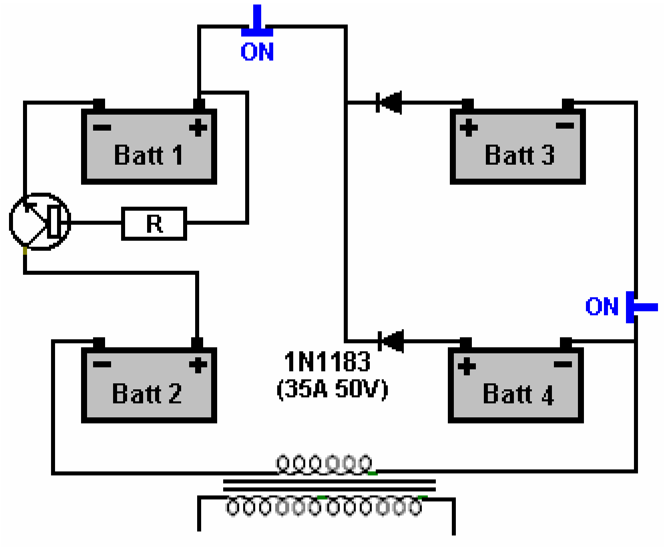
You will notice that each of these circuits are very direct and simple in themselves, but the “LOAD” is an essential part of the circuit and without it being in place (and able to carry current) neither circuit is completed. Personally, I would be inclined to use the 12V winding of a mains transformer as the load connection as that can handle both DC and AC current flow and the mains winding can have a bulb connected to it to show how the circuit is performing.

So, we are faced with two separate sets of three switches where each set needs to be closed when the other set is open. The question is, how can we use transistors to implement those switch operations? The difficulty is that there is no common negative voltage rail as the batteries keep getting swapped over as the circuit operates (which is the whole point of the circuit), and so, ideally, we want to switch each transistor with it connected permanently to just one battery. One circuit is:



ON
Batt 1
Batt 3
ON
ON
Batt 2
1N1183
(35A 50V)
Batt 4
LOAD

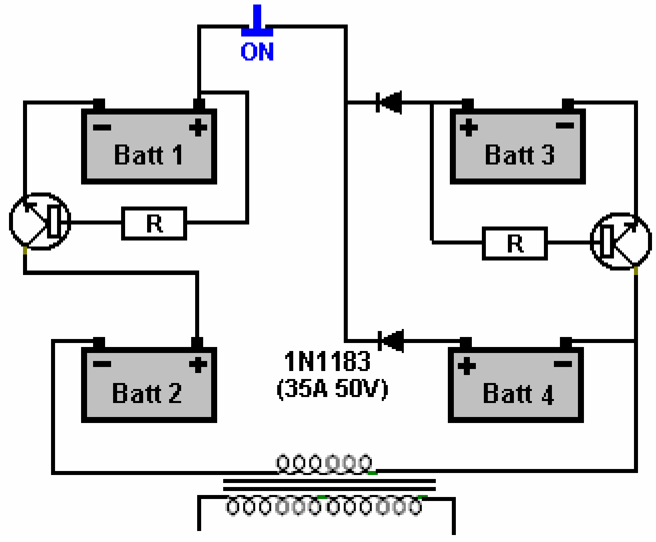
So if we were to use a transistor instead of one of the switches, we might make the circuit this:



ON
Batt 1
Batt 3
R
ON
Batt 2
1N1183
(35A 50V)
Batt 4

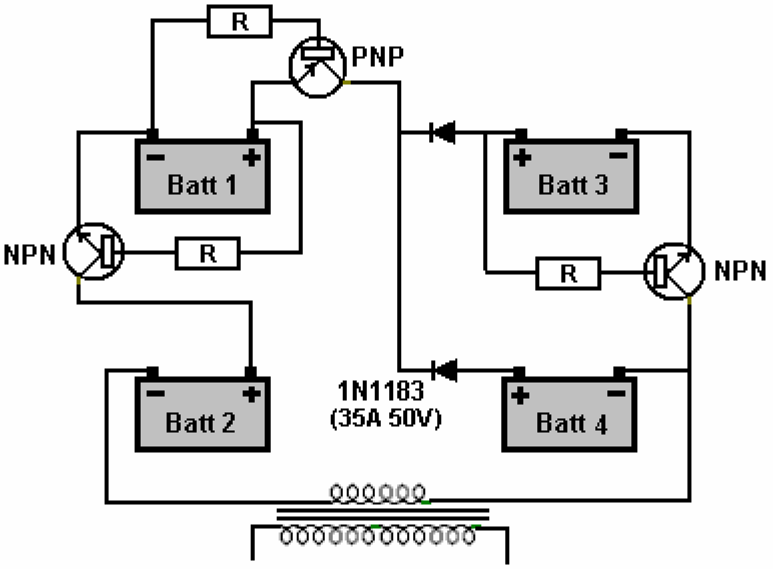
Here, the NPN transistor base is fed a current through resistor R, and as the transistor emitter is connected to the Battery 1 Minus and the resistor is connected to the Battery 1 Plus, there will always be a voltage difference able to feed current to the transistor base, switching it fully On. Obviously, we do not leave the resistor R connected to the Battery 1 Plus all the time, but will introduce some form of solid-state switching to switch the transistor on when we want it to be on and not at other times.

We can swap another of these switches with an NPN transistor like this:



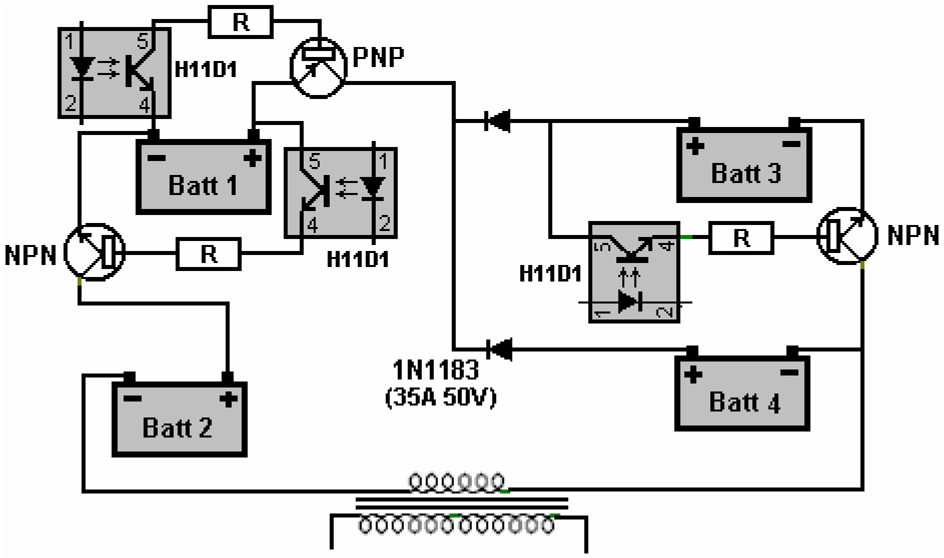
ON
Batt 1
Batt 3
R
R
Batt 2
1N1183
(35A 50V)
Batt 4

But we now get stuck because the remaining switch does not connect to the negative side of a battery. We can get around this by using a PNP transistor as it is the mirror image of an NPN type. The circuit could then be:



R
PNP
Batt 1
Batt 3
NPN
R
R
NPN
Batt 2
1N1183
(35A 50V)
Batt 4

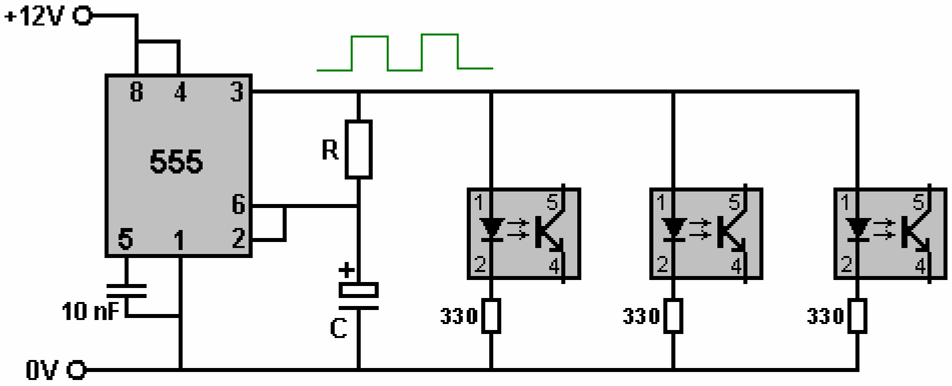
This circuit will have all three transistors switched On as heavily as possible at all times. But while that does appear to substitute transistors for mechanical switches, we want to be able to turn that set of three transistors On and Off when we want. That can be achieved by making the transistor base current flow through an Opto-Isolator which can be controlled by a completely separate circuit which is not connected to this Tesla Switch circuit in any way, perhaps like this:



R
H11D1
PNP
Batt 1
H11D1
Batt 3
NPN
R
R
NPN
H11D1
1N1183
(35A 50V)
Batt 2
Batt 4

The opto-isolators shown here happen to be H11D1 types but many others could be used. Many different components could be used. The resistors 'R' could be, perhaps, 4.7 K, the PNP transistors MJ11015 and the NPNs MJ11016 or any high-gain, high-power transistors.

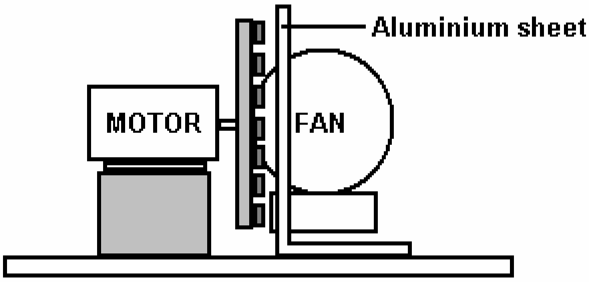
The three opto-isolators can be driven by a 555 timer signal generator which has a 50% Mark/Space ratio, perhaps like this:



The 555 timing resistor 'R' can be replaced with a fixed resistor and a variable resistor in series, so that the frequency of the switching can be adjustable. A rate of 800 Hz might be suited to this circuit. Chapter 12 has a table of the R and C values for different frequencies (perhaps 100nF and a 4.7K plus a 100K variable in this case). The other three opto isolators can be driven via an inverter IC or via a PNP fed by pin 3 of the 555 timer IC. The transistor substitution for switches for the second part of the circuit can be done in the same way.

Question:
In chapter 14 you talk about the Frenette heater, under that article you make the suggestion that one could spin magnets next to an Al plate and make heat. I do not quite understand this, is there any way you could explain a little further, or make some drawing with suggestions?

Answer:
A simple magnetic heater is just a motor with a disc mounted on it's shaft. That rotor disc has magnets mounted on it and an aluminium plates is placed beside it as shown in the diagram below. As the magnet disc spins, it causes rapidly changing magnetic currents in the aluminium which causes it to heat up. If you use an ordinary fan to blow air across the aluminium plate, you get a hot-air heater system. Having sideways "fin" plates on the aluminium sheet should improve the heat transfer to the air.



Question:
What drawing package do you use to produce the diagrams in your eBook?

Answer:
I use the "Paint" program which comes free with Windows. As that answer upsets people, I have produced three casual videos explaining how easy it is to use. As I don't have a video camera or a phone with video facilities, these videos were produced using the FoxMagic program "Screen Virtuoso".

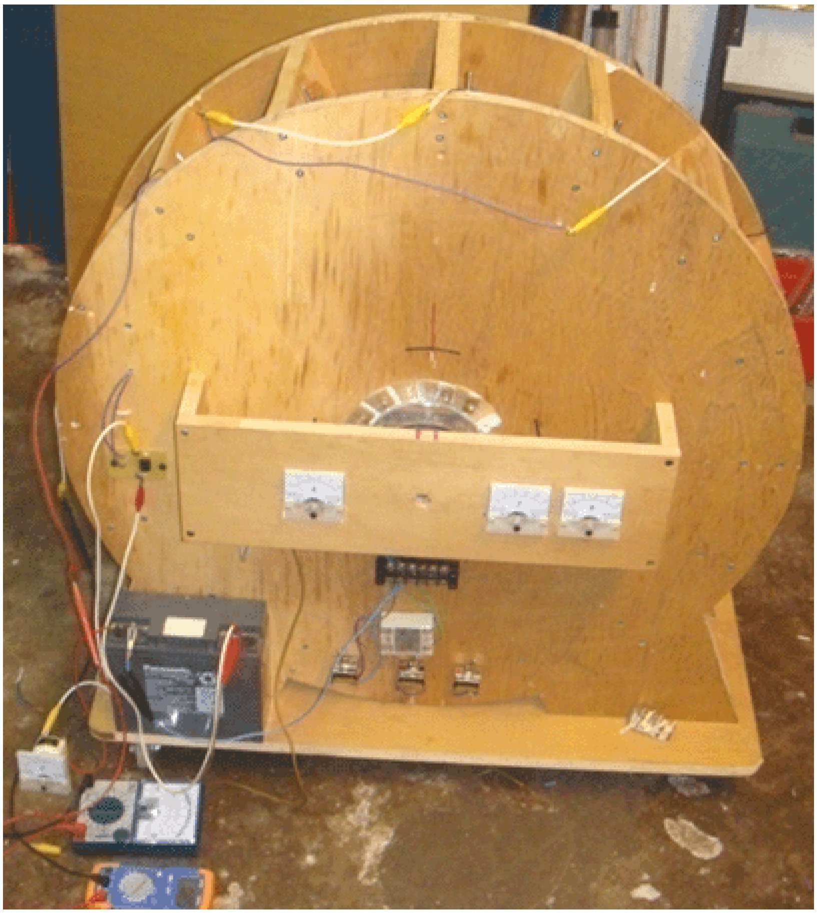
Chapter 17: An Easy-Build Generator.

Many people want a simple project which they can build and which demonstrates free-energy. Let's see if this need can be met. You must understand that most generators, whether free-energy or conventional energy, are not particularly low-cost to make. For example, if you wanted a device which showed that burning a fuel could propel a vehicle, then building a car could do that, but making a car is not necessarily cheap. However, let's see what we can manage here.

However, please understand that you, and you alone, are responsible for whatever you do. This presentation is NOT an encouragement for you to make or build anything. It is merely some suggestions which you might find helpful if you have already decided to build something. This means that if you injure yourself, neither I nor anyone else is liable in any way. For example, if you are cutting a piece of wood with a saw and are very careless and cut yourself, then you, and only you are responsible for that – you should learn to be more careful. If you drop something heavy on your toe, then you, and only you, are responsible for that. Normally, constructions of this type do not result in any kind of injury, but please be careful if you decide to build.

In chapter 2 of the ebook available free from http://www.free-energy-info.tuks.nl there is a rotary generator design by Lawrence Tseung which was built by Mr Tong Po Chi and his colleagues. Being an open and straightforward construction, it has been demonstrate publicly, on many occasions as having 330% efficiency, that is, the output power is 3.3 times greater than the input power. Another way of saying this is to say that it's Coefficient of Performance is 3.3 (or COP=3.3). Hopefully, we will achieve much better performance than that in this construction. No drawings in this document are to scale.

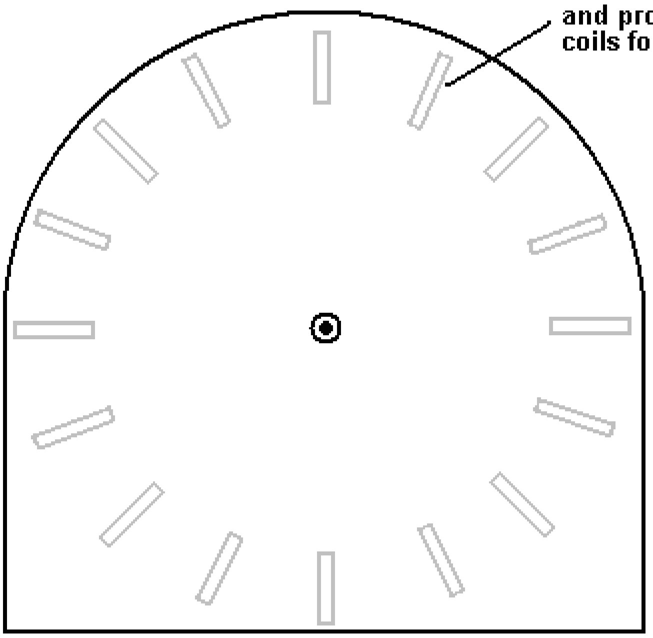
I suggest that we start by replicating the original design, and then apply some modifications step by step in order to raise the output power. The original construction looks like this:



In the version shown above, there are six electrical meters, but those are not necessary and they were included to help when demonstrating the device to members of the public. Built in October 2009, the unit shown has a 600 mm diameter rotor (which is not visible in the photograph). It has 16 permanent magnets mounted on the rotor rim and 16 air-core coils mounted on the stator, one of which is used as a timing sensor. The coils can be switched to act as either rotor powering coils or as power collecting coils.

Initially, power is provided by a small lead-acid battery. The power is applied through the very simple switching style shown in the 1974 patent of Roger Andrews US 3,783,550 where a passing magnet activates the circuit which powers the system. The rotor magnets trigger the operation and the fifteen main coils mounted on the stator can be switched to be either electromagnets pushing the rotor on it's way, or as energy-gathering coils producing a power output.

If you are a skilled constructor of new devices, then please excuse me for making so many constructional suggestions aimed at first-time constructors. The main generator components are like this:



Cross timbers hold the two sides together
and provide mounting points for the 16
coils for each rotor

Stator
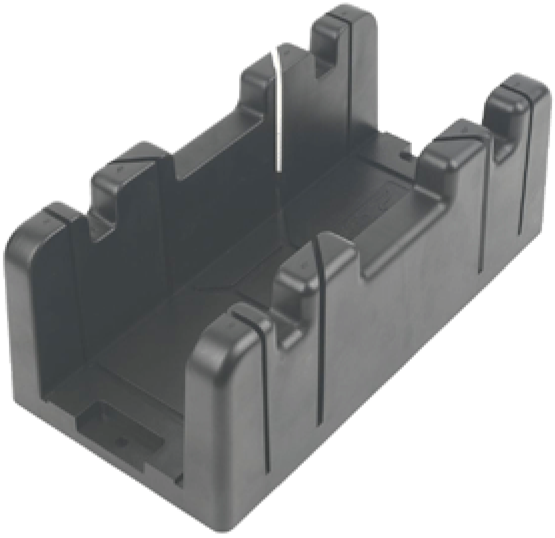
Switch

The wooden planks holding the two sides together, are chosen to be wide enough to give stability, and more importantly, to allow space so that three rotors could be mounted on the axle if using multiple rotors is chosen as one of the various upgrade options. The two stator sides are connected together by sixteen lengths of wooden plank and to a much lesser extent, by the baseboard. The dimensions of all components will be suggested later, but for the time being, let's concentrate on connecting the stator pieces together properly.

Each plank is supplied with a factory cut straight edge top and bottom. The end of the plank supplied has a perfectly square edge, but we have to cut the required length and get a good cut every time. It is easy enough to mark a perfectly square line across the width of the plank, but cutting along that line is not sufficient as the cut needs to be absolutely square as it moves through the thickness of the plank. If the cut isn't properly square, then that face will not form a good fit against the stator piece and the workmanship will be very inferior. For somebody who does not have a cutting table, it is a very good idea to use a mitre box in order to get a good quality cut:



The width of the mitre box limits the width of the plank which can be used and a common size for the mitre box channel is just over 90 mm. Allowing the box to guide the saw blade without forcing it and sawing gently, produces a properly square cut in the two planes needed. Planed Square Edge timber is available with a width of 89 mm and thickness 38 mm, and that should be suitable:

If we choose to use threaded rod for the axle:

then it is available in various lengths, and while it is perfectly possible to cut it to whatever length is chosen, we might as well pick a 500 mm length and save having to cut a longer length to get what we need. I suggest a 10 mm diameter rod and if the overall length is 500 mm, then the gap between the two stator pieces might be 430 mm and the overall length of timber used would then be 16 x 430 = 6880 mm or 22.5 feet. However, as it is most unlikely that any timber supplied would be exactly a multiple of the 430 mm chosen, then a slightly greater length will be needed and there will be offcuts. One big advantage of using a threaded rod as the axle is that nuts and washers can be used to clamp a rotor exactly square to the axle and then lock nuts used to clamp it permanently in place.

The axle needs to be supported in a low-friction bearing and the most readily available type is the sealed ball or roller bearing:

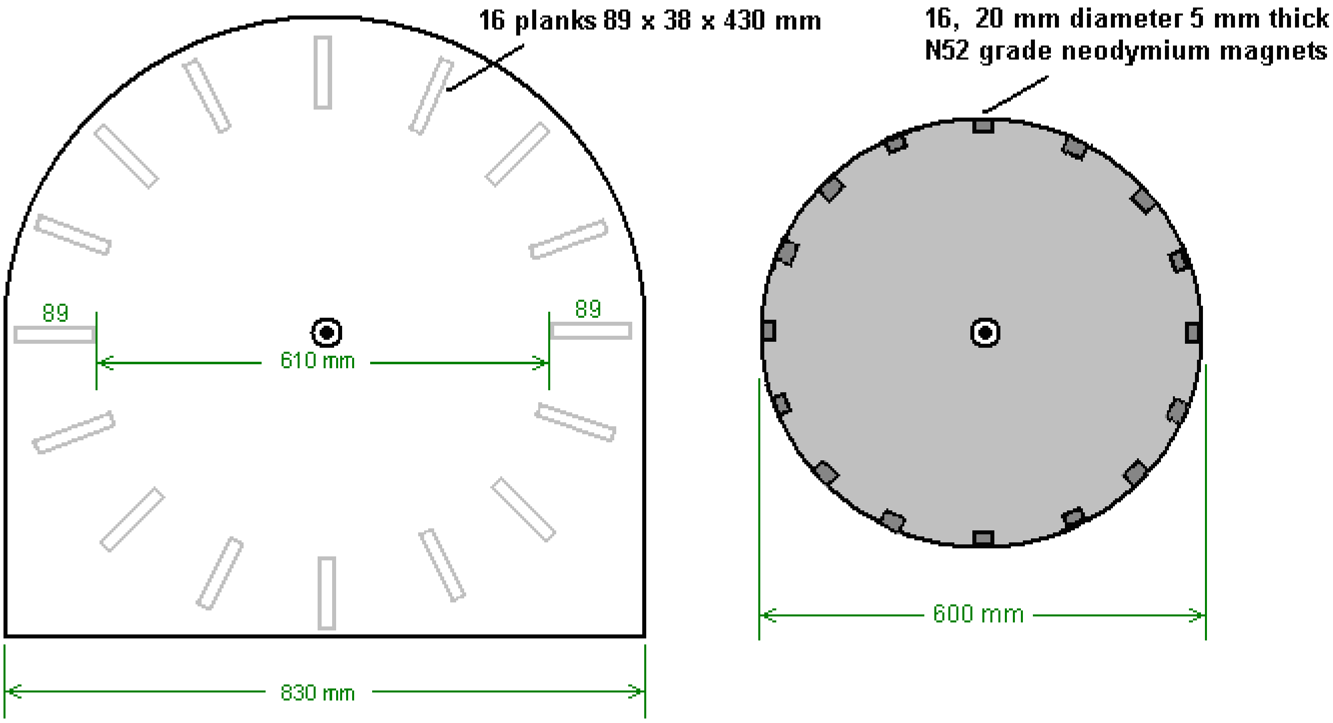
These have a rubber seal to keep dust and dirt out of the grease packed around the ball bearings inside and that spoils the free movement. One way to overcome this has the bearing outer ring clamped stationary and an electric drill used to spin the inner ring until the movement becomes low-friction. A 10 mm inner diameter bearing is often referred to as a type 6200. An alternative method is to remove the rubber seals and remove the grease by immersing the bearing in paraffin (known as 'kerosene' in the American language). Then the ball bearings or rollers inside the bearing are lightly oiled to give a very free-running bearing.

The active part of this design is the magnets attached to the outside of the rotor. We need these magnets to be powerful, and the neodymium types generally available are rated as types N35, N45, N50 and N52 with the type N52 being the most powerful. There is a substantial pulling-power difference between the different grades. I would suggest using 20 mm diameter 5 mm thick, N52 grade magnets:

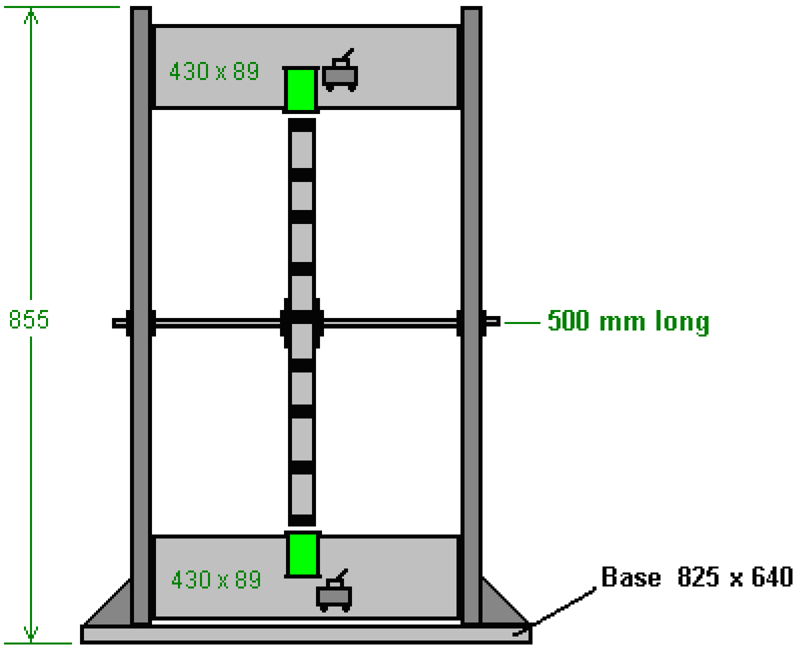
There is no need for the hole in the magnet, but if there is one, then a steel wood screw can be used to help secure the magnets to the edge of the rotor, in addition to glue. Please be very careful when handling these magnets as N52 is so powerful that they can injure you. If you have one in your hand and move your hand within 150 mm or so of another one lying on a bench, the loose one will jump off the bench and try to attach to the one in your hand. Unfortunately, your hand is in the way and the result is painful. If the flying magnet catches the skin at the edge of your hand or finger, then the grip can be strong enough to cause bleeding.

Also, when these magnets attach in a roll as shown in the picture above, it can be very hard to pull them apart. The way to deal with the situation is to slide the end magnet sideways as far as possible and then pull it away diagonally from the roll.

We are now in a position to be a bit more specific about what we want to construct:

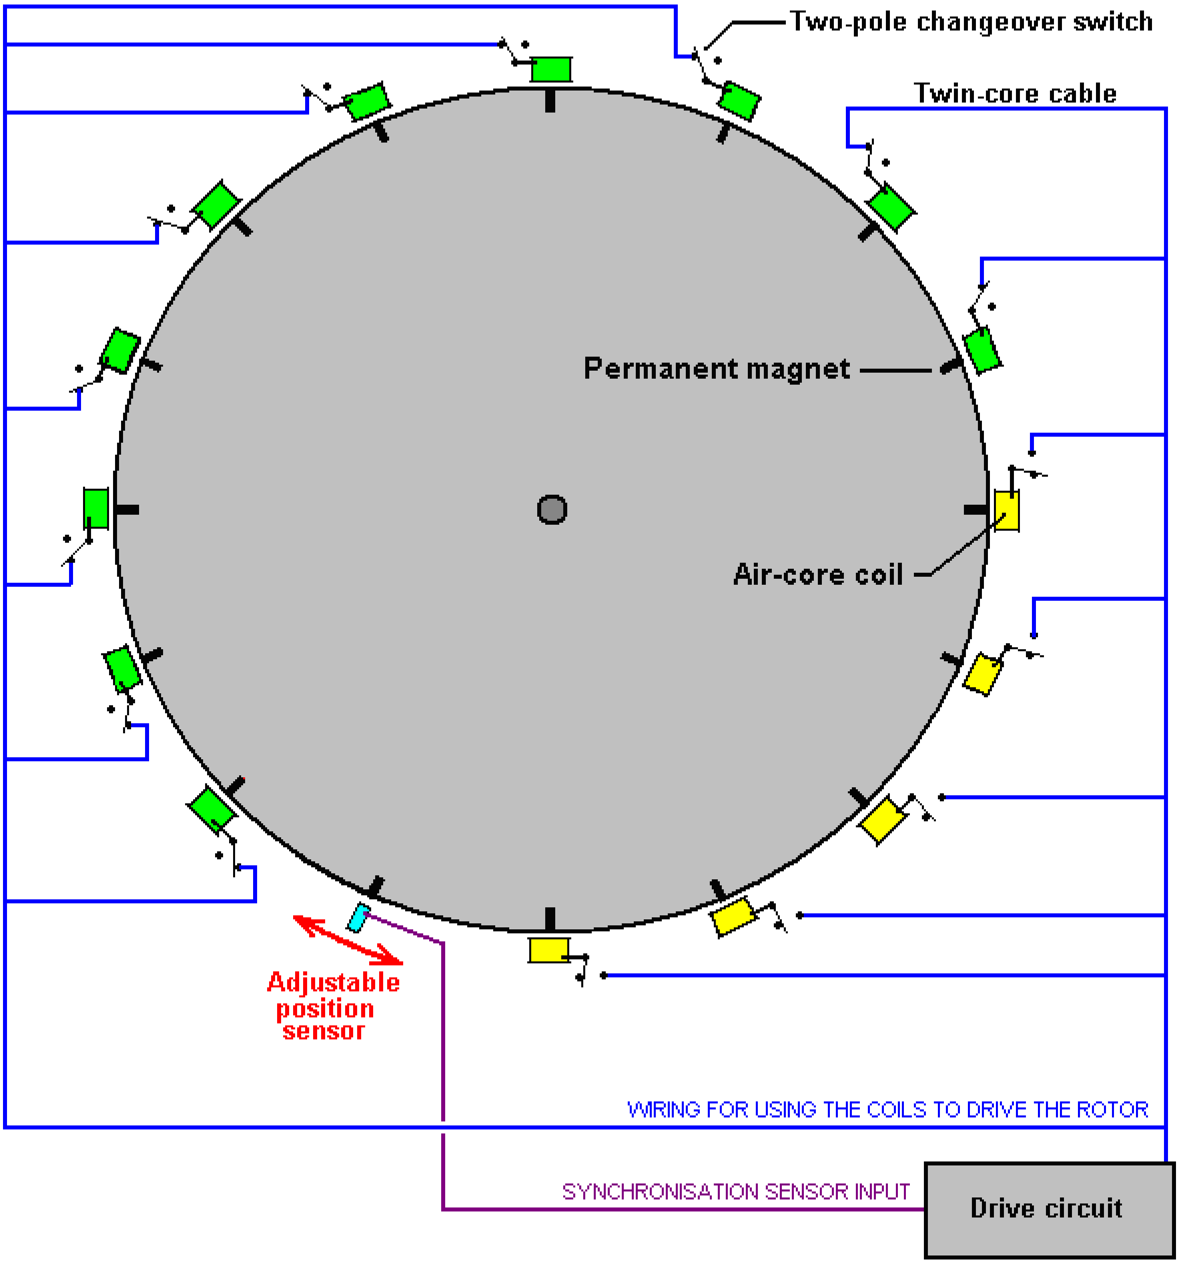


16 planks 89 x 38 x 430 mm
16, 20 mm diameter 5 mm thick
N52 grade neodymium magnets
89
89
610 mm
830 mm
600 mm



430 x 89
855
500 mm long
430 x 89
Base 825 x 640

It is suggested that the rotor is driven round by pulsing most of the coils and using the remainder of the coils to collect the output power generated by the magnets moving past them. The general arrangement is expected to be like this:

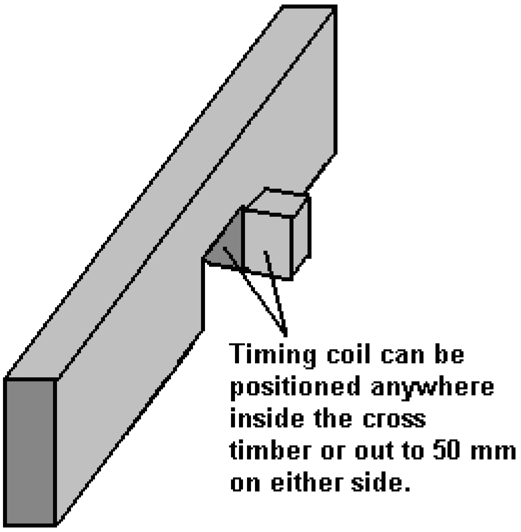


Two-pole changeover switch
Twin-core cable
Permanent magnet
Air-core coil
Adjustable position sensor
WIRING FOR USING THE COILS TO DRIVE THE ROTOR
SYNCHRONISATION SENSOR INPUT
Drive circuit

With this arrangement which was intended to be a development and demonstration unit, a single pole two way ("changeover") switch is used with every coil. This allows any coil to be changed from acting as a power collection coil to be a rotor-powering coil by just changing the switch position. If the positions of the switches are as shown in the diagram above, then ten of the fifteen coils act as drive coils and are coloured green in the diagram. The sensor is adjusted so that the drive circuit delivers a brief energising pulse to those coils just after the magnets have passed their exact alignment position with the coils. This causes them to generate a magnetic field which repels the magnets, pushing the rotor around.

Before going any further, we need to note the fact that in this particular design, the pulse timing is controlled by the physical position of the sixteenth coil. The coil movement has to be in the direction of the rotor movement, whether in the direction of rotation or alternatively directly against the direction of rotation. When setting up the device, the timing coil position (shown in blue) is moved very slowly to find the position which gives the best performance. While the original builders wanted to demonstrate an output power greater than the input power, we would like to achieve a good deal more than that, getting the device to power itself and have a useful power output for other equipment. Consequently, having an adjustable timing coil would be a good idea. For that, we can cut a slot in one of the cross timbers of the stator and attach a strip at right angles so that the timing coil can be supported and moved either towards the incoming magnet to get an earlier pulse, or away from the incoming magnet so that the pulse is generated later.

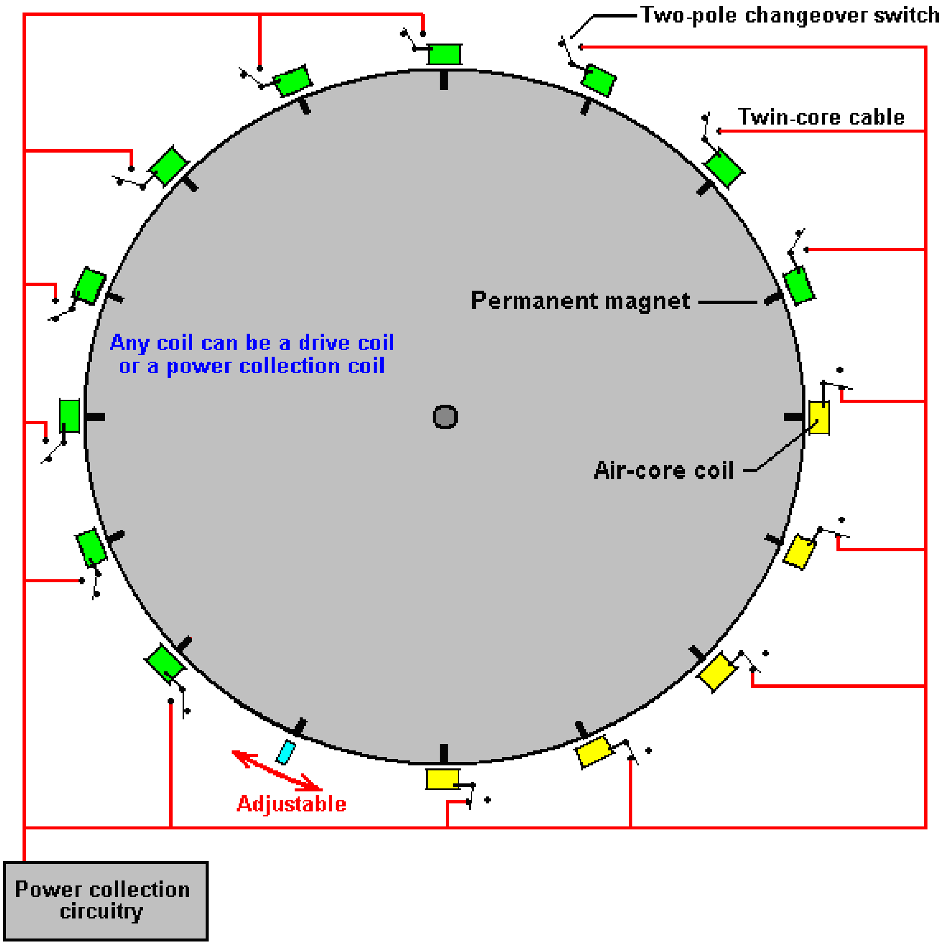
As adjustments will be made to this setting, it is probably easiest if the adapted plank is at the top of the set of sixteen planks, rather than at the bottom as shown in the electrical diagram. The arrangement might be like this one which gives the sensor coil a 138 mm wide mounting area:



Timing coil can be positioned anywhere inside the cross timber or out to 50 mm on either side.

A really major advantage of this type of drive using a pulsed coil to push a magnet on its way, is that the working voltage does not have to be maintained at or near any particular design voltage. In the original case, a small lead-acid battery was used to drive the generator. I am not a fan of lead-acid batteries although they have their uses. I dislike them because they are big, heavy, expensive and they waste half of the power which you feed into them. If you feed one amp into a lead acid battery for one hour, you can only draw one amp from that battery for half an hour. That is an efficiency of only 50% and other batteries do better than that. NiMh batteries are 66% efficient, so you could get your 1 amp of current back for 40 minutes. The best of all is a capacitor as it is 100% efficient, but more about that later.

Each pulse powering the rotor is very brief, so very little power is needed to accomplish this pulsing. As mentioned before, any number of coils can be switched to provide this driving force. With the original wheel construction, the best number of drive coils was found to be ten.



Two-pole changeover switch
Twin-core cable
Permanent magnet
Any coil can be a drive coil or a power collection coil
Air-core coil
Adjustable
Power collection circuitry

With that particular arrangement, five of the coils gather energy while ten provide the drive. For the sake of simplicity, the diagram shows the five collection coils adjacent to each other and while that would work, the wheel is better balanced if the drive coils are evenly spaced out around the rim. For that reason, this switching would actually be selected to give five sets of two drive coils followed by one pick-up coil as that gives a well balanced thrust on the wheel.

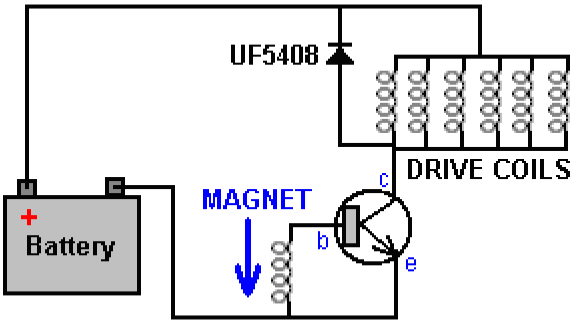
However, we may choose a more powerful arrangement. Firstly, the power-gathering air-core coils are wound without any kind of power enhancing core, probably with the notion that there will not be any drag when a magnet passes a coil of that type. That is the case if the coil is unconnected and so is useless. That is not the case if the coil is connected and is contributing output power, because doing that causes a current to flow in the coil, and current flowing in a coil produces a magnetic field and that magnetic field definitely interacts with the passing rotor magnet.

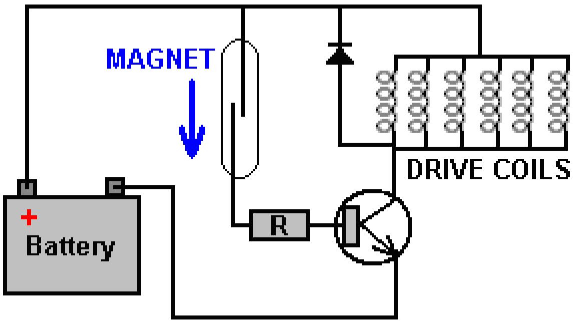
I will suggest a few alterations which I suspect will make a major difference. You can ignore them and replicate the original build exactly, or you can try some or all of them either as part of the build or as future modifications. It is your project and you are free to do whatever you choose.

As a first step, I would upgrade the coils. A coil is generally considered to be one long length of wire wound around a tube of some kind, to form a helix. Nikola Tesla patented a bi-filar coil design which has much stronger magnetic properties, and I suggest that the drive coils (if not all coils) are wound in that way. To wind a bi-filar coil, you use two strands of wire simultaneously. That is a great advantage because the coil spool only needs to be turned once to get two turns on the coil, and that halves the effort if you are winding your coils by hand. When the coil is wound, then the end of strand 1 is connected to the beginning of strand 2. That results in a helically wound coil just as before, but the major difference is in the physical position of each turn inside the coil. Tesla's patent US 512,340 describing this technique, puts it forward specifically for electromagnet coils as the magnetic effects of the current flowing through the coil are considerably increased by using a bi-filar coil.

The coils powering the rotor are driven by a transistor. The transistor is switched on by the passing rotor magnet. That switching can be done with a coil of wire feeding the generated current into the Base (or Grid) of the transistor. That current flow turns the transistor on, but as soon as the magnet passes by, the current is no longer generated and so the transistor switches off again.

An alternative is to use a reed relay which is just two strips of thin metal inside a glass tube. The strips form a switch which closes when the rotor magnet comes near. That switch can be used to feed a small current from the battery into the Base (or Grid) of the transistor through a current-limiting resistor "R". These two arrangements look like this:



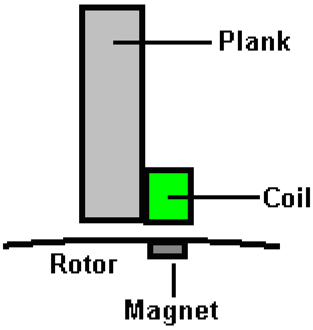


If you are familiar with electronics, then a Hall-effect magnetic switch or an optical switch could be used as alternatives. Personally, I think that the pick up coil is the most simple and effective way of timing the drive pulses from the battery.

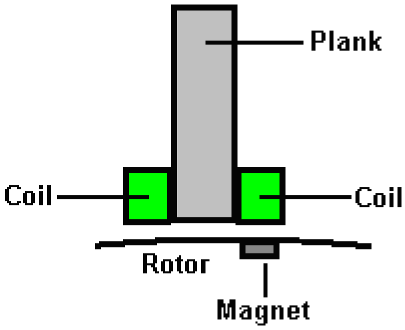
Both of the circuits shown above have a diode placed between the transistor collector and the Plus of the battery. Most people will tell you that it is there to protect the transistor, but in this circuit, the diode also feeds back-EMF power from the drive coils back into the battery and Robert Adams usually places a capacitor across the diode when doing this.

As an additional method of boosting the power of the unit I suggest that additional power output coils are used. If the build has a 600 mm diameter then the magnets are spaced out at 117.8 mm centres and the gap between the magnets is 97 mm (4.6 inches) and the gap between adjacent cross planks is 60 mm (2.3 inches).

Another potential upgrade is to mount an extra pick-up coil on the reverse side of each plank. The original build had a construction like this:

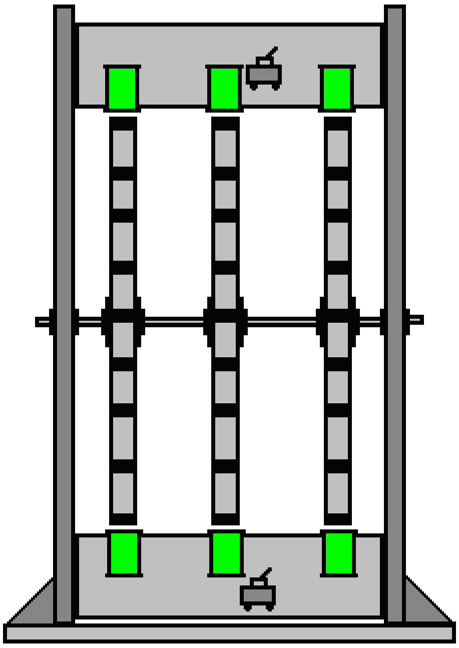


This arrangement has sixteen coils, each mounted one per plank. That is a very simple construction. However, it is possible to double the number of coils while still maintaining the great simplicity of the construction. The way to do that is to mount a second coil on the other side of the plank like this:



If the rotor is 600 mm in diameter, then the coils should not have a diameter of more than 38 mm. If 40 mm (1.5 inch) diameter coils are wanted, then make the rotor diameter 620 mm. Using these additional coils with this method does not have all the coils spaced out evenly around the rotor, but that does not matter in the least. Leaving the driving circuitry unchanged, there will still be 16 evenly spaced pulses for every 360-degree movement of the rotor. The additional coils are passive and pick up energy from the magnets as they pass by. However, with a coil on both sides of the plank, the new coils are only about 5 mm away from the next of the original coils and that is close enough to pick up the magnetic field from that coil when that drive coil is pulsed.

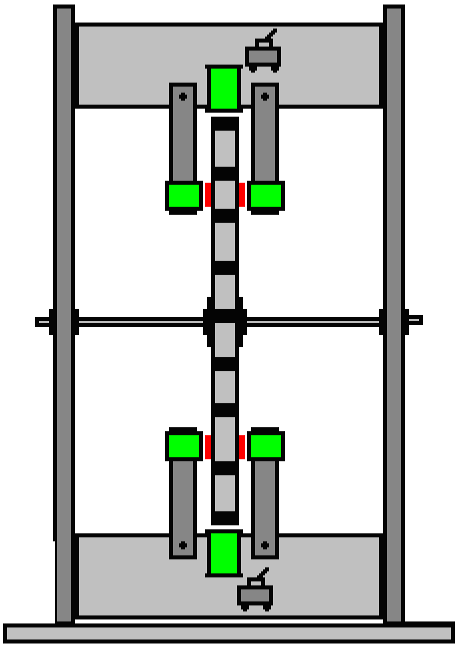
One additional power upgrade would be to have two or three rotors on the one shaft. Doing that has considerable advantages, not the least of which is that each additional rotor can be added at a later date when it is convenient to do so. The arrangement looks like this:

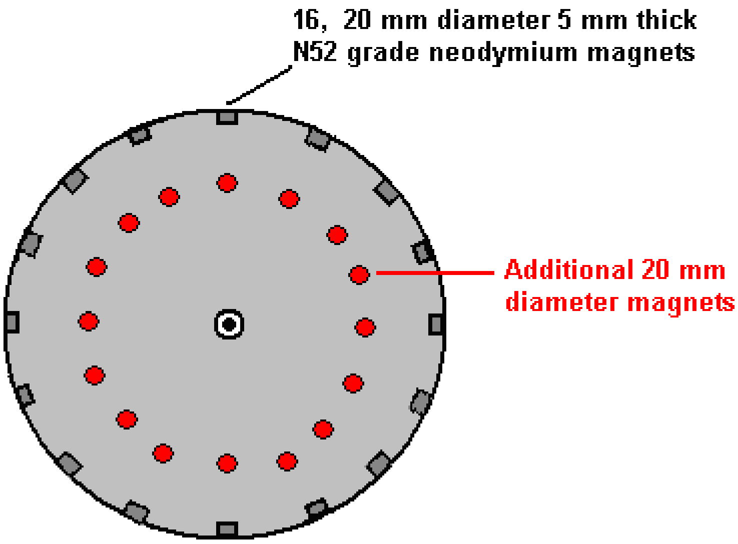


There is no need for any additional circuitry as the original rotor controls the timing of the pulses from the drive coils and the magnets on the rotors are aligned exactly. The additional rotors can have drive coils, power gathering coils or any mixture of the two types.

While the original diagram shows both the drive coils and the power gathering coils as being connected in parallel, it is likely that the power gathering coils at least would be better off connected in chains of twos or threes in order to raise the output voltage before being connected in parallel to increase the available current.

There is also the possibility of putting additional magnets in the face of the rotor and additional coils on both sides of the rotor, the coils being supported on arms coming off the planks:

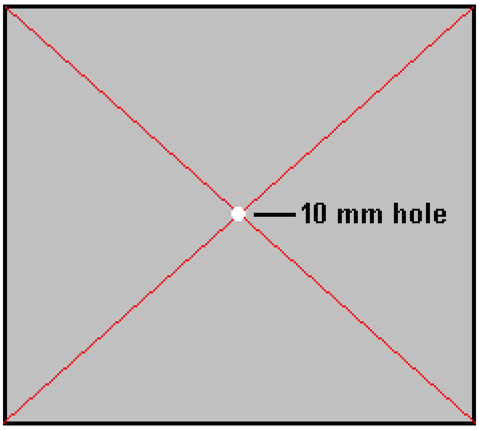




But this level of modification is probably more advanced than is needed at this point in the development, so let's add some more detail to the most simple version.

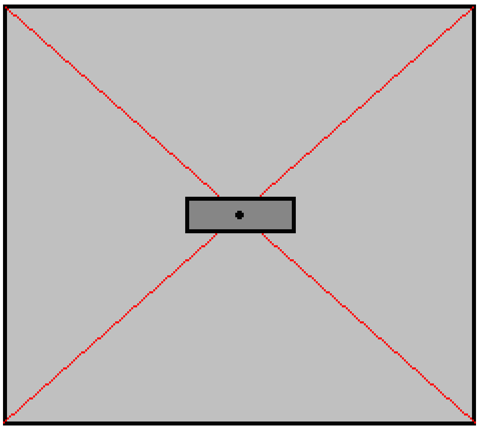
The rotor can be made from any non-magnetic sheet material which is rigid and which will not warp. The sheet needs to be larger than 600 x 600 mm in size. Measuring carefully, you mark a point which has 300 mm clear on all sides. If the sheet is nearly the correct size and the offcuts are not likely to be much use for anything else, then marking where the diagonals from the edges cross gives a suitable point.

Next, you drill a 10 mm diameter hole at that central point:



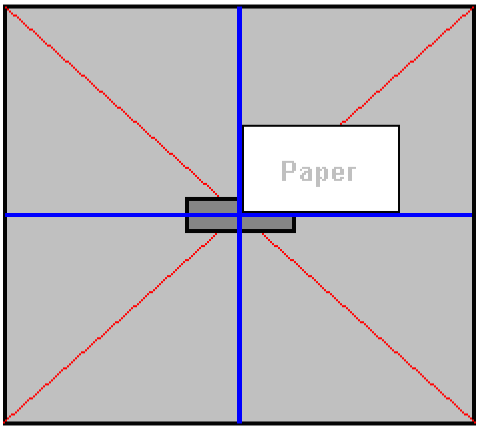
While this sounds easy, it is probably the single most difficult part of the entire construction. It is very difficult to hold a hand drill perfectly vertically, especially when you have to look at it from one side because the body of the drill blocks the view from vertically above. The board is too wide to use a normal drill press, and the notion of using something drilled in a drill press as a guide to the vertical while attempting to get the drill bit on the marked point which the guide now obscures is usually a recipe for disaster. To get over this problem, we will drill a sloppy hole by hand and use two nuts and two washers to force the rotor into an exactly vertical position as well as holding the rotor in place permanently. However, even though it is going to be a sloppy hole, do your best to drill it as square and upright as possible.

Next, cover the hole over with tape pulled into a smooth surface and mark the exact centre of the hole on the tape:

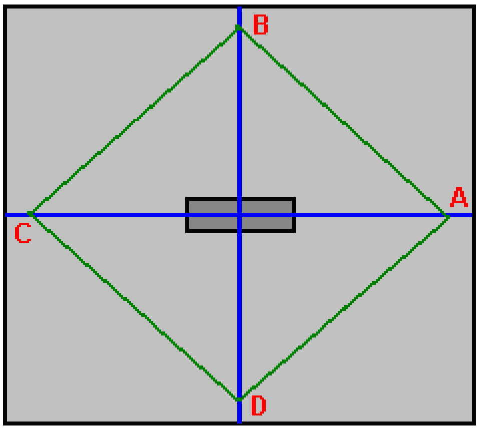


Forget all previous markings. This central dot is what we work from now as everything is exactly related to that point, and only that point.

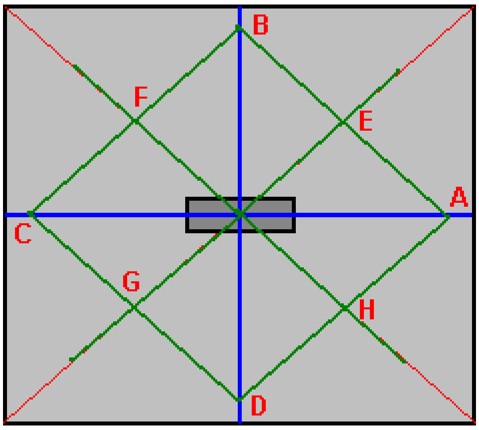
Now, draw a line through the centre point, at any convenient angle. Then a second line through the point at exactly 90 degrees to the first line. If you wish, you can use a sheet of paper to get the 90 degrees:



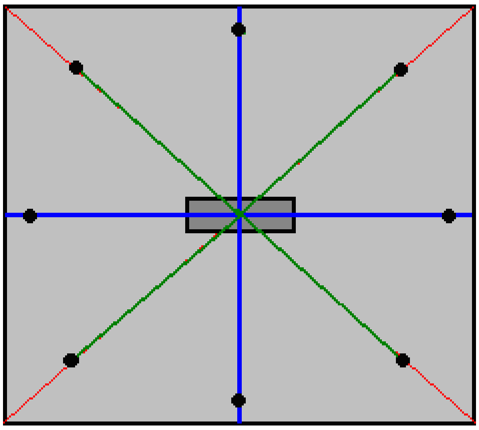
The next step is to measure off exactly 300 mm from the central point along each of those four lines and connect those points "A", "B", "C" and "D" with straight lines:



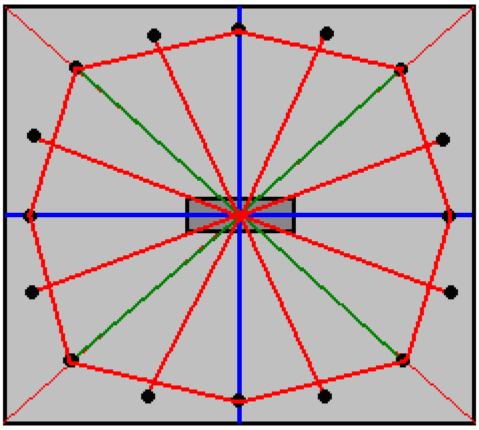
Measure the length A to B, B to C, C to D and D to A. Those lengths should all be exactly the same. Now, mark the centre point of each of those four lines (points E, F, G and H):



and draw a straight line from the centre point through those four points and mark off exactly 300 mm from the centre point on each of those lines. This has now located 8 of the 16 magnet positions in exact relationship to the central hole:



The next step is to join each of those 8 points to the next one, mark the centre point on each and draw a 300 mm long line from the centre point through those points to show the positions of the final 8 magnets:



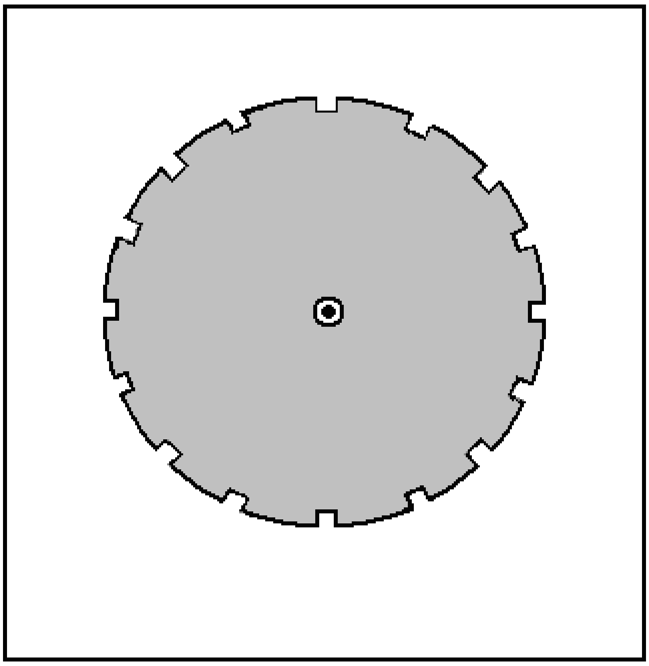
We now have the exact positions of all sixteen of the magnets, so remove the piece of tape and push your 10 mm diameter drill bit into the hole. Tie a loop in a piece of string and put the loop over the drill bit. Take a pencil and place the tip on one of your marked magnet positions, and then with the string wrapped round the pencil low down near the board, adjust the string so that it is tight and mark a 300 mm radius arc through all of the magnet positions. This is the edge of the rotor.

Why didn't we just do that instead of all the measuring? Because the string method is very easy to get badly wrong and we want the rotor to be as accurate as we can make it.

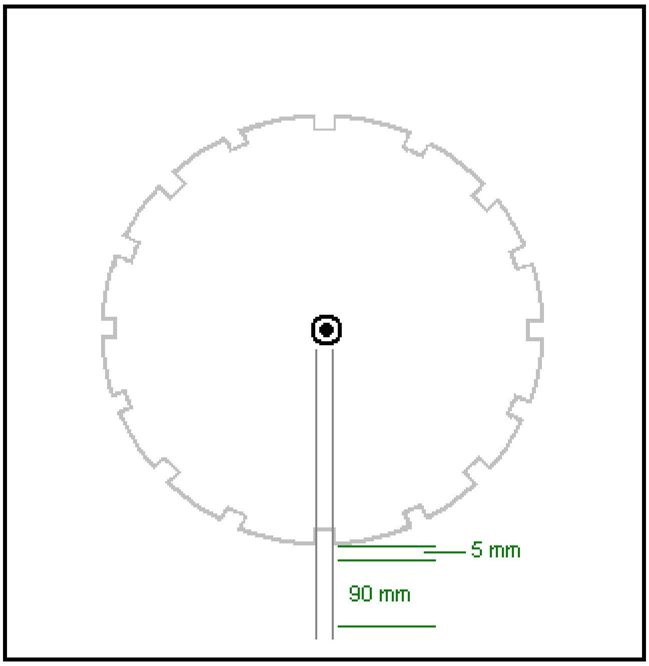
We now want to cut out the rotor (being careful not to erase the lines showing where the magnets are to be attached) and the inclination is to grab a power jig saw as that is the easiest way. However, I recommend that you don't do that as power tools are very good at getting things wrong in less than one second. Cutting carefully and slowly using a coping saw should give you a perfect rotor whose edges can then be sanded. The advantage of a coping saw is that the blade angle can be set to allow very long cuts near the edge of a piece of material:

When the rotor has been cut out, mark 20 mm lengths at the magnet points and use the coping saw to remove a 5 mm deep slot the full width of the rotor material along each 20 mm length. This allows the magnets to be flush with the edge of the rotor. The rotor is the only precision item in the entire construction, so the most difficult part has now been completed.

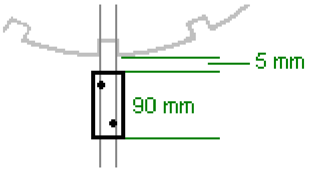
As it is more convenient to attach the coils to the cross planks before assembling the outer frame of the stator, we will cut the necessary pieces but not assemble them until after the coils have been completed. To cut out the side pieces, place the rotor on a thick sheet of material such as chipboard, Medium Density Fibreboard, plywood, block board or similar, in a position where there is 135 mm (5.5 inches) clear all around it. As the rotor is 600 mm in diameter, the side panel needs to be at least 830 mm square:



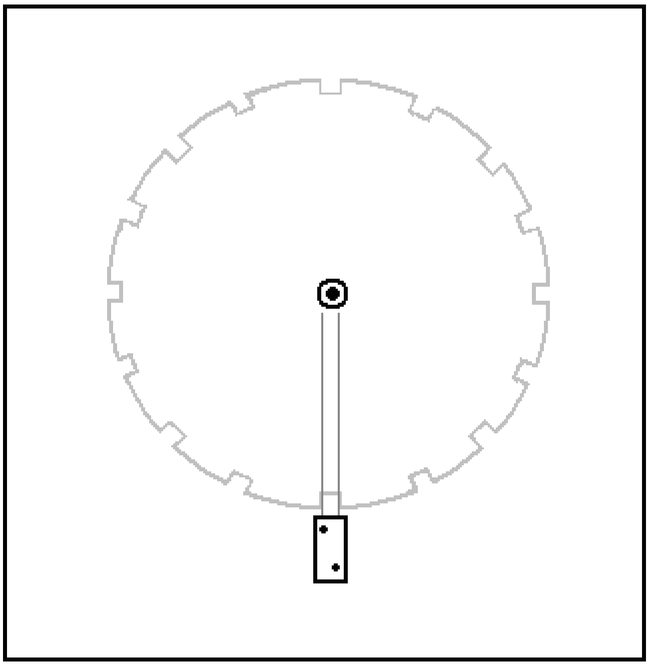
Mark the sheet through the rotor hole, remove the rotor and drill a 10 mm hole through the sheet. Place the drill bit in the hole in the sheet and slide the rotor down on to the drill bit. This matches the rotor exactly with the stator side panel. Carefully mark around the rotor with a pencil and remove the rotor and the drill bit.



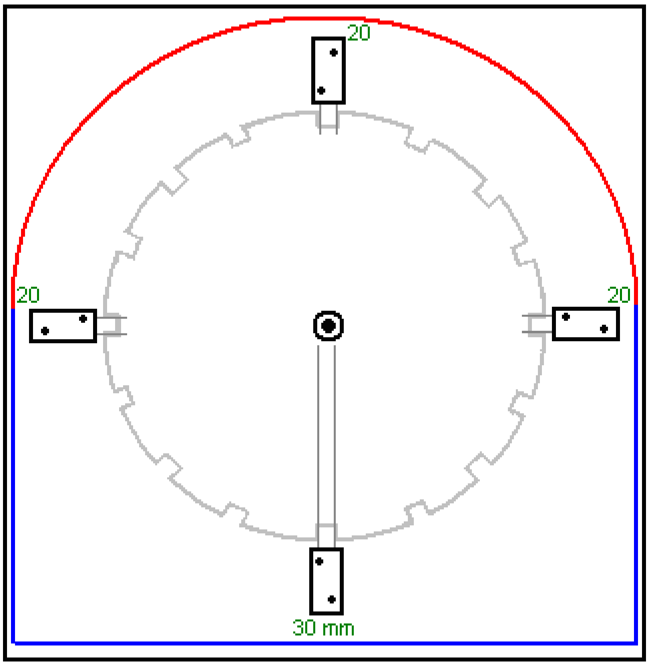
Draw parallel lines 20 mm apart, running from the centre of the rotor outline, through each of the magnet slots. Allow for a 5 mm gap between the rotor and it's matching plank and mark off a 90 mm length as shown above. This is to mark out the position where the plank will be attached to the side panel of the stator. As the plank is 38 mm wide, it will extend 9 mm outside the lines like this:



After the position of the plank end has been outlined, drill two holes to take the screws which will hold the two stator side panels together. When the first one has been completed, it will look like this:



That process is repeated for all sixteen planks, and that outlines the stator side panel well enough to allow it to be completed:



Leave 30 mm below the lowest plank position and 20 mm at each of the two side planks, and draw the horizontal and vertical lines shown in blue in the diagram above. Then, putting the drill bit back in the hole and using a piece of string and a pencil to improvise a very large compass, draw the red arc shown above. That completes the outline of the side panel of your stator, which can now be cut out. This cutting is not critical in any way, but it would be nice to have it looking neat. The completed side panel is now placed on a second panel and a pencil mark is made to show the position of the drilled hole. The second panel is drilled with a 10 mm diameter hole and the drill bit is used to make sure that the two holes align perfectly. A pencil line is now traced around the outside of the completed side and the second side panel is then cut out along that line.

The 10 mm drill bit is now used to align the rotor and the second side panel, taking great care to align the rotor in exactly the same position as on the first side, and the end positions of the planks marked out and drilled ready to take the screws.

Next, you take your two bearings and treat them to make them as free-spinning as possible, then, measure carefully out from the hole drilled in each of the two stator side panels and mark a circle of exactly the same diameter as the outside of the bearings. Use a power jig saw to cut out the circle staying just inside the line. This gives a rough opening which is just too small for the bearing to fit into. Enlarge the hole very gradually using a wood rasp or coarse sandpaper until a bearing can just be forced into the hole. Leave the bearing in place but don't do anything further to attach it at this time – that will be done later when the axle is in place and the rotor has been proved to spin freely.

The base panel is just a rectangle 850 x 500 mm in size, but we are not ready to assemble the unit just yet as we need to wind the coils and attach them to their support planks ahead of assembling the generator.

We need to choose a wire diameter, coil dimensions, number of turns per coil and style of winding. Those items are the things which are changed when a builder says that he is "tuning" his generator to get maximum performance. It sounds much more impressive to say that you are "tuning" rather than to say that you are experimenting with different coils. So, let's get started with our choices.

The thicker the wire used, the greater the current which it can carry, but the fewer turns which will fit on to any particular coil spool. Also, the thicker the wire, the shorter the length which you get when buying it by weight.

The thinnest wire, say, SWG 40 which is about one tenth of a millimetre in diameter, is liable to break when you wind it unless you are very careful and wind gently. The really thick wire is a bit stiff and can be a bit difficult to wind. However, we are not going to encounter those problems in this job as current handling capacity needs to be taken into account. The question we need to answer is "how much current can we draw from a coil when we swing a magnet past the coil?" and the answer is "probably not much". So, we take a look at the table which shows the currents which the different wire sizes can carry comfortably:

AWG	Dia mm	Area sq. mm	SWG	Dia mm	Area sq. mm	Max Amps	Ohms / metre	Metres Per 500g	Max Hz
1	7.35	42.40	2	7.01	38.60	119			325
2	6.54	33.60	3	6.40	32.18	94			410
3	5.88	27.15	4	5.89	27.27	75			500
27	0.361	0.102	28	0.376	0.111	0.288	0.155	500 m	130 kHz
28	0.321	0.0804	30	0.315	0.0779	0.226	0.221	700 m	170 kHz
29	0.286	0.0646	32	0.274	0.0591	0.182	0.292	950 m	210 kHz
30	0.255	0.0503	33	0.254	0.0506	0.142	0.347	1125 m	270 kHz
31	0.226	0.0401	34	0.234	0.0428	0.113	0.402	1300 m	340 kHz
32	0.203	0.0324	36	0.193	0.0293	0.091	0.589	1900 m	430 kHz
33	0.180	0.0255	37	0.173	0.0234	0.072	0.767	2450 m	540 kHz
34	0.160	0.0201	38	0.152	0.0182	0.056	0.945	3000 m	690 kHz
35	0.142	0.0159	39	0.132	0.0137	0.044	1.212	3700 m	870 kHz

Looking at the smallest wire size shown, it can carry 44 milliamps, but it is so thin that it would be difficult to handle. I have wound successfully with SWG 40 but it is not the most convenient. I would suggest SWG 36 which is AWG 32 and has a diameter of nearly one fifth of a millimetre. It can carry 91 milliamps continuously and a good deal more when it is the pulsed current produced by a magnet passing by. The table shows that if we buy two 500 gram reels of SWG 36, then we receive a length of three thousand eight hundred metres of wire for winding our coils. Every extra coil that we wind, increases the power of the generator, so we will be winding a lot of coils.

It is not at all difficult to wind these coils, but it will take a few days. For people living in the UK, the best supplier is the Scientific Wire Company who manufactures the wire. In November 2015 they sell two 500 gram reels of SWG 36 wire (their Ref: SX0190-2x500) for just £18 including tax at http://wires.co.uk/acatalog/SX_0190_0280.html and that is 'solderable' enamel which just burns away when you solder to it, which is enormously helpful, especially with very thin wire.

Alternatively, if you choose two 500 gram reels of SWG 37 wire with 72 milliamp current carrying capacity (their Ref: SX0170-2x500) at http://wires.co.uk/acatalog/SX_0140_0180.html then the cost is £19.72 but the wire length has increased to four thousand nine hundred metres, which is an extra 1,100 metres of thinner wire.

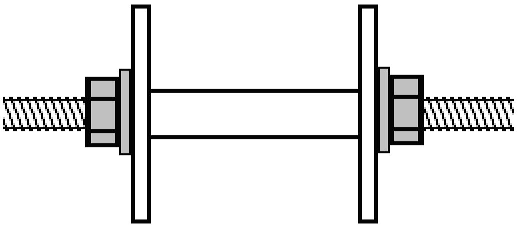
Please remember that the wire current carrying capacity is not all that important as many coils are involved. For example, if each coil is contributing 30 milliamps (which is well inside the ability of the wire to manage) and there are ten coils connected in parallel, then the combined current is 300 milliamps which is well outside the capacity of any single wire to carry. Just remember that if they are connected in parallel and feeding the power away, then you need a much larger diameter wire to carry that combined current from the set of coils to its destination.

When winding a coil, you need to choose the starting diameter of the coil. The magnetism produced by a coil increases with the number of turns, more turns produces more magnetism. The magnetism also increases with the area inside each turn of the coil, the bigger the area the bigger the magnetism. The snag is that the bigger the enclosed area, the greater the wire length needed to complete each turn of the coil wire. So, the question is should we use a small diameter coil shaft or a thick coil shaft? In this case we want a large number of turns on a coil of not more than 38 mm diameter, so we will choose a narrow tube for our coils.

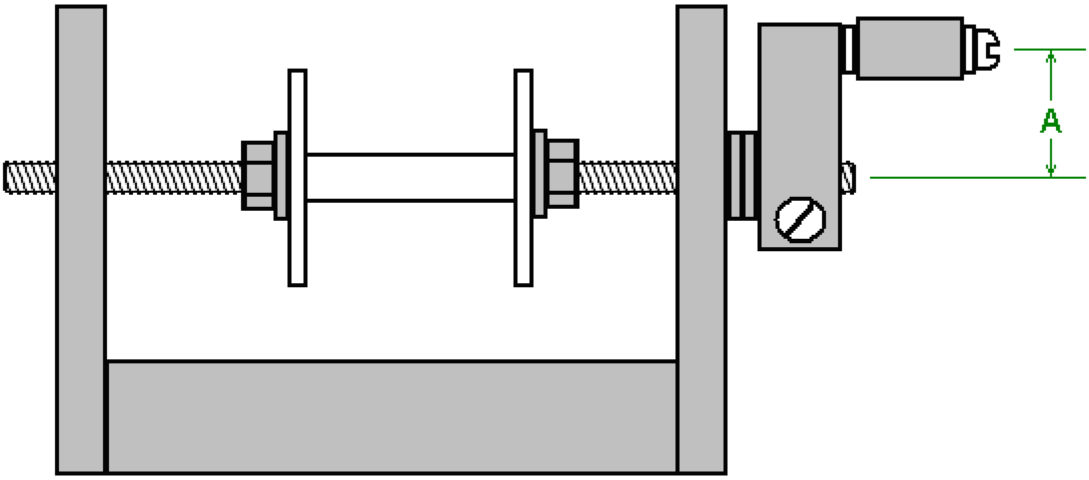
We can make up coil spools quite easily if we use a power drill and a hole saw set like this:

These saw sets normally have a saw which has an inner diameter of 35 mm. That doesn't sound very large but the wire being used does not build up much depth of turns when being wound, even with a large number of turns in the coil. A small sheet of 3 mm thick Medium Density Fibreboard ("MDF") can easily be drilled using the hole saw, and each drilling produces one perfectly round disc with an exactly centred hole in the middle. Two of those can be glued (at exact right angles to the central shaft) on to a tube to form a spool of the size wanted. If it is available, plastic sheet could be used instead of the MDF. Plastic tube of 8 mm diameter and an inner diameter of 6 mm is often available on eBay, but failing that, it is actually quite easy to drill a 6 mm hole through a short length, say, a 30 mm length of 8 mm diameter dowel rod. The piece of dowel is held in a vise and because it is easy to see, drilling a reasonable hole down the length of dowel is not actually that difficult.

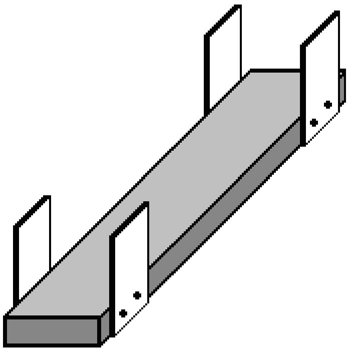
The spool can be clamped on to a standard 6 mm diameter threaded rod using two washers and two nuts or wing nuts:



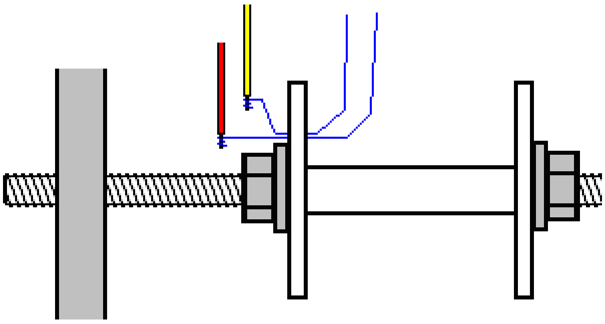
Then the threaded rod can be clamped at one end with a simple crank handle formed out of a small piece of timber, a clamping screw to grip the rod and a 20 mm length of drilled dowel on a screw to form the rotating winding handle:



A simple drilled hole in the vertical sides works perfectly well as a bearing, but keep the length "A" short as that needs less wrist movement and with it short, it is quite easy to turn the handle four times per second. A plank around 600 mm long makes a good base for the winder:



The winding handle part is at the near end and the two 500 gram spools of wire are placed one above the other at the far end. The longer the plank, the easier it is to draw wire from the large supplying spools as the angle between those spools and the spool being wound is smaller. The supplying spools are each just mounted on a dowel pushed through holes in the side pieces. Be sure to make those dowels horizontal so that the spools don't keep moving to one side or the other.



To start winding a coil, drill a very small hole in the left hand flange, just outside the washer. Thread the two wires through the hole and wind each a few times around the bared end of a short length of plastic covered wire, and join each wire to the copper winding wire by soldering it. This only takes a moment and if you have never soldered, it is very easy to learn and easy to do. Next, use a piece of duct tape to attach the thin wires firmly against the outer face of the flange of the coil spool and wrap the spare plastic covered wires around the threaded rod a few times so that they won't catch on anything when being whirled around. Trim the duct tape so that it is all on the outside of the flange and so will not get in the way of the wire which is being wound on to the coil spool.

The coil is wound by gathering the two strands in your left hand and turning the crank handle with your right hand. If you wish, you can clamp the winder to the table or workbench which you are using. The preferred way of winding is to turn the crank handle so the that wire entering the coil spool feeds on to the underside of the spool. That method of winding is called "Counter-Clockwise". If you want a clockwise wound coil, you just turn the crank handle in the opposite direction so that the wire enters the spool at the top. Counter-Clockwise is considered to be the better way to wind these coils.

When starting to wind, guide the wires close to the drilled flange. This is to keep the starting wire taught, flat and out of the way of the following turns. As winding continues, the wires are directed very slowly to the right until the spool shaft is fully covered. Then the wires are directed very slowly to the left for the next layer, and that is continued, right, left, right, left until the coil is completed. Then the two wires are duct taped to the plank so that they are kept controlled while you are busy with other things. Then the wires are cut, a few turns taken around the stripped end of a short length of thicker wire and soldered to make an electrical and mechanical join between the thick wire and the thin wire. The body of the coil is now wound with electrical tape so that none of the wire is visible, and then the duct tape is removed from the spool and the two starting soldered joints are epoxied to the flange.

There is no need to mark the wires as the start of the wires are the ends coming through the drilled hole and the ends of the wires just stick out from under the electrical tape, and a meter will tell you which start and which finish are the same wire. You need to check that anyway to ensure that the wire connections are good and that the resistance of each of the two wires in the coil is exactly the same.

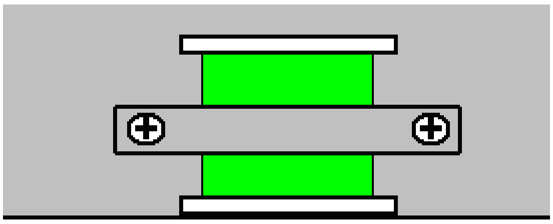
What hasn't been mention so far is the number of turns in the coil. The larger the number of turns the higher the voltage produced when a magnet passes by. A larger number of turns produces a larger amount of output power, or if it is being used as a drive coil, the greater the strength of the magnetic field produced.

There are various winding methods. One method is to choose the number of turns and count the turns as they are being wound, perhaps counting to 100 and then marking down that count and starting on the next 100 turns. That method works well enough even though it does not give identical results from one coil to the next, due to the wires not being directed in exactly the same way due to human error. I would suggest at least 3000 turns in any coil.

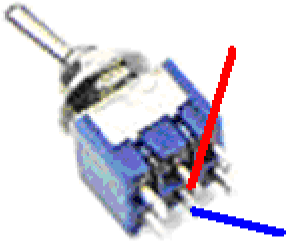
One idea which occurs to me is to take our 30 mm long, 35 mm diameter coil spool and wind two separate bifilar coils on it, one on top of the other. If that is done, then there is the option to use the inner coil as a drive coil and the outer coil as a power collection coil. The drive coil pushes the passing rotor magnet away as before, but that drive pulse also produces a magnetic field around all of the drive coil and that field will be picked up by the collection coil, in addition to the power collection from the passing rotor magnet. If it is found that this arrangement is not particularly good, then the second bifilar coil can be joined to the first one to make a much larger single bi-filar coil.

One tempting option is to just wind the coil until the spool is completely full. That is not a technique which is commonly used, but it is definitely possible. It will result in coils which have slightly different characteristics. The pushes from the drive coils will not be exactly the same, but I doubt that it would cause any great problem. The voltages from the power gathering coils will be slightly different. This means that current draw will start from the coil with the highest output voltage, but the load will quickly draw that voltage down until the on-load voltage reaches that of the second highest voltage coil, and then both will be drawn down to the third highest voltage, and so on.

So, the choice of winding style is yours. No matter which method you use, you end up with a set of 16 or 31 coils ready for installation. Irrespective of the number of coils being installed, mark the centre point on both sides of every plank. If your coil winding has left an unused section of flange on the coil spool, cut it off on one side so that the turns of wire can be attached directly to its plank. Position the coil on the middle mark and attach it to the plank in a non-permanent way, such as using a metal strap or wooden strap screwed to the plank, straddling the turns of the coil. The attachment has to allow you to adjust the coil position towards, or away from, the rotor.



Join the end of the first strand of the coil winding to the start of the second strand. If you want to use switches (and that is really unnecessary in our construction) then solder the remaining wires to the central contact of each side of a miniature two pole changeover switch:



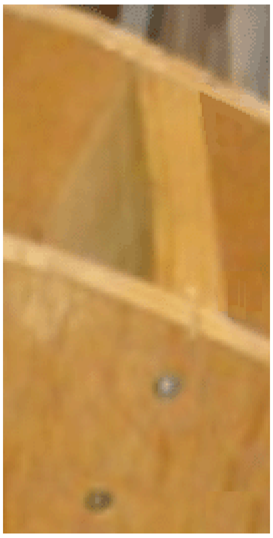
Glue a small spacer 15 mm thick, to the side of the switch and then glue the spacer to the plank. That lifts the switch up high enough to make soldering other wires to the switch much easier. The original build used single pole switches, assuming that there would be a common negative line to all of the coils. In this implementation, we would use double pole switches so that the coil can be switched into more advanced circuit configurations as we want to experiment with power collection coils connected in separate groups. We really do not need switches.

If a coil is being used on both sides of each plank, then attach the second coil to the centre of the plank's other face.

The magnets need to be attached to the rotor. It is said that the North-seeking pole is four times stronger than the South-seeking pole of any permanent magnet when used in an application of this type. If you don't know which face of the magnets is North, then take a stack of two or four magnets and suspend them on a thread so that they are roughly horizontal. After a few minutes, the magnets will align along a definite line and the magnet face which is facing towards the North is the North-seekng pole face. If you don't know which direction is North from where you are, consult a map, of if the Sun rises in the morning and you face the rising Sun, then North is on your left. Once you have established which magnet pole is North, then the attraction or repulsion of the other magnets shows which is their North pole face.

Epoxy the magnets in place on the rotor edge with the North pole face facing outwards. Some people are inclined to put duct tape around the rotor outside the magnets to make sure that the magnets don't fly off the rotor when it is spinning. It is my experience that rotors of this type spin slowly at one revolution per second or slower, and that speed will never, ever, dislodge a rotor magnet, and if it did, there would be no significant energy in the loose magnet anyway, but if you feel inclined to do so, apply a 20 mm wide strip of duct tape on top of the magnets.

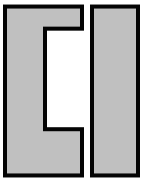
We are now ready to assemble the main components of the generator. People will have different ideas about how this should be done and there are various opinions about the best way. The cross planks will be attached to the sides of the stator using two screws on each side of every plank. That allows the unit to be taken apart later on if that should be necessary. The screws of the original were placed like this:



Personally, I would like the screws to be offset so that neither is on the centre line of the plank as that is the weakest arrangement, and so I suggest that the two screws are positioned one third of the way in from the plank edge as that gives a stronger connection with the screws 13 mm apart and not stressing the timber alomg one plane.

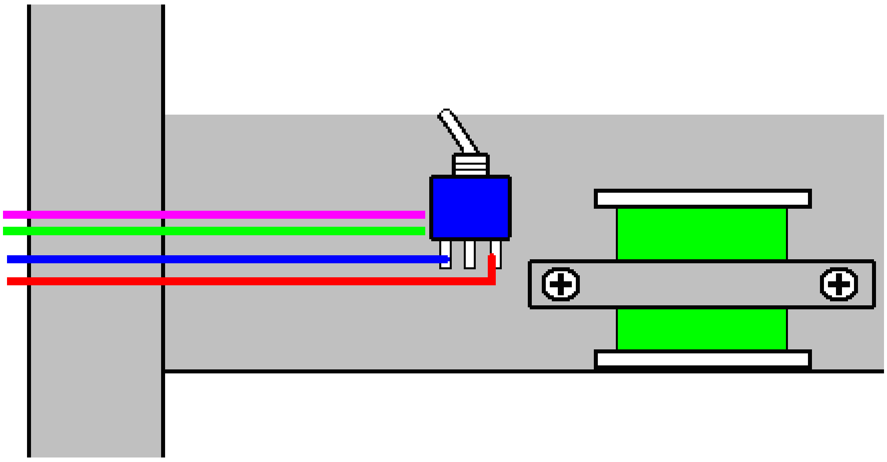
When the two stator sides are connected together by the planks, it is quite difficult to get at the planks half way up the stator. To overcome that difficulty, we can attach the planks to one side and make all wiring connections to the coils and switches. Those wires can then be run along each plank and through the stator side so that they will be easily accessible when the unit is fully assembled. It is very much easier to have the wiring on the outside, both for understanding it initially and for making changes afterwards if experiments are tried in the search for optimising the performance of the generator.

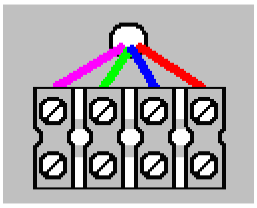
You would think that connecting a cross plank to the stator side would be ever so easy. It actually isn't all that easy and getting the screws set correctly and the plank exactly in place is not a trivial task as the screws tend to push the plank out of position. One way to overcome this and get an accurate result is to clamp the end of the plank firmly in place before driving the screws into the plank. That can be done using two pieces of scrap timber:



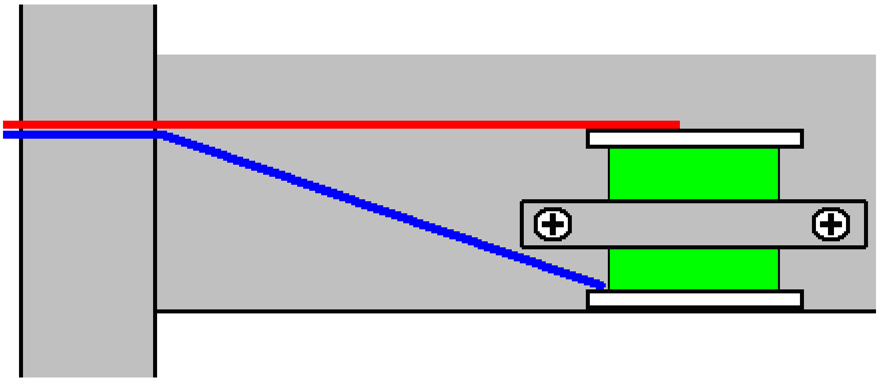
The piece on the left is cut so that a plank fits tightly in the cut out. The opening is positioned exactly where the plank should go and the piece clamped securely to the stator. The second piece is then clamped to the stator so as to complete the enclosure. This allows the plank to be pressed securely into place against the stator and the screws driven in while pressure is applied to keep the plank pressed securely against the stator with no chance of movement or any gap allowing screws to be driven in at an angle and causing a mismatch and the subsequent weakness of an inferior join. Clamping becomes impossible for the lower part of the side panel because of the increasing distance of the plank from the edge. In that area, the guide can be screwed to the inside of the side panel using short screws which do not go all the way through the side panel. The guides have to be kept fairly narrow as there is not much clearance between adjacent planks.

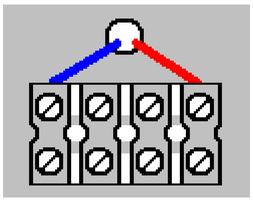
The four switching wires from the switches, or the two coil wires is switches are not being used, are run through the side of the stator and connected to an ordinary screw terminal strip:





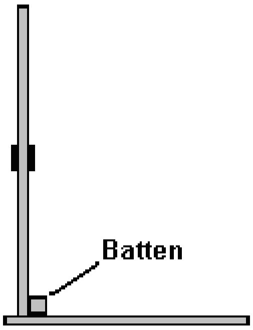
This arrangement allows complete flexibility for any arrangement of interconnections, but there is a more simple arrangement which needs no switches and that is to run the two coil wires directly out to a screw terminal strip and then make all of the subsequent interconnections with a screwdriver:



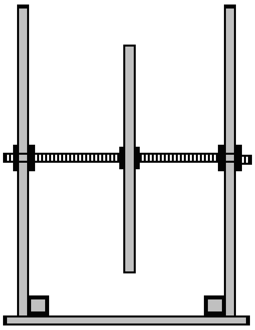


Although some coils can be connected with just two screw terminals, I suggest that four are allocated to every coil. That allows circuitry to be constructed using the terminal strips themselves.

When all of the cross planks have been attached to one of the stator side panels, attach that side to the base plate. That can be done by screwing a wooden batten to the base plate and then screwing the side panel to the batten, ensuring that the side panel is exactly vertical.

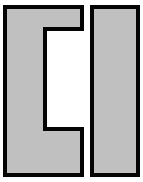


Then, put the rotor in position, through the bearing in the stator side panel, slip the other end of the axle through the bearing in the second side panel and attach the second side panel to the base plate:



This diagram does not show the planks attached to one side as including them would not be helpful as they would conceal the main details.

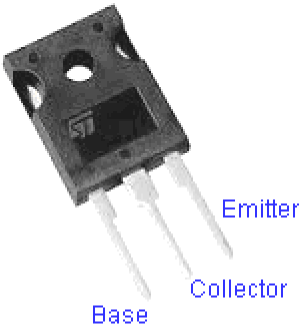
Ensure that the base is horizontal and both sides are exactly vertical and then attach the planks to the second side panel using the clamping pieces:

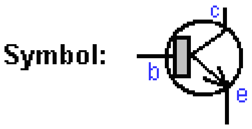


Once most of the planks have been attached, the base (with the battens attached) can be removed temporarily in order to make the remaining plank attachments easier to reach.

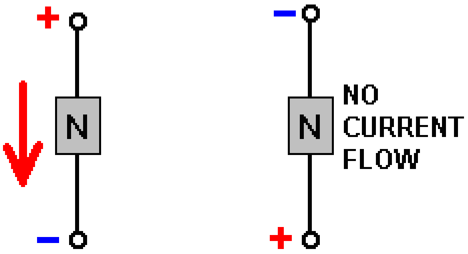
At this point, most of the construction is completed with the base, two side panels, rotor with magnets, sixteen planks and one full set of coils with their connections carried through one stator side to screw connector terminals. So now we are ready to wire up the connections and run the generator.

We use a transistor to power the generator. There are lots of different transistors and so we need to choose one. A very popular and powerful one is the 2N3055 which in its more convenient more recent packaging is called the TIP3055 transistor looks like this:

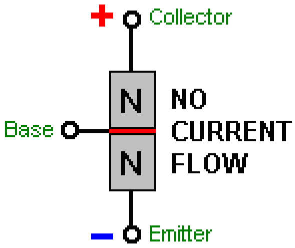




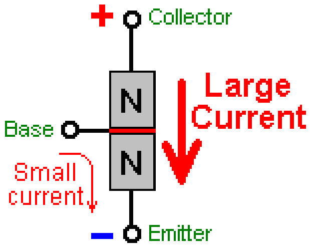
This transistor is popular and is available in many different countries. Transistors are basically, very simple devices to understand. They are made of two pieces of N-type silicon separated by a very thin layer of P-type silicon. The "N" and the "P" just stand for "Negative" and "Positive". It works like this: If you have a block of N-type silicon (which we call a 'diode') and connect a battery across it, current will flow **provided** that the battery is connected the right way round:



A transistor is two of those N-type silicon blocks separated by a very thin layer of P-type silicon to control the operation. The P-type forms a barrier when the N-type silicon would normally conduct a current:



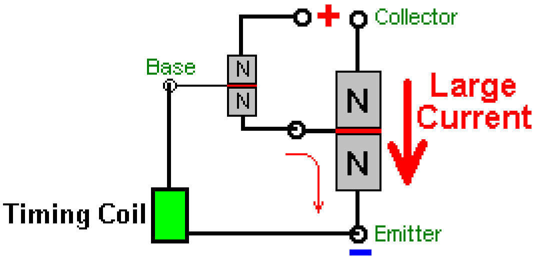
However, if a small current flows into the Base and out through the Emitter, then the barrier effect is reduced by a large amount and a current starts flowing from the Collector to the Emitter:



The ratio of the base current to the Collector current which it triggers is called the DC power gain. For example, if one milliamp of current flows into the base and causes a current flow through the transistor of 30 milliamps, then the gain is said to be 30, and that is about the gain which we can expect from a TIP3055 transistor.

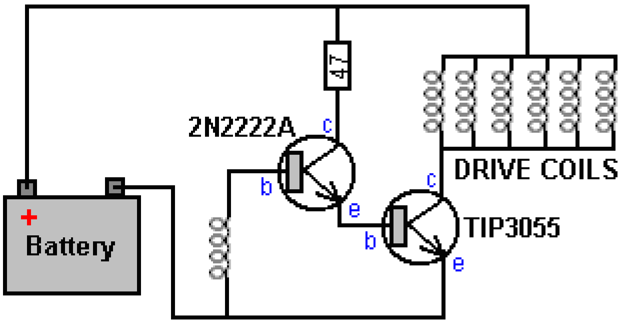
That is not a very high gain and it would be nice if it were much higher. We can arrange that increase in gain by using one other transistor – a low power transistor which has a high gain of about 200, say, a BC109C or a 2N2222A transistor. If we use one of those to amplify the current going into the base of the TIP3055, then the overall gain becomes 200 x 30 which is six thousand. A gain of 6000 should work very nicely for our generator.

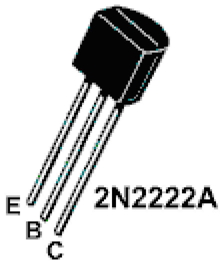
The way that we use the transistors is we have one coil act as a synchronisation or timing sensor. It detects a rotor magnet passing by because the magnet generates a voltage in the coil and we use that voltage to switch on our pair of transistors:



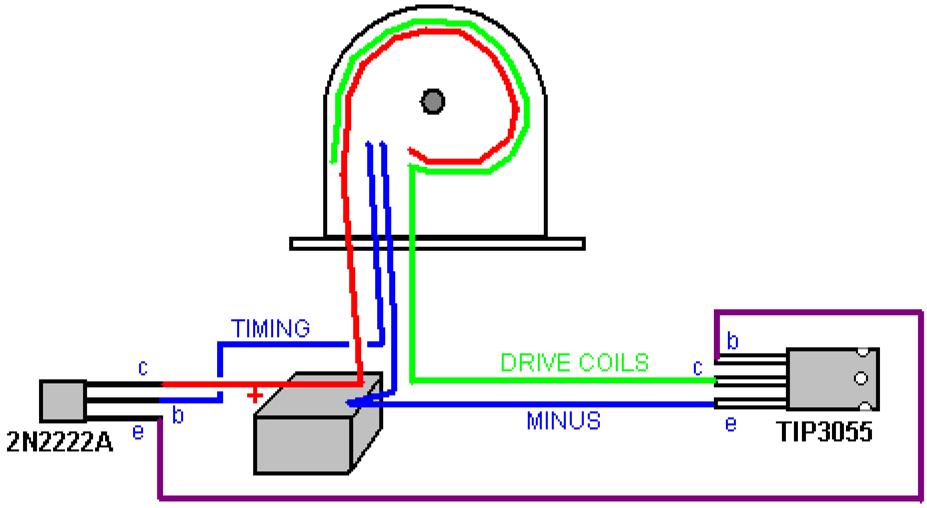
This works as follows. When the rotor magnet passes the timing coil, it generates a voltage in that coil. Each transistor needs about 0.7 volts to switch on, so if the voltage generated in the timing coil exceeds 1.4 volts (which is pretty certain for a coil with many turns in it) then that voltage will cause a current to flow through the Base of the small transistor. That turns the small transistor On, feeding a generous current into the base of the big transistor through the 47 ohm resistor which limits the size of that current, turning the TIP3055 transistor On and causing a large current to flow through it.

If we connect the generator's drive coils between the collector of the large transistor and the battery Plus terminal, then that big current will flow through those coils, powering the rotor on its way. By adjusting the position of the Timing Coil, we can control exactly when the drive coils get powered up, and so we can adjust the position to get the very best performance from the generator. The circuit diagram for this is:



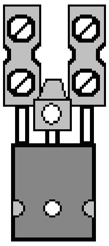


Physically, that is:

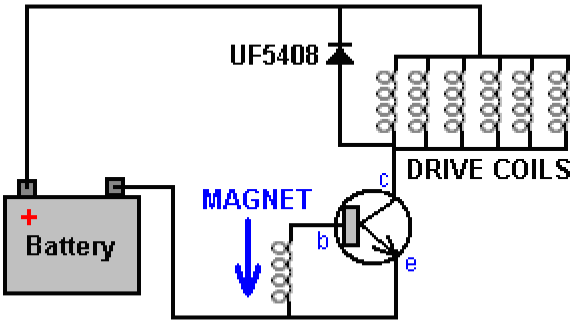


Here, the red positive connection to the battery goes to the Collector of the 2N2222A transistor and to one side of all of the drive coils. The green wire connects to the other side of all of the drive coil connections and on to the Collector of the TIP3055 transistor. The Minus of the battery goes to the Emitter of the TIP3055 and to one side of the single timing coil and the other side of the timing coil goes to the Base of the 2N2222A transistor.

If you don't want to solder connections to transistors, then you can bend the centre leg upwards and use individual, trimmed down screw terminals, one on each leg:



I suggest that initially, you ignore the power take off circuitry and concentrate on getting the rotor spinning satisfactorily. However, just before starting on that, consider the first circuit diagram shown and consider the difference:

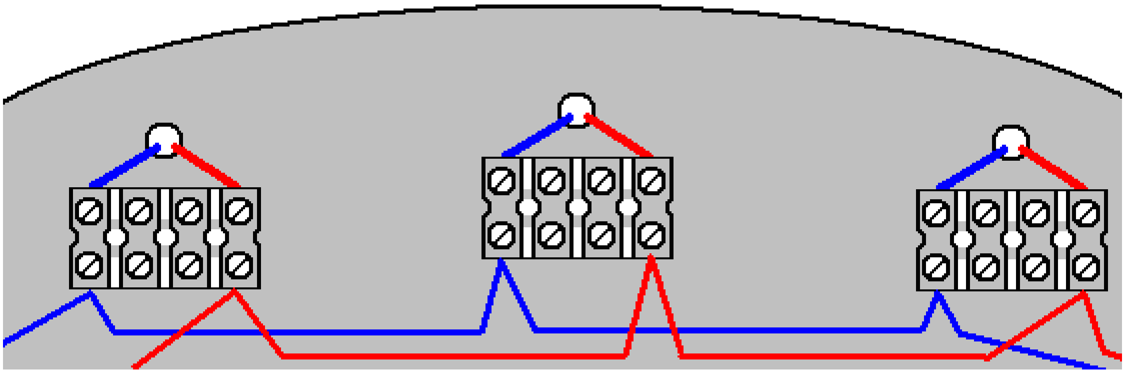


You will notice that there is a diode between connected across the drive coils. The direction of the diode will not allow current to flow from the battery through it (it would have to be connected the other way round if we wanted that to happen – which we don't). A feature of coils, especially coils with lots of turns, is that if they have a current flowing through them, they really, really don't like that current flow to be stopped. If it is, then they generate a large voltage spike in the reverse direction.

If the battery is a 12-volt battery and the transistor is switched hard On, that connects the full battery voltage across the coils and so causes strong current flow through the coils. When the transistor switches Off it stops the current flow through the coils, which promptly generates a major reverse voltage in the coils. Because one side of the coils is connected to the battery Plus, that voltage drags the collector of the transistor to a much higher voltage than the voltage of the battery. This worries circuit designers as the transistor might not be able to survive such a high voltage, and so they connect a diode from the battery Plus to the transistor Collector. The thinking behind this is that once the transistor Collector is dragged to 0.7 volts or more, above the battery voltage, then the diode will start to conduct and that will collapse the voltage spike of the coils and prevent the voltage getting much above the battery voltage.

That does happen, and yes, it does protect the transistor from being damaged by excessive voltage. But, consider the current flow through the diode. It is connected to the battery Plus, and so any current flows back into the battery as it has no alternative flow path. That recovers some of the current used to drive the generator, so the diode is much more useful than just protecting the transistor (especially since we could use a transistor able to withstand the high voltage generated). Please note that the diode is a UF5408. The "UF" stands for Ultra Fast, meaning that the diode is able to switch On and Off very quickly indeed. That is important when we are dealing with very fast, very sharp voltage spikes like those generated by our coils, so please don't assume that any old diode will do the job for us, as we need a fast one.

Just before we leave the drive coils to move on to the power gathering coils, let me confirm how they are connected. Initially, we need the biggest possible push from the coils and so they are connected 'in parallel'. That is, like this:



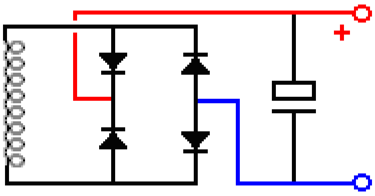
The start of each drive coil is connected to the start of every other drive coil (the blue line) and the end of each drive coil is connected to the end of every other drive coil (the red line). The TIP3055 power transistor applies the full battery voltage to all drive coils simultaneously. Initially, I would suggest that you try ten drive coils as that was what suited the original build, although it is highly unlikely that those coils are the same as your coils.

To get the rotor started requires giving it a push in the right direction. That will start the pulsing drive pushing the rotor around and it will accelerate to its working speed all on its own. Some people may feel that the rotor could rotate in either direction. That would be the case if, and only if, the timing coil is positioned centrally without any movement when the wheel performance is optimised after the power collection coils have been wired up and are contributing output power. So, choose a direction of rotation and stay with it at all times.

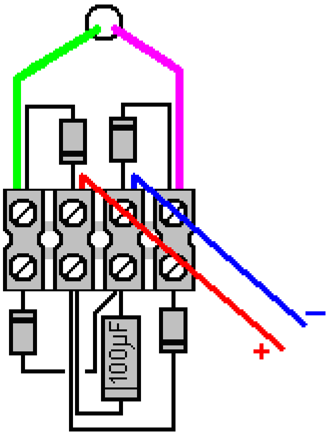
When a magnet passes close to a coil of wire, the result is a voltage between the ends of the coil. That voltage varies with time and is generally a sine wave shape which varies slowly compared to the voltage spikes of the rotor-powering coils when they are switched Off, and so, any diode can be used to convert that voltage to Direct Current.

Ideally, you have 3000-turn coils mounted on the second side of the fifteen active planks (the sixteenth plank being exclusively for timing and adjusting for the best possible performance, certainly on the first rotor, any additional rotors don't need a timing coil as we already have that). For the moment, leave the remaining five rotor-powering coils unused as we can decide later if they are to be powering coils or power-gathering coils. We won't know that for sure until we start drawing current from the generator, because that current flowing in the output coils causes a magnetic field which alters conditions for the rotor. So, we need to see how it goes when we are drawing current from the generator.

I suggest that every power output coil is treated exactly the same as all of the other power gathering coils. First, we use four diodes to convert all of the coil power from AC to DC. This is done with a standard bridge configuration like this:



This arrangement may look a little strange. The four diodes are not a bridge although electronically they do form one. These can be four separate, discrete diodes such as the 1N4148 or the 1N4007 both of which are incredibly cheap as they are so popular. Alternatively, a 1.5 amp 100V single-package diode bridge can be used nearly as cheaply. The capacitor shown is very helpful for testing as well as for producing a good output. It can be quite small in value, perhaps 100 microfarads or 1000 microfarads if you prefer. It is easier to check the output voltage on each power gathering coil when there is a capacitor in place, and you get an increased capacity smoothing capacitor with every output coil added. A possible physical layout is:

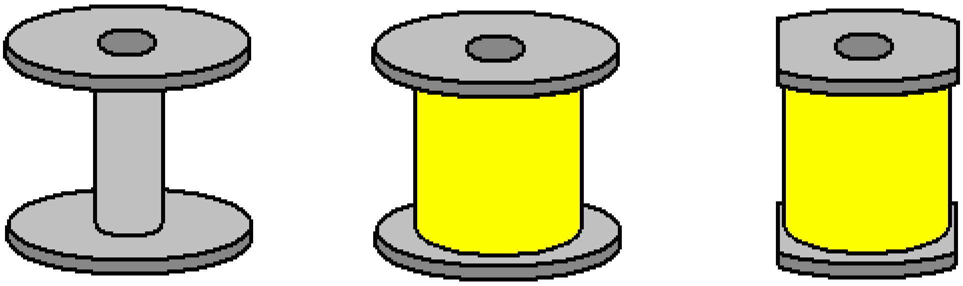


The original build was to show conclusively that the generated output power was greater than the input power. That was the reason for all of the meters used on the original. As the input power was DC and the output power was DC, measuring the input voltage and current gave the input power, while measuring the output voltage and current gave the output power and the demonstrations showed that the output power was more than three times larger than the input power.

That being the case, we should be able to get the generator running and then switch from battery input to feeding the input from a capacitor powered by several of the output coils. This type of rotor drive is really good for doing this, because the drive voltage is not particularly important. I can see no reason why this generator cannot be self-powered and still supply power for other uses. With three rotors, many magnets and many coils, it should be possible to extract significant power from this generator. Even if that were not the case, there are various devices in chapter 14 ("renewable energy systems") which need very little power to be useful – lighting, cooling, etc.

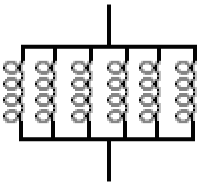
One really big advantage of this design is that it is easy to understand, easy to expand, and does not need any specialist skills. Also, while a number of hand tools have been used in the construction, if you do not already own those tools you don't necessarily have to buy them. It is likely that a friend has them and can lend them to you or alternatively, a local hire shop can rent you those tools for a day or even half a day at a very low charge.

If you prefer not to make coil spools for yourself, then it is possible to buy the wire on a large number of 50-gram reels. The reels supplied by the Scientific Wire Company are good quality plastic, 40 mm diameter, 30 mm tall, with 2 mm thick flanges, which leaves a shaft length of 26 mm. You can wind the wire off one spool on to any suitable temporary holder, giving you one empty spool. That spool can then be wound from two of the full spools and that gives you two empty spools. Every spool wound, gives you an extra empty spool. As the 40 mm diameter flange is wider than we need, **after** the coil has been wound, the excess flange width can be cut off with your coping saw:

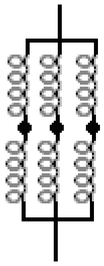


The hole through the shaft of the spool is 10 mm in diameter but that is no problem as the 6 mm diameter threaded rod of your winder can easily be expanded to 10 mm by wrapping a length of masking tape, duct tape, electrical insulating tape or any other similar tape, around the shaft to align the spool which is then clamped in place by the nuts and washers.

If your particular build of this generator produces a voltage which is lower than you want, then instead of connecting the output coils in parallel you can start by connecting them in pairs before making the parallel connections:



"in parallel"

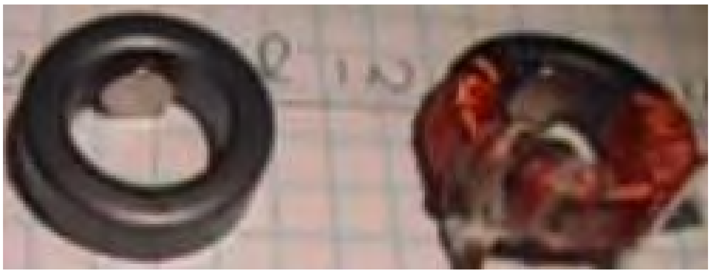


Twice the voltage but
half the current

The second arrangement is called connected "in series parallel" and naturally, as they are only half the number of pairs of coils as there are single coils, the overall current is only half of what it is when the coils are connected in parallel. However, the power is exactly the same no matter how the coils are wired together.

To tune the generator for best output, you can connect a voltmeter (usually a multimeter set to it's 20-volt DC range) across any output coil's capacitor and move the timing coil slowly to find the position of the timing coil which gives the greatest output. That is why it is probably best to have the timing coil on the top plank where it is easiest to get at.

There are a couple of additional things which you may care to try out to see if they work well. They both are a different style of drive coil. The first comes from what is known as the Thomas Motor as shown in the video https://www.youtube.com/watch?v=9s7sM3csFHM&feature=youtu.be. This drive is a strong but small permanent magnet which is placed inside a wire wrapped ferrite toroid. When the toroid winding is energised by passing a current through it, the resulting magnetic field circling around the toroid blocks off the field of the permanent magnet, acting as a very effective magnetic shield:



The toroid used is probably the 22.5 x 13.5 x 10 mm toroid from China, currently selling at £5.01 for a pack of ten toroids delivered from China:

The above video has some errors in it so please use common sense and use the technique rather than paying undue attention to what is said.

The toroid is wound with one continuous helical counter-clockwise coil going all the way around the core. The one shown is wound with approximately 10 metres of 38 gauge enamelled copper wire which has a diameter of 0.15 mm. The permanent magnet used is 6 mm diameter and 3 mm thick. If the rotor magnets have the North pole facing the coils, then the North pole of the magnet inside the toroid, faces the rotor and the coil is energised until the rotor magnet has just passed and then the current is cut off to allow the toroid magnet to push the rotor on its way through repulsion.

The second method is using the Steorn 'Orbo' style coils (with no toroid magnets). These toroids are also wound in the same way using ferrite toroids as shown here: https://www.youtube.com/watch?v=aCpniBm9i_M and described in chapter 1. With no current flowing through the winding, the rotor magnets are attracted towards the ferrite toroids. When the rotor magnets align with the toroids, the current is switched on, blocking the ferrite toroid from the rotor magnets and letting the momentum of the rotor carry the rotor magnets half way towards the next toroid, where the current is cut off and the attraction starts all over again. For best effect, the hole in the centre of the toroids faces towards the rotor and not as shown in the above video. This technique of letting the rotor magnets provide the power which spins the rotor is the method used by Robert Adams in his COP=8 motor generators shown in chapter 2.

If you are confused by the many possible options for making a generator of this general type, then I would suggest that you choose to have just one rotor with sixteen magnets on it, and 31 coils each with 3000 bi-filar wound turns (that is, one coil on both sides of each plank except for the timing coil plank).

If you choose to construct this generator, then good luck with your project. Remember that increased power comes with more coils, more rotors, more coil turns. I would expect you to have a lot of fun adjusting and optimising this generator.

Chapter 18: Avoiding Lenz's Law

As you are probably aware, commercial transformers and commercially available electric motors are wound in a symmetrical way which forces them to oppose their own function – a bit like getting a push start with a car whose battery is depleted, **but**, having two people at the front pushing backwards and two people at the back pushing forwards. That is so stupid that it is difficult to believe that anyone would do it, but that is exactly how motors and transformers are 'designed' and built. The bigger the output power, the more the output power opposes the input power, meaning that you have to have greater and greater input power in order to get greater output. That is what Lenz's Law is all about.

It doesn't have to be that way. If you build a non-symmetrical transformer like Thane Heins has done, that effect is absent and the output power can be forty times greater than the input power as shown by bench test results. It is not all that easy to build a completely non-symmetrical transformer or motor, but there are other ways to approach the problem. Vladimir Utkin has produced the following presentation explaining the ins and outs of an alternative way of dealing with the problem. Some readers may well find it a bit technical in the later stages, but the initial information can be understood by anybody.

Introduction

It's well known, that orthogonal coils, that is, coils at right angles to each other, do not interact. This is illustrated in Fig.1. In the following diagrams, the letter "U" represents voltage, the letter "I" represents current and L stands for a coil of wire:

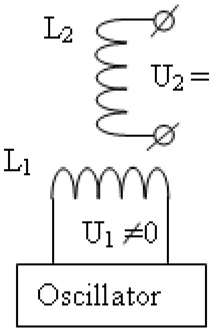

Fig.1 These orthogonal coils do not interact.

This means that when there is an oscillating voltage applied to the input coil L1, there is absolutely no voltage induced in the coil L2. It makes no difference if the coils are air-core or if they have an iron core. In other words, it can be assumed that the coils are suspended isolated in air.

This is a well-known fact but it is considered to be of little interest as it is thought to be a trivial matter – it isn't. If we can make the coils L_1 and L_2 interact so that real power can be extracted from coil L2 without that extracted power effecting the input coil L1, then that is a very different matter and nobody would dismiss that as being "trivial" !!

That very desirable situation can indeed be brought about as shown in Fig.2, by adding two permanent magnets, M1 and M2, facing each other on the axis of the coil L1, and switch from powering coil L1 with voltage to powering it with current, and for that, we add the capacitor C and operate coil L1 in resonance where the real magnetic field is in the ambient space. Here, the input current is at a minimum and the magnetic output is at its maximum. We add a load to coil L2 as it is now able to provide output current:

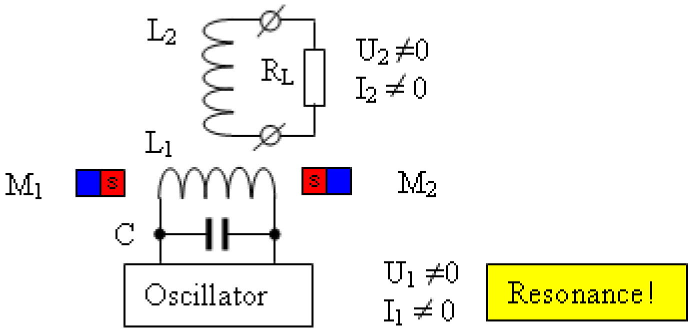

Fig.2 Orthogonal coils interact with broken symmetry.

In Fig.2 the South poles of the magnets face each other, but the arrangement also works if it altered so that the North poles face each other. I suggest that the problem is solved, that is, the load R_L receives real power, which has no bearing on the resonance of the input circuit. I will now try to explain how and why this configuration solves the feedback problem.

The main explanation

In Fig. 1, when two magnets (M1 and M2), are added as shown with the same poles facing each other along the axis of the coil L1, this adds a magnetic field which flows perpendicular to the axis of coil L1, and encompasses some, or all, of coil L2. This changes everything, because the magnetic fluctuations in coil L1 can modify the magnetic field produced by the magnets and causes induced voltage and current in coil L2.

For this, we made the "moving" magnetic field by adding alternating current to the coil L1, resulting in alternating magnetic flux passing through coil L2. Current and voltage are induced in the output coil L_2. This is shown in the slightly simplified illustration Fig. 3, indicating the movement of the magnetic field depending on whether or not the oscillator powering coil L1 augments or opposes the magnetic field produced by the permanent magnets.

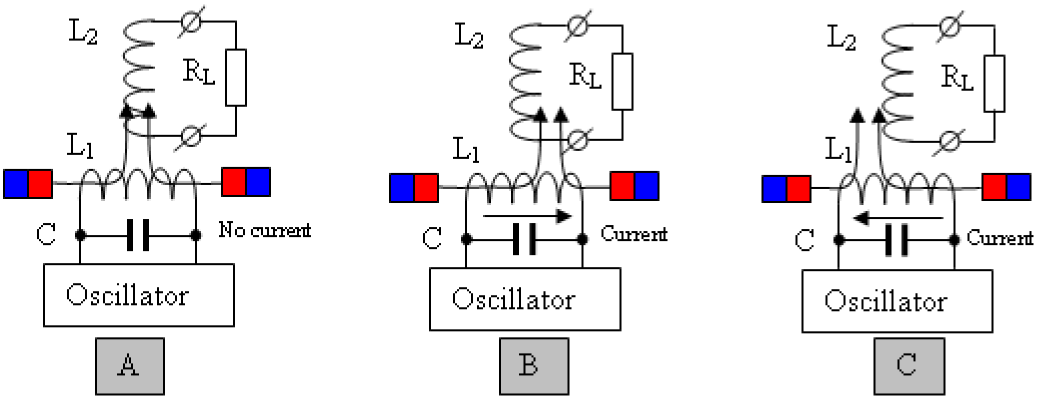

Fig. 3. Principle explanation of the asymmetrical interaction of the orthogonal coils due to the movement of the field.

The resonance coil L1 is used to create an oscillating magnetic field, but that "moving" field can also be created using permanent magnets, introducing them into the gap between two oppositely facing magnets through the physical movement of those extra magnets as shown in Fig. 4. The moving magnets would be on a rotor and the poles of the rotor magnets would alternate N, S, N, S…

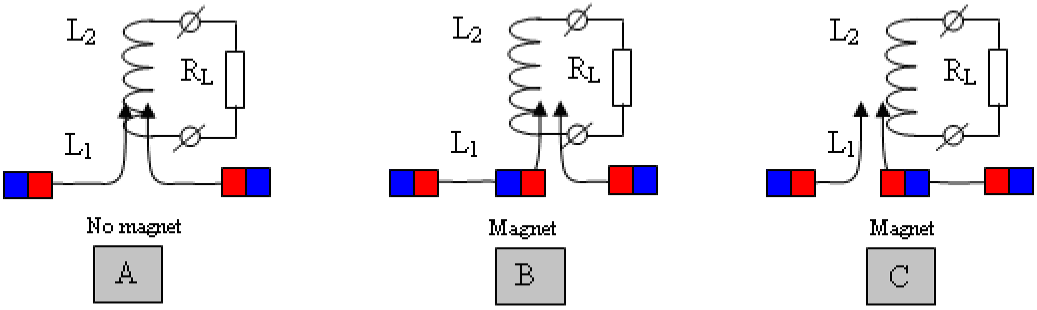

Fig. 4. Explanation of the principle through the use of permanent magnets.

Possible errors in interpretation

The following errors are possible in the interpretation of the described interactions:

1. Harnessing resonant energy to the load.
2. Harnessing the magnetic field energy to the load.

Neither interpretation is true. The basic principle shows that the energy of any resonant system cannot "be tapped" because doing that would destroy the resonance itself. Also, the energy of the magnetic field is not used, because the magnetisation of the magnets is not changed or reduced in any way.

The most reasonable interpretation is from the position of double energy systems; within which, due to internal organisation, some latent energy is induced - and then fed to the load. From the point of view an outside observer (the oscillator), this energy is imaginary, but in terms of an internal observer (the output coil) it is quite real. Monitoring the energy in different coordinate systems produces different results, which conform to the current scientific knowledge.

The Law of Conservation of Energy

The 1918 theorem of the mathematician Emma Noether states, that each continuous symmetry of a physical system corresponds a conservation law:

Symmetries of time corresponds to the law of conservation of energy,
Symmetries of space corresponds to the law of conservation of momentum,
Isotropy of space corresponds to the law of conservation of angular momentum,
Gauge symmetry corresponds to the law of conservation of electric charge, and so on.

That is, the symmetry exists in Nature, and then that leads to the corresponding Conservation Law theory. At the same time, all the symmetries are seen as "immutable". The possibility of breaking any symmetry is not even considered, although doing that does not actually contradict anything, it merely changes the physics.

Thus, the Law of Conservation of Energy actually cannot be violated as a principle, because that “Law” is the **result** of an existing symmetrical interaction and not the **cause** of that symmetrical interaction. However, to bypass the applicability of the Law of Conservation of Energy is perfectly possible. To do that, all that is needed is to arrange things in such a way that it breaks the symmetry. The method described above is an asymmetrical interaction, and Emma Noether's theorem just does not apply (but, that needs to be proved at a future date).

The dependence of the output power

The output power depends on several parameters:

1. First of all, it depends on the intensity of the initial magnetic field of the permanent magnets, which is to be "moved". The greater the intensity of that magnetic field, the higher the output power will be. A zero intensity magnetic field produces zero output.

2. Secondly, it depends on the distance through which the initial magnetic field shifts, that is, from the current in the resonant coil (or more accurately, on the reactive power caused by that current flow).

3. Thirdly, it depends on the speed of "movement" of the initial magnetic field, that is, from the resonant frequency. The higher the frequency, the higher the output power will be, because the EMF output coil depends on the speed of changes in the initial magnetic field.

This last point suggests the decrease of resonant circuit capacitance, when the voltage on it is raised (for preservation of the stored energy in the circuit). This should lead to increased output power.

Replacing the permanent magnets with electromagnets

Replacement of permanent magnets by electromagnets is obvious and may be done for various reasons. For example, it could be due to lack of the necessary permanent magnets, or alternatively, due to the fact that magnets become gradually demagnetised due to the influence of "moving field" of L1 coil. Anyway, the substitution of electromagnets can definitely be done. We do this for the generalisation of the principle, because later we will show that electromagnets were used in some ‘prior art’ devices. In this case the electromagnets can be included either sequentially or in parallel, the polarity of voltage applied to them can also be selected arbitrarily.

One such modification is shown in Fig, 5 for (A) sequential and (B) parallel electromagnets.

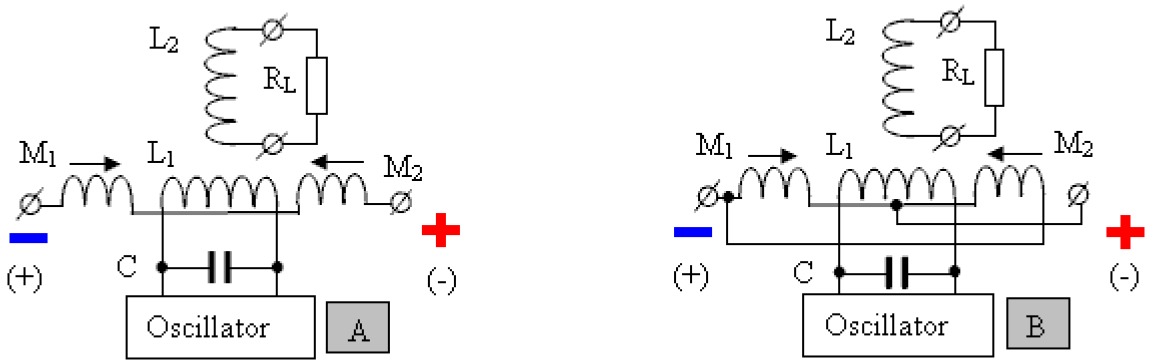

Fig. 5. Replacing the permanent magnets by electromagnets with (A) serial and (B) parallel connection.

Here, for parallel connection of the pair of electromagnets, it can actually be represented as one short-circuited coil, in which the resonant coil induces the voltage of the following distribution:

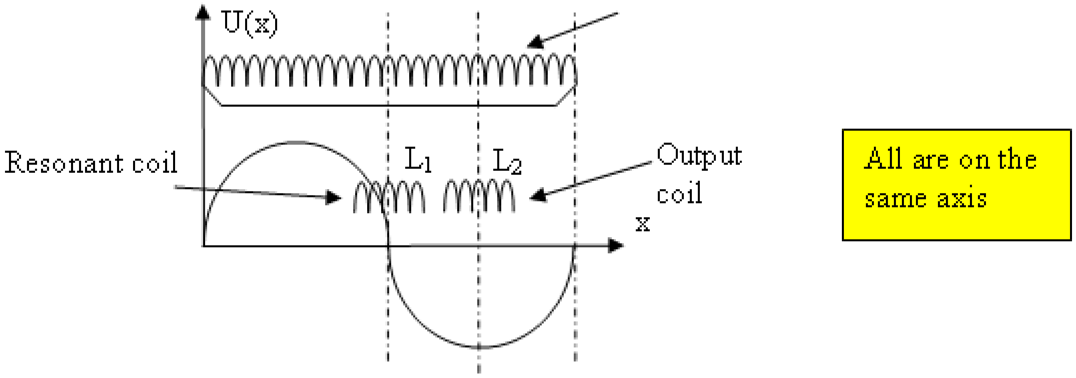

Fig. 6 The voltage induced resonant coil in electromagnets included in parallel.

This allows the output coil to be placed on the same axis as the resonant coil, because the resonant coil induces no voltage in the output coil without current in the electromagnets. In practice, this leads to the resonant coil being wound exactly halfway of the short-circuited, and the output coil in the correct position of the short-circuited coil.

Using the electro-radiant effect

Using the electro-radiant effect is an extension of the idea of using magnets when causing interaction between orthogonal coils. The purpose is the elimination of the master oscillator and power supply for the electromagnets. The easiest way to see the electro-radiant effect is with the spark discharge of a pre-charged capacitor, where at least one of its electrodes is an inductor.

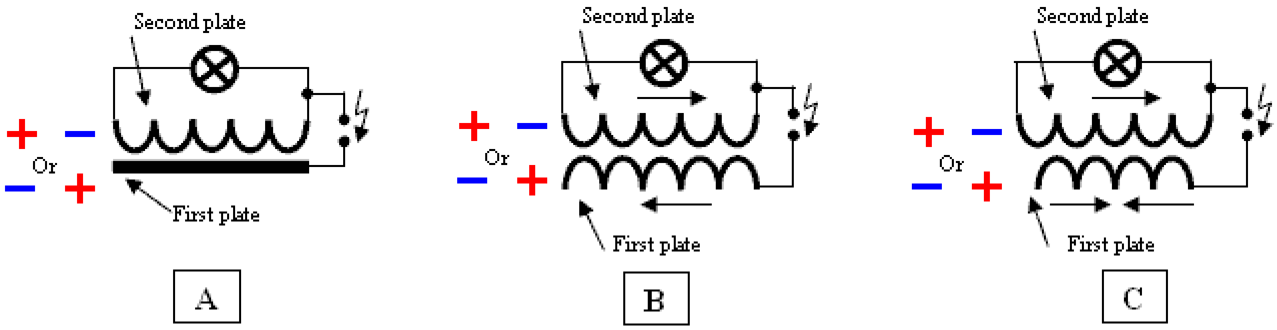

Fig. 7. The simplest manifestation of the electro-radiant effect (the light is on).

We are interested in option (B), in which one plate is fully wound in one direction and the other electrode is made in two halves wound in opposite directions. The electrode is wound in one direction, will be used as the resonant coil, and a plate of two halves as the windings of the solenoids.

The result of this modification is presented in Fig.8 for serial (A) and parallel (B) powering solenoids.
If the flow of sparks (turn-to-turn capacitance discharge) occurs with a frequency of the resonance circuit, it will lead to the maintenance of sustained oscillations in the coil circuit. What you need to "move" the magnetic field. And the solenoids (electromagnets) would be to create a current, necessary to ensure initial fields that you want to "move". Thus, a separate generator for resonance and a separate source of current for the solenoids is not required. The spark will be weak, since it does not commute any high current circuits.

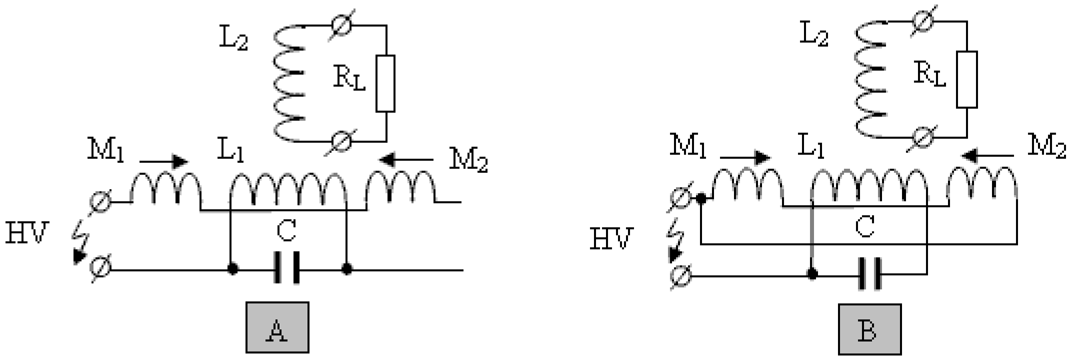

Fig. 8. The use of the electro-radiant effect to maintain the resonance and create a current in the solenoids (electromagnets) in their sequential (A) and parallel (B) arrangements.

Powerful magnet - resonance frequency of zero

This approach is a continuation of the ideas of solenoids and electric-radiant effect. Electro - Under floor heating effect is allowed to get rid of the generator and a separate power supply for the solenoids, to create a powerful alternating magnetic field to move the resonant coil (with appropriate spark supply frequency). However, the initial magnetic field in the solenoids can be quite weak. To strengthen it, and create a powerful permanent magnet used the idea of "resonance at zero frequency" or current accumulation – Fig. 8 (A).

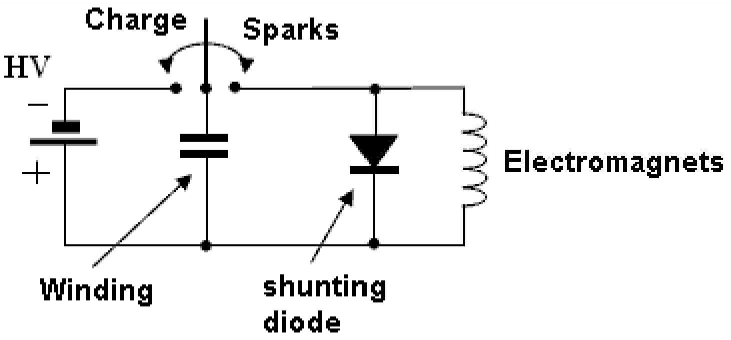

Fig. 8(A) Illustration of the idea of "zero resonance frequency" or the current accumulation..

This idea is quite simple and consists in the discharge inter-turn capacitance diode in the shunt solenoids - Fig. 8 (A). The diode is used to maintain the current in the solenoids between discharges inter-turn capacitance. Each discharge inter-turn capacitance, the current in the solenoids is increased (in accordance with the energy conservation law), and increases the power output of the entire device. The increase in current (and power) will occur as long as the losses in the solenoids are equal to the input energy due to discharge inter-turn capacitance.

Shunt switching circuits for accumulating current diodes, in serial (A) and a parallel connection of coils (B) are shown in Fig. 8 (B).

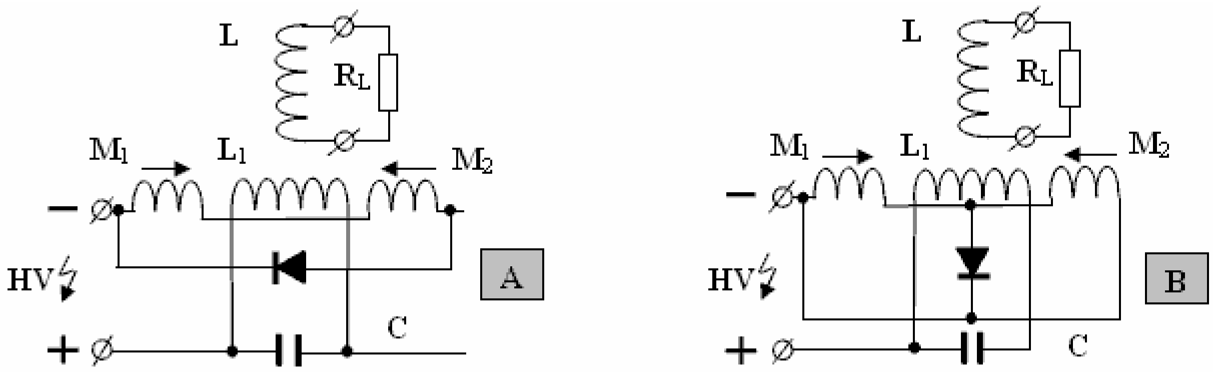

Fig. 8(B) Scheme incorporating bypass diodes to accumulate current, in serial (A) and the parallel connection of coils (B).

This approach allows you to "squeeze out" of the electro-radiant effect almost everything, that is, the coil - resonant, solenoids - powerful electromagnet.

ATTENTION: Schemes shunt solenoids for specific devices may vary slightly (e.g., by grounding the middle point coils).

Using the electromagnets as an output coil

This approach is a continuation for electromagnets ideas and the electro-radiant effect. It would be interesting not to use the output coil and use the electromagnets for it, thus ensuring the interaction of the two orthogonal coils. In this case, the creation of an initial field (for "moving") and harvesting output energy are achieved by the same circuit elements.

To do this, you need to arrange things so that the "moving" magnetic field "presses" differently for each of the electromagnets, leading to the formation in them of different currents. To this end, electromagnets which are connected in series can be shunted by capacitor, and connected in parallel with the electromagnets used but with a somewhat different number of turns. The resulting voltage distribution on the common electromagnet will be changed.

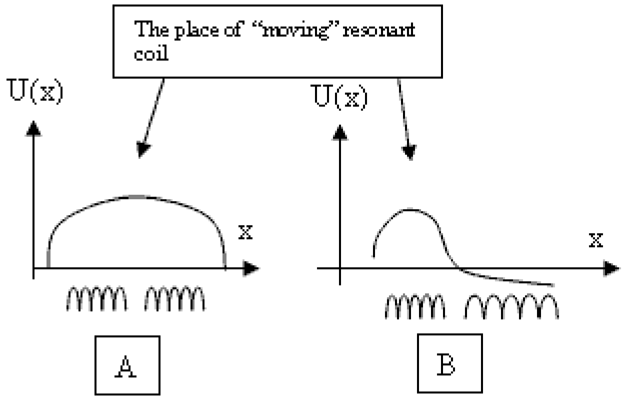

Fig.9 An ordinary voltage distribution on the electromagnets (A) and when they are used as an output coil (B).

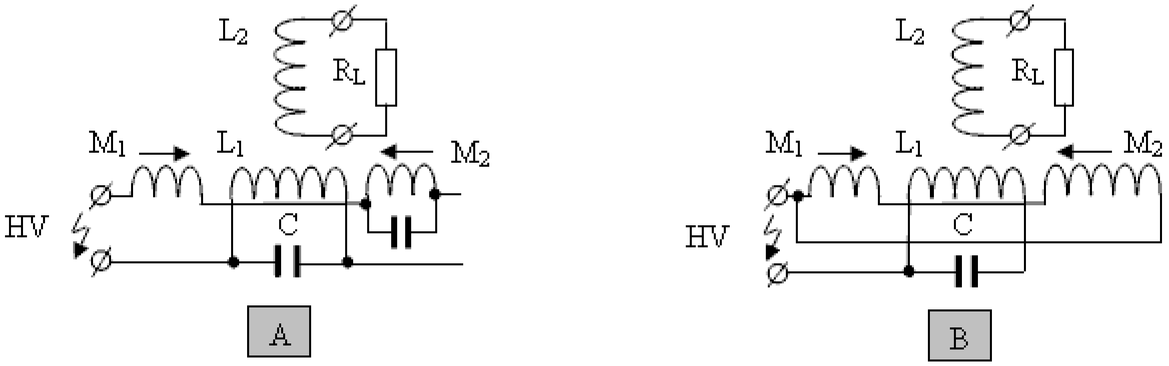

Fig. 10. Using asymmetrical electromagnets as an output coil.

But, the use of symmetrical electromagnets is also possible**.**

"Demagnetisation" - current amplification

"Demagnetisation" or "switching magnetic flux" is a kind of asymmetrical interaction for orthogonal coils. For the two coils to interact one needs to create an initial magnetic field.

The simplest implementation of the scheme "demagnetisation" is based on E-shape ferromagnetic cores and is as follows. The coil which creates the original magnetic field, is wound on top of the E - type core. The demagnetising coil is wound on core as usual as shown in Fig.10. In the absence of current in the outer coil and the absence of current in the inner coil, they do not interact - the output EMF on the external coil is zero - Fig.10 (A).

If there is a current in the outer coil, and a current supplied to the inner coil, the magnetic flux in the ferromagnetic core is trying to close the external magnetic flux on itself. An external magnetic field begins to "fade". As a result, the current in the outer coil is increasing to compensate the "disappearing" magnetic field – Fig. 10 (B).

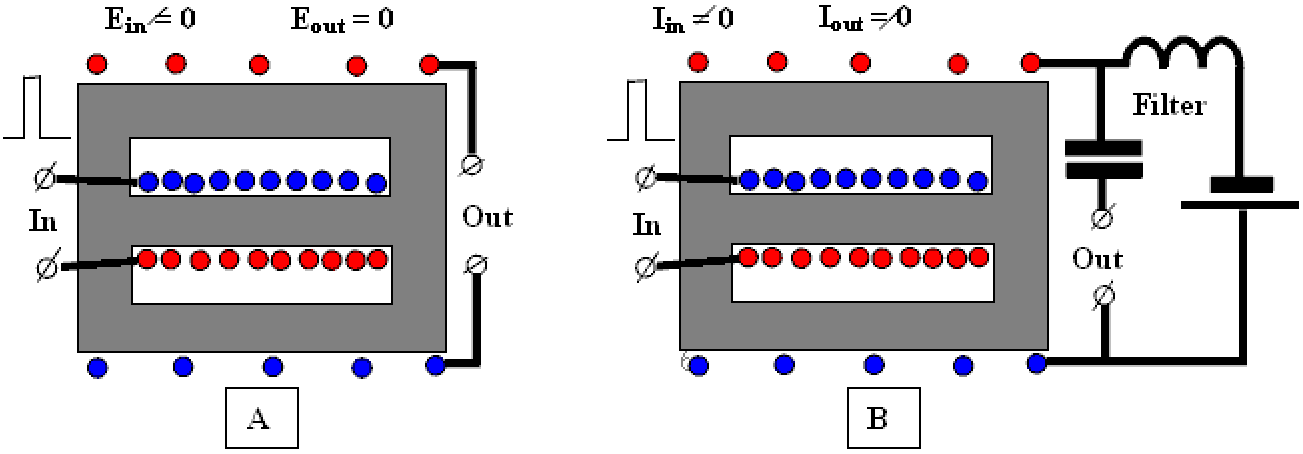

Fig. 11. A simple "demagnetisation" schematic based on E-shaped cores.

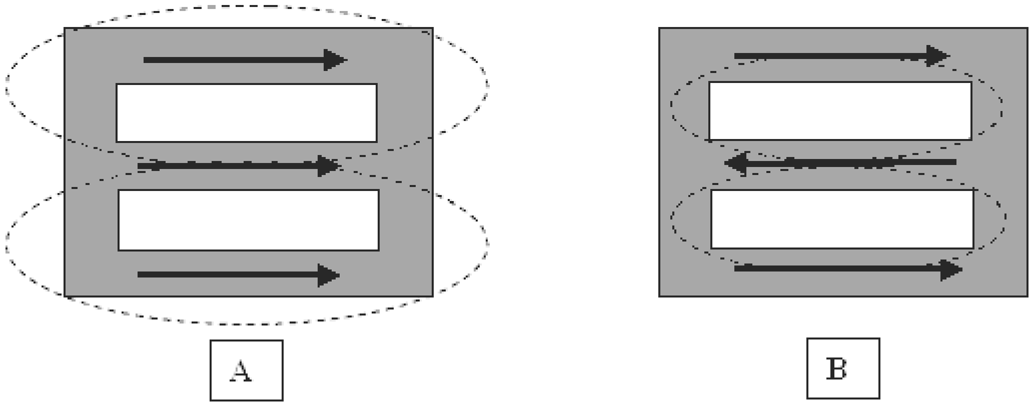

Fig. 12. The direction of the magnetic field inside the ferromagnetic core for magnetisation - (A) and demagnetisation - (B).

The output power depends on the same factors as mentioned earlier. There is no interaction without the initial magnetic field. Previously described interaction circuits without a divided output coil can also be considered a form of the principle of "demagnetisation" or current gain.

Already known schematics

The best known circuits are from Donald Smith's presentations and mainly his pdf document. His most simple circuit is comprised of a resonant coil and an output coil, and electromagnets are used in parallel connection instead of magnets. An electro-radiant effect is used for excitation.

CONCLUSIONS

The presence of the original magnetic field is an important factor in the devices of "free energy", based on the interaction of the orthogonal coils (an asymmetrical transformer). There is no interaction between the coils without the initial magnetic field. This initial magnetic field can be created either by permanent magnets or electromagnets (possibly involving the electro-radiant effect).

As a special case, this field can be created by the initial current in the output coil. Which leads to the schematic of "degaussing" ("shifting, moving") with increasing initial current. Here, a "moving, switching, demagnetisation" current is used as the resonant current needed by the input coil. In this regard, we can recall the words of Donald Smith, when he says that the magnetic field is the primary force in electromagnetism. The meaning of his words become clear, namely that without the initial magnetic field, there is no interaction between orthogonal coils.

The effect described here has been known for many decades and has been used by many "free energy" researchers to create their own devices. They were independently "inventing and reinventing" the effect. However, there is a reason to believe that the first time it was used was with Nikola Tesla's resonant transformer study (with spark excitation).

Also, given in the schematics, one could deliver other schematics and photographs of the various circuits and devices (both electrical and electromechanical), from a wide variety of authors, however, this work is not intended to be an encyclopaedia.

Instead, let us recall once again:

1. Energy conservation law is the result (not the reason) of symmetric interaction.
2. The easiest way to destroy the balanced interaction - to use an electromagnetic feedback in the field.
3. All asymmetrical systems are outside the area specified in the energy conservation law.
4. The Law of Conservation of Energy cannot be broken but it only applies to symmetrical interactions.

No private or state secrets are contained in this document which only uses open source material. Please note that all charts and diagrams are only provided as an aid to principles.

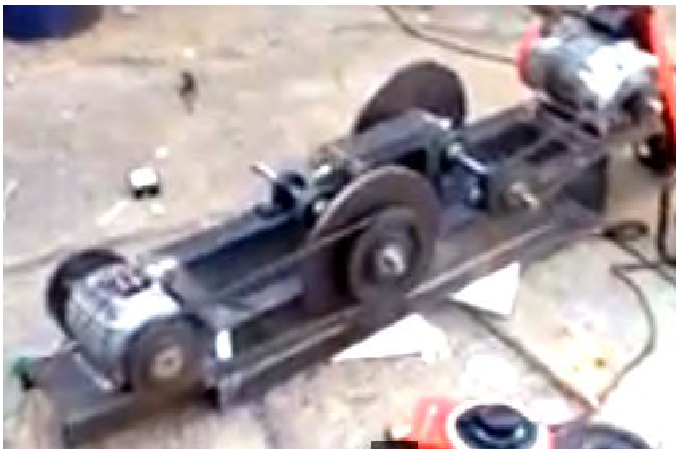
Chapter 19: Building A Motor / Generator.

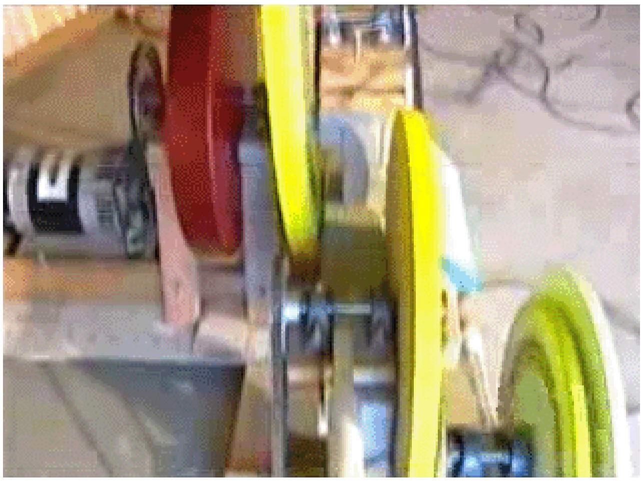
Using a motor-driven generator has been popular for a long time now. There are various types and styles and there is usually the desire to organise things so that the system is self-powered.

You have the simple, direct-coupled types where a second motor is used as a generator or a mains style of generator is used:

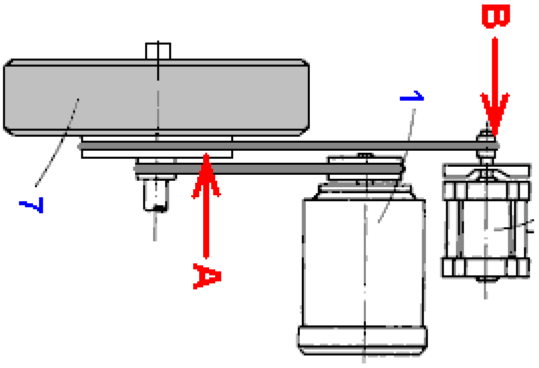


You will notice that two small flywheels are used in this system.

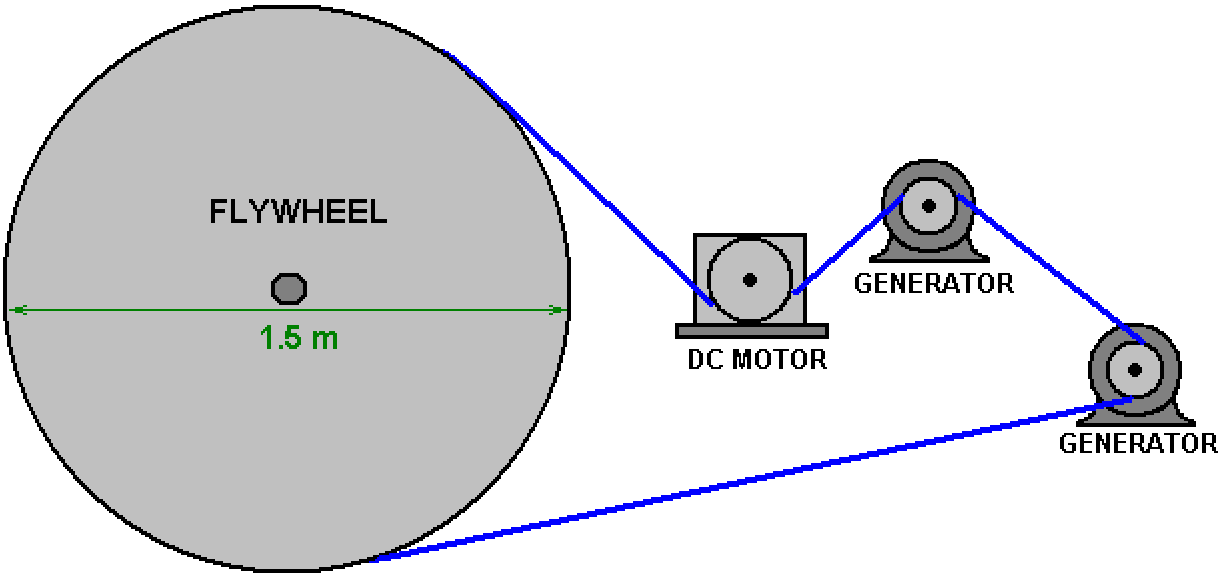
Then there is the style used by Chas Campbell of Australia where a large flywheel is used and pulleys allow for control of the speed of rotation as well as for alignment. Chas chooses to have his coupling spread out:



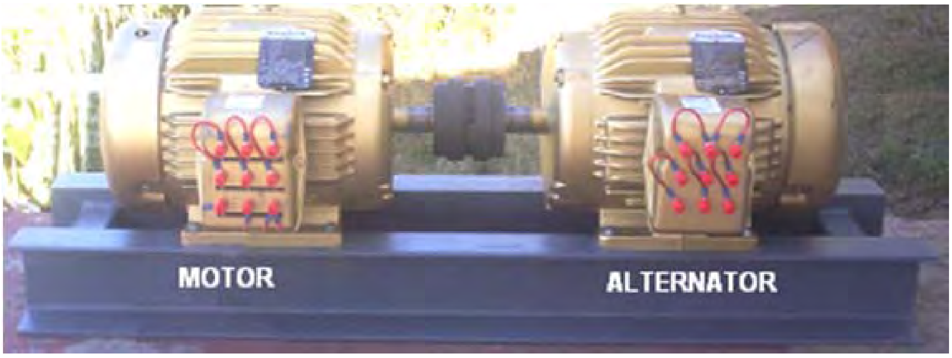
While José Luis García del Castillo prefers a more compact arrangement (which is presumably more difficult to construct and maintain:



And then there is the very rough and ready style used by “Mr Wilson” of Texas where he took an old round table and converted it into a very heavy wooden flywheel by hammering nails into the circumference to form a very rough V shape:



And then there is the most simple looking style where the motor is coupled directly to the generator, which in this case is a motor:



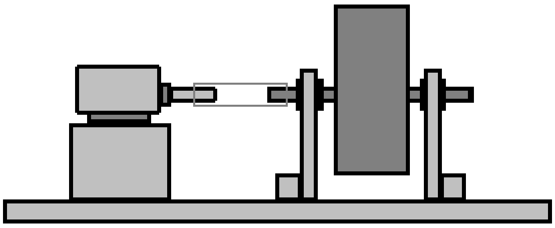
This last version is by far the most difficult to build as the shaft alignment has to be perfect and that requires:

1. The two shafts to be at exactly the same height.
2. The two shafts to be aligned exactly in the vertical plane.
3. The two shafts to be aligned exactly in the horizontal plane.

Achieving those three requirements simultaneously requires a skill level which I certainly don’t have. Please bear that in mind when we consider the next design which was built by John Bedini of America. John is an exceptionally talented and able developer. Unfortunately, his designs can look ever so simple but they are usually very subtle constructions as John is very intuitive and knowledgeable as well as being very persistent and patient. His designs usually need fine adjustments in order to achieve the remarkable performances which are routine for him. John never does anything without a reason and his initial build of a motor / generator, described by him in 1984 is dangerous because of the way that he chooses to use it and he states quite bluntly that using his technique can make the lead-acid battery explode. I do not recommend that you try to use John’s design in the way that he does as there is no need for involving a dangerous technique since a useful generator can be made and run perfectly safely.

I will try to explain John’s design and then go on to describe a simple version which most people would be able to understand, build and use safely. None of the drawings in this document are to scale and are included merely to aid understanding. It should be noted that John’s design has run quite literally, for years, keeping it’s own battery charged at all times. An American called Jim Wilson built an excessively large version of it and that produced twelve kilowatts of excess power as well as being self-powered. Ideally, we want to build something which is between those two sizes and which has a useful power output.

John’s design starts with a DC motor, which in the case of his first prototype is a General Electric permanent magnet, one-twelfth horsepower (62 watt) 12-volt motor which runs at 1100 rpm. That motor is coupled to a small, heavy flywheel:

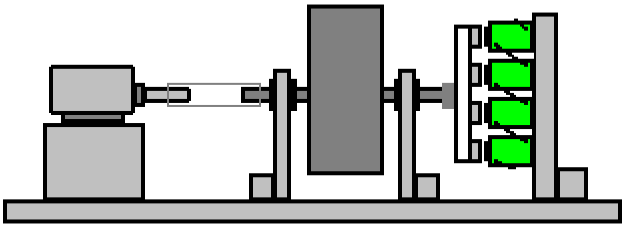


This coupling arrangement has the difficulty of aligning the motor shaft exactly with the flywheel shaft and a flexible coupling would generally be used by most people as it is very difficult to align the shafts perfectly.

The inclusion of the flywheel is said to be in order to keep the motor running well when it is being pulsed rather than having a continuous feed of electricity from the battery. Please understand that John knows far more about free energy than I do. However, I am not sure that I would agree with that assessment of John’s as the motor is designed to rotate 1100 times in a period of one minute and that is 18 times per second and it seems unlikely to me that the armature inside the motor would not have sufficient weight to run smoothly when receiving several pushes per second.

I think that a flywheel draws energy in from the local gravitational field (although I can’t prove that and wouldn’t care even if I could). Every particle making up the rim of the flywheel is accelerating inwards towards its axle and that happens continuously when it rotates. Anyway, either way, John has a great working system whatever the reason. In passing, John is so expert with lead-acid batteries that he has tuned his unit so that the battery does not realise that it is powering a motor and that creates a problem because the battery is getting recharged without getting discharged and so needs a protection circuit to prevent it getting overcharged. That is a nice problem to have.

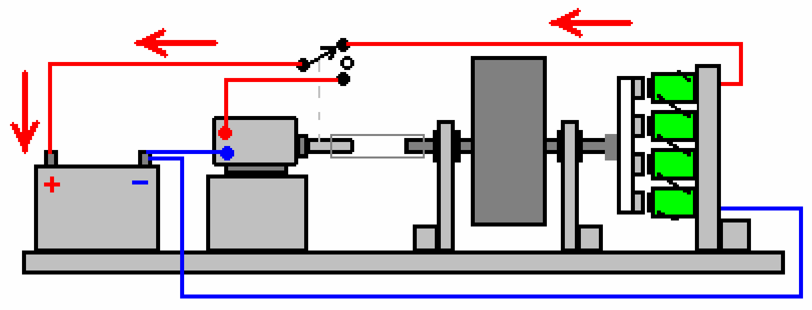
The rotating shaft turns a generator to produce a useful output. In the case of John’s prototype, he modified an American office 2-speed fan, using the housing for his own generator arrangement. The generator is a set of six permanent magnets spun in front of six coils of 200 turns each, of AWG 20 (21 SWG) wire of 0.81 mm diameter. The coils are connected in series, effectively making a 1200 turn coil which is pulsed by six separate magnets. Amazingly, the magnets are bonded to an aluminium disc. That seems strange as aluminium has major magnetic properties but the old phrase “if it ain’t broke, don’t fix it” applies and if you decide to attempt a direct replication of John’s generator, then do exactly what he does. The arrangement is like this, although only four of the six magnets can be seen as they are placed in a circle:



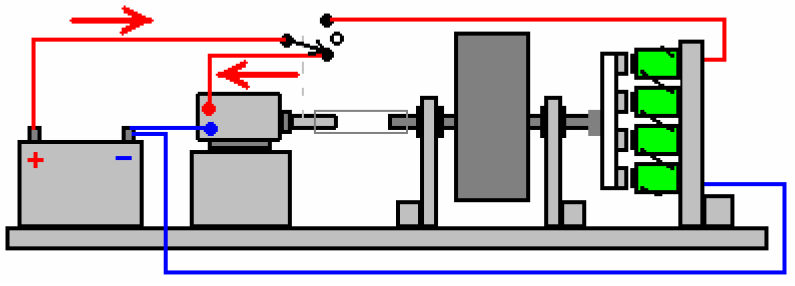
The coils have a metal core and Robert Adams stated that experimentation has shown that output coils should have a core whose cross-sectional area is four times the cross-sectional area of the rotor magnets. Robert also stated that the rotor magnets do not have to be exceptionally close when passing the coils and that a gap of 10 mm or so works well. This is an area where you can experiment to see what works best for your particular construction. John’s rotor construction is unusual as the North poles of the magnets bond to the aluminium disc and the South poles face the coils. I have seen the opinion expressed that North poles have four times the effect when passing power collection coils, that South poles have. But as always, if you are going to replicate something, then you do exactly the same, otherwise it is not a replication but instead is a notion of yours (quite possibly a notion that the inventor also had, tested, and found to be no use).

The next step for building this system is to arrange the connection of the output power from the generator. This is arranged to have the power going back to the battery for some of the time and for some of the remaining time the battery feeds power to the motor. This leaves me slightly puzzled. The output from the generator is available all of the time, but we seem to be abandoning it for half of the time and that doesn’t seem to make any kind of sense to me. With six output coils and six rotor magnets, each rotation feeds generator power to the battery while the six magnets pass three of the coils, but then, the generator output isn’t used while the magnets pass the next three of the six coils. Huh? Maybe I'm missing something here – perhaps that 180 degrees of unused rotation store extra energy in the coils or a capacitor which John does not show, but that seems unlikely to me. However, John only shows the system running itself and no indication at all of where any excess energy might be drawn from the system, although, presumably, a load could be powered directly from the battery which is powering the motor.

Anyway, the best switching arrangement for John has been to use a mechanical switch which acts as a single pole changeover switch mounted on the shaft of the motor (and electrically insulated from the shaft). First, the switch connects the battery Plus through to the Plus of the motor, causing it to rotate, as the battery Minus is permanently connected to the motor Minus. Current then flows from the battery, through the switch and into the motor (although John has his system so well tuned that he says that the battery supplies voltage but gets disconnected before any actual current has time to flow out of the battery). Then, just before 180 degrees of rotation have occurred, the switch opens and then connects the generator output through to the battery, with current flowing in the other direction through the switch. Timing in these systems is generally related to the position of the motor shaft and so each full turn is considered to be a timing of 360 degrees:

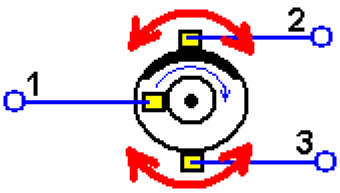


From 0 degrees to 100 degrees or less



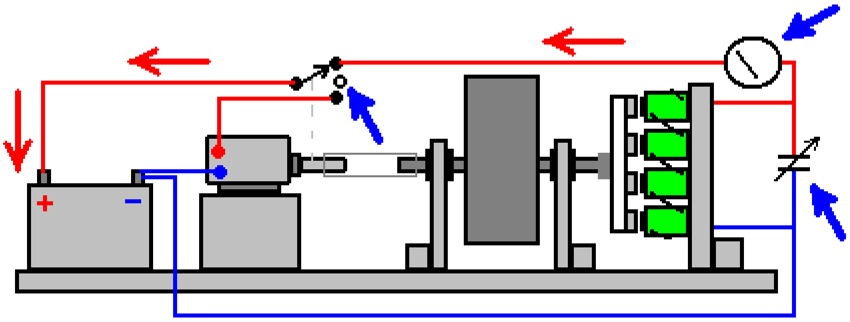
From 180 degrees to 280 degrees or less

For this switching, John uses this arrangement which is known as a commutator:



As the inner circle is electrically connected to the dark (copper) strip at the top which spans approximately 100 degrees around the circumference, sliding contact 1 is electrically connected to sliding contact 2 in the position shown above. When the disc rotates so that the copper strip no longer touches sliding contact 2, there is a period of about 80 degrees of rotation where there is no connection between any of the contacts. When the copper strip reaches sliding contact 3, then sliding contact 1 is connected to sliding contact 3. That arrangement is the equivalent of a single pole changeover switch. That switching system is mounted on the shaft of the motor but insulated from the motor shaft to avoid short circuits through the motor itself. However, contacts 2 and 3 shown above are adjustable in position so that the duration and timing of the pulses can be altered to some degree.

John says that he tunes his design by adjusting the feedback to resonate with the ions inside the battery. In my opinion that is highly dangerous and I would not for one moment suggest that you do anything remotely like that. That is why John recommends the use of protective clothing, eye shields and enclosing the battery in a very strong box to contain the acid if your fooling around with battery acid resonance strays into a danger area. It is not at all necessary to do what John does. How he does the adjustment is by putting a variable capacitor across the generator output and he adds a meter to show how his adjustments are affecting the operation, both when he alters the setting of the capacitor and when he alters the position of the commutator brush which feeds power back to the battery. The arrangement is like this:



So, to clarify the operation, the constructor is expected to adjust the variable capacitor and the duration and timing of the commutator switching on the motor shaft to get the exact combination which resonates with the acid in your particular battery. There is no indication of how these adjustments are best made or exactly what the meter would show when the optimum setting has been reached.

I personally do NOT recommend that you try to achieve battery acid resonance and I stress that if you choose to do so, then the results of your decision are yours and yours alone and nobody else is in any way responsible for what happens. If you succeed in replicating John's exact system, then congratulations to you, but please be very clear that I do not recommend it. Later on in this document I will be showing you a very effective and safe system for constructing a Motor - Generator system.

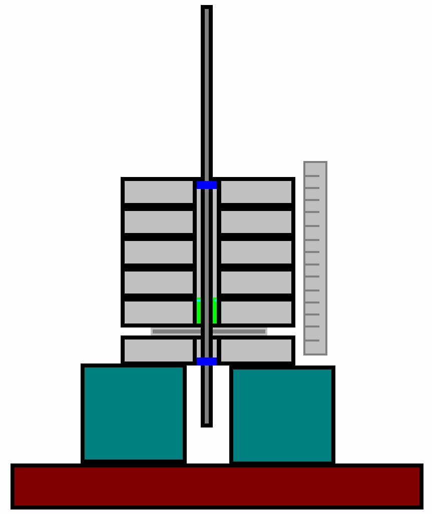
Alright, so far we have covered the general outline of a Motor - Generator system, from the most simple version using two motors with one being the 'generator' through to the very sophisticated Bedini design. We now have to choose which version is easiest for us to build and which will give us the greatest output power. However, let us consider some practical details.

I would suggest that we avoid trying to align shafts exactly and instead, use pulleys and belts as those are easier to align correctly as well as giving the ability to gear the speed of rotation up or down (although in John Bedini's case, the ratio is 1-to-1). In these days when 3D printers are becoming widespread, if you can't find the pulley you want, then a friend with a 3D printer can make one for you (3D printer maximum diameter is likely to be 220 mm). A friend who owns a lathe or alternatively a local steel fabrication company could also make any pulley wheel that you want. If those options are not possible for you, then you can actually make a pulley wheel by hand – a fact which in these days of automation, may not occur to you.

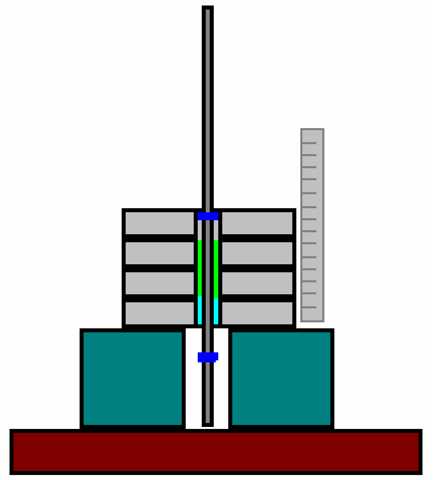
Making an accurate flywheel sounds difficult, but there are many things on the market which can be adapted to act as a flywheel. For example, dumbbells are low cost and very suitable:

These come with a mounting bar and clamps and using only half of the bar, can give 5, 10, 15 or 20 kilograms on the half shaft. It should also be possible to convert one of the smaller discs into a pulley if you feel like doing that. You can also get a flywheel made up by a local steel fabrication shop, or a friend with a metal-cutting lathe could make one for you.

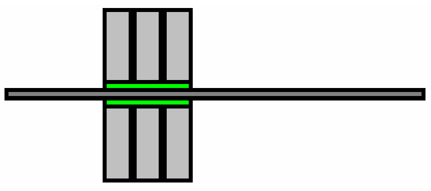
If you are inclined to put dumbbell discs on to a threaded steel rod or plain steel circular bar then the alignment can be helped by using a stack of the weights and some electrical tape. Decide where you want the first disc to be located on the bar. That is, what length of bar you want sticking out of the disc. The thickness of one disc further along the bar towards its end, wind electrical tape tightly around the bar and keep winding until the tape is a reasonably tight fit in the central hole of one of the discs and position a disc there. That places the rod central to the hole in the disc. Just above that disc put a piece of card which has a hole which is a tight fit on the rod and is wider than the hole in every direction. Measure all of the discs of that size which you have and measure along the bar to where the last disc would be if all those discs were placed in a stack on the bar. Wind more electrical tape to form a plug for the disc hole of the top disc in the stack. Supporting one disc on a pile of books or some other suitable packing which allows the axle shaft to be vertical, put one disc on top of the card on the rod and fill in around the shaft with epoxy resin. Then place all the other discs on the rod to form a perfect stack, using a straight edge all around the stack to ensure that the discs are exactly on top of each other. The electrical tape rings at top and bottom give exact alignment provided that the discs are all aligned exactly:



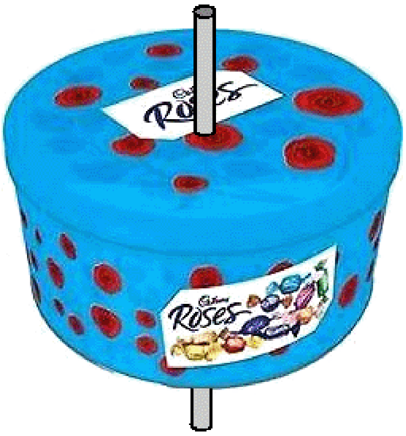
When the epoxy has gone hard, you can remove the upper discs and the bottom disc and remove the card which will be stuck to the epoxy and which will need to be cut away and sanded smooth. Treating the glued disc as the bottom one, as many discs as you want can be epoxied to the axle shaft in a single operation, ideally keeping an extra disc at the top centred with a ring of electrical insulation tape. Use slow setting epoxy and be sure to fill all of the gap between the axle shaft and the inside of the discs with no air voids in the epoxy and make sure that the stack of discs are exactly aligned, checking all around with your straight edge:



When the epoxy has set, you end up with an accurate, properly centred and squared flywheel:



If you are careful to get the centring and perpendicular angles right, it is possible to use a deep circular biscuit or sweets tin as a mould and with a central hole in both the bottom and the lid, fill the tin completely with a mortar mixture of sand, cement and water, using the lid to give you the exact alignment of the shaft which could be a threaded rod or a steel or brass bar:



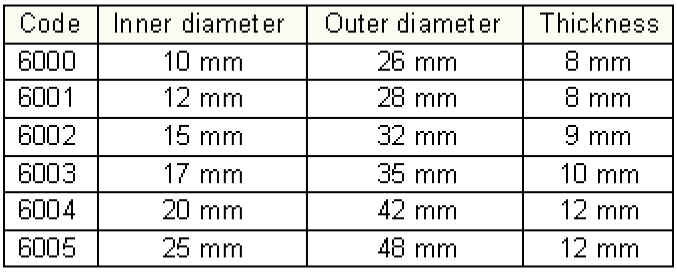
If using that method of construction, you might like to paint the tin if you are not keen on the manufacturer's decoration of the container. But, no matter what the flywheel looks like, the important thing is that it is balanced and aligned squarely so that when it is spun fast, there are no wobbles or wavering of the flywheel edge as that generates stress on the mountings. The flywheel axle should not be less than 10 mm diameter steel and anything up to 20 mm would be good. Consider the available pulleys and buy what you need before choosing the diameter of the axle.

http://www.beltingonline.com/vee-pulleys-273/spb-section-v-pulleys-682/1-groove-spb-pulley-699/?zenid=adem9c and others have a wide range of pulleys. Please remember that your drive motor will need a pulley which is made for a very different shaft diameter.

It would be nice to take advantage of the energy gain available from having different pulley diameters on the flywheel shaft and the generator shaft if that is possible, but if replicating John Bedini's design, keep the pulley ratios exactly the same.

As the flywheel is the biggest and heaviest thing in this construction, we start with it. We use a thick base board for mounting the various items, and we need powerful brackets to support the flywheel axle, which should be mounted in ball or roller bearings. We want the axle to be exactly horizontal so that there is no sideways force trying to push the axle through its bearings.

Common bearing sizes in Europe are:

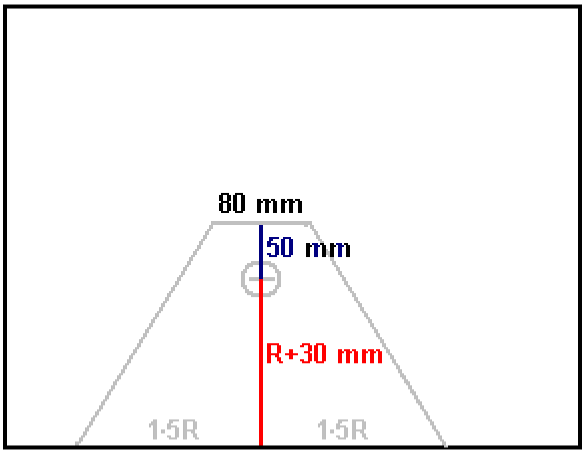


Code	Inner diameter	Outer diameter	Thickness
6000	10 mm	26 mm	8 mm
6001	12 mm	28 mm	8 mm
6002	15 mm	32 mm	9 mm
6003	17 mm	35 mm	10 mm
6004	20 mm	42 mm	12 mm
6005	25 mm	48 mm	12 mm

These bearings have a rubber seal to keep dust and dirt out of the grease packed around the ball bearings inside and that spoils the free movement. One way to overcome this has the bearing outer ring clamped stationary and an electric drill used to spin the inner ring until the movement becomes low-friction. An alternative method is to discard the rubber seals and remove the grease by immersing the bearing in paraffin (known as 'kerosene' in America). Then the ball bearings or rollers inside the bearing are lightly oiled to give a very free-running bearing. As our bearings are on an axle which is supporting a heavy flywheel spun by a motor, the bearings should wear in reasonably soon even if they are not made free running beforehand.

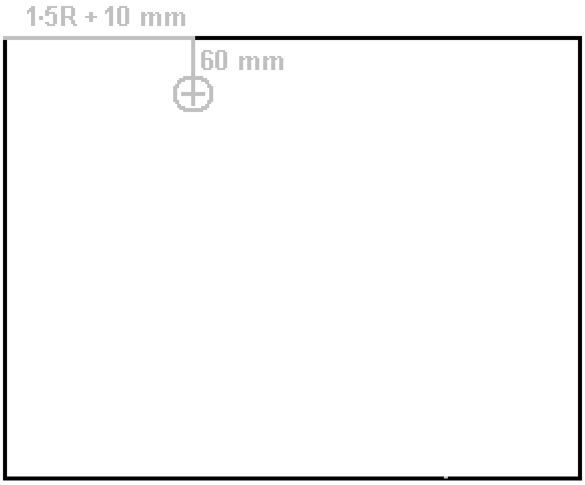
The next thing to do is to make the supports for the flywheel. When the flywheel is spinning it has a lot of energy in it, so we want the flywheel supports to be robust and so I suggest using material which is at least 9 mm thick and preferably thicker than that.

Measure the diameter of your flywheel – probably 200 to 250 mm. Divide by 2 to get the radius "R" and add 30 mm to R as the height which the flywheel will be above the base board. Mark your material one and a half times R in from the edge and a point R + 30 mm above it. That is to be the centre of the axle. Draw a line 80 mm long at a height of 50 mm above the axle, and join the ends to the base like this:

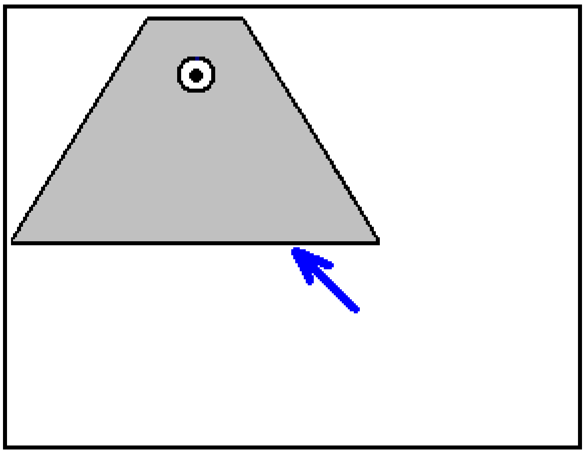


Mark the diameter of your bearing centred on the axle point and then cut out that circle using a coping saw or a jigsaw, being sure to keep the blade perpendicular to the sheet material. If possible, stay slightly inside the circle and then use a wood rasp or coarse sandpaper to produce a perfect circle of exactly the right size so that the bearing is a tight push fit in the hole.

Next, measure a distance of 1.5R + 10 mm (if your flywheel has a diameter of 200 mm then this distance would be 160 mm) in from the edge of a sheet of material and in a distance of 60 mm and mark that point as it is the axle position for the second side support:

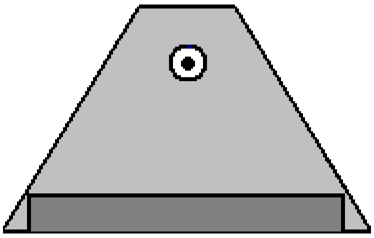


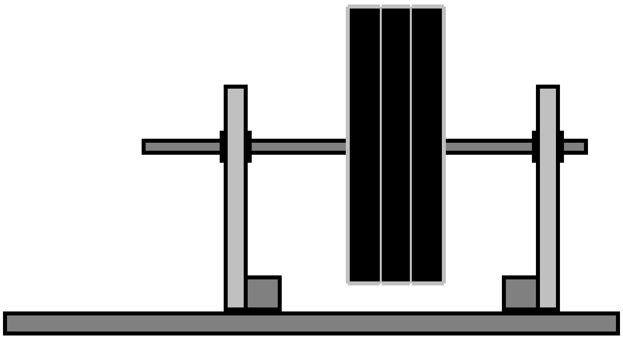
Mark a bearing circle, cut it out and insert the second bearing into that hole. Place a piece of axle material (or a length of dowel of exactly the same diameter) in the bearing and position the first side so that the axle material passes through both bearings, aligning them exactly. Mark around the edges of the first side, being very careful when marking the edge which will become the base of the second side:



Cut out the marked lines and work the bottom edge very carefully to make it exactly the same as the first side as that ensures that the axle will be exactly horizontal.

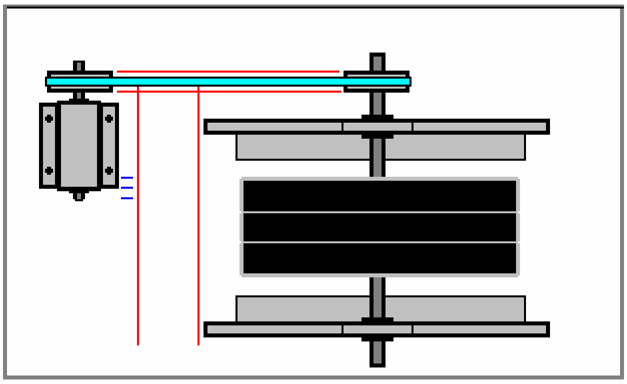
Attach one side to the base board using a piece of timber 50 x 50 mm x the length of the side. Attach a similar piece of wood to the bottom edge of the second side and attach it firmly. Pass the axle through the first side, then thread the second side on to the axle and attach the second side to the base board:





Using a belt and pulley link between the drive motor and the flywheel allows the link to be constructed by the average person, however, great care is needed to get the alignment right. First, the pulley wheels are attached to the flywheel shaft and the motor spindle. Then the drive belt is looped over the pulleys and the motor moved to make the belt fairly tight. Parallel lines drawn on the baseboard makes it easier to get the axis of the motor and the axis of the flywheel exactly parallel. You can then move the motor slowly forward to where it is clearly in the wrong position. Mark that point. Edge the motor slowly back until it is again clearly misaligned. Mark that point. The correct position will be very close to the position half way between those two marks.

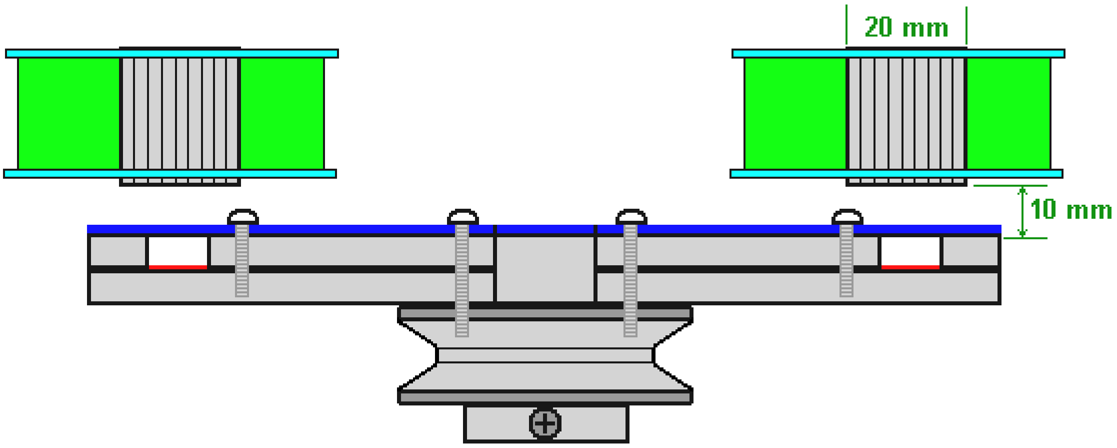
Use a set square (or fold a piece of paper to form an exact right angle) and mark the base board exactly underneath both sides of the flywheel pulley and draw two lines at right angles to the flywheel axis, going through those two points. If the motor is aligned correctly, then the belt should be exactly above and between those two lines:



When the motor is positioned exactly, hold it in position and mark the positions of the retaining bolts or screws. Removing the motor, drill holes if using bolts or very carefully start the retaining screws into the base board. Then replace the motor and bolt or screw it in position with the drive belt running over both pulleys.

John Bedini's design calls for the generator rotor to be directly attached to the flywheel shaft. This is an aluminium disc with magnets attached to it. As the disc rotates very fast, the magnets need to be very firmly attached to the aluminium. In spite of the fact that aluminium has a major damping effect on magnetic fields, magnets do not stick to aluminium and so a strong mechanical bond is needed. John's drawing shows the magnets inset into a thick aluminium plate. That is not impossible, especially if small diameter magnets are used, but the magnetic field will be different if the magnets are surrounded by aluminium on all sides except their South pole faces. For example, if backed by aluminium and encased in epoxy resin will produce a different shape of magnetic field, and although that form of construction is much easier, I suggest doing it the way that John's sketch indicates.

If you have a drill press, you should be able to drill accurately enough to make construction easy. Otherwise, as we want a perfectly balanced rotor for high speed rotation, we can drill the axle hole and then measuring out from the hole, mark the edge of the disc and then cut it out. Neodymium disc magnets of 10 mm diameter and grade N52 would be convenient as a 10 mm diameter drill bit fits into most household drills and the diameter of the corresponding coil cores can be 20 mm to give four times the cross-sectional area of the magnet. The rotor can be constructed like this:



Here, two 5 mm thick discs of aluminium are bolted together and to the flywheel pulley, being careful to ensure that the bolts are in positions which balance the rotor disc. The red strip under the magnets indicates glue with "Impact" Evostick being the preferred glue as it is very powerful and sticks to smooth metal better than epoxy does. The blue strip indicates a thin sheet of rigid plastic covering the rotor face and enclosing the six magnets. Following what Robert Adam said after years of experimentation, I suggest that there is a 10 mm clearance between the face of the magnets and the coil cores which they energise. The coils have 200 turns of 0.8 mm diameter wire and being power gathering coils, it would be normal to have them 50% wider than they are deep as that gives a better sweep of the rotor magnet flux through the coils.

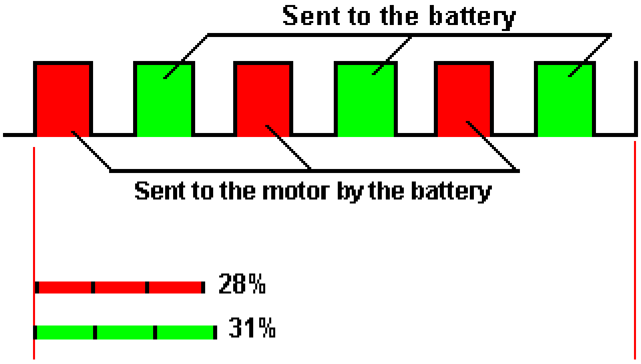
In John's design, all of the six coils are connected "in series", that is, in a chain and if John's documentation shows his system correctly, then there is no rectification or storage capacitor. However, as the generator power is being fed back to a battery which has definite Plus and Minus connections, I personally would use four UF5408 diodes in a bridge, feeding a 35-volt 22000 microfarad capacitor. Please understand that I do not recommend that you build John Bedini's acid pulsing design as this document will go on to describe a highly effective and much safer motor-generator design.

Let me remind you of what John Bedini says in his document: "I must give a very stern warning at this time that if the voltage developed is too high, the battery will explode. Use the utmost care. Test setups in my lab have proved that this can be dangerous. Do not build the device and experiment with it unless you know what you are doing. The ions in the electrolyte are being stressed. The electrolyte in the battery goes wild and the ions race backwards giving off hydrogen and oxygen gas. I must make a stern warning here. The time of the stimulating pulse is very important. If the time is too long the battery will burn itself out. If the pulse time is too short the battery will never recover its charge. We must remember that, if the battery is applied to the energiser longer than normal, we must burn up the excess energy to keep the battery cool. The problem becomes one of an embarrassing excess of energy, not a shortage".

So, let me stress again that although John's system has a flywheel, it is not primarily a device for extracting energy from gravity. While it has an electrical generator it does not feed the energy generated continuously back to the battery to recharge it. Instead, it is a system intended to push resonant pulses into a lead-acid battery to make the battery electrolyte behave in a way which is very far removed from the way that a lead-acid battery is expected to perform. As I have already said, I do not encourage you to do that as I consider it to be both dangerous and unnecessary.

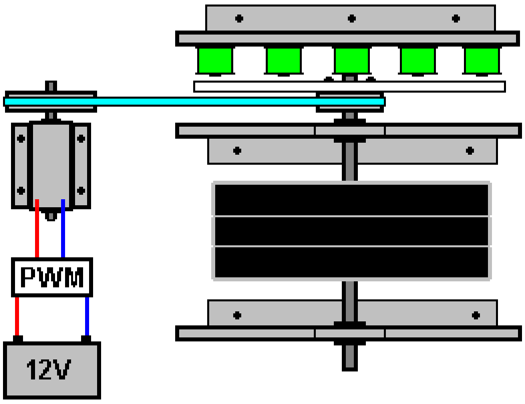
There are alternative ways of using this equipment. The flywheel axle could extend through John's generator rotor and have one or more other rotors mounted on it, energising additional stator coils. The commutator could be scrapped and a battery voltage sensing switch used to recharge the battery conventionally (and safely) from the generator and when fully charged again, switch to charging a second battery. The flywheel could be geared differently, spinning a separate generator with an increase in rotational speed due to the flywheel axle having a larger pulley than the pulley on the generator. However, let me suggest a method to experiment with.

The pulsed wheel system described in chapter 17 has a proven output which is three times greater than the input needed to make it operate. The drive for that wheel is by coil pulsing which is not affected by the Lenz Law effect and so is efficient. If we use an ordinary commercial motor to drive the rotor, then we will have to accept the drag described by Lenz. However, John Bedini is undoubtedly very experienced and you will notice that in his design he drives his motor with pulses:



And in the suggested pulsing diagram the pulses powering the motor are only 28% of the time, which means that the motor is not being powered for three quarters of the time. That fact reduces the current needed to keep the generator running. The recharging pulses applied to the battery are only applied for about one third of the time. Mind you, John is using those battery-charging pulses to achieve resonant charging.

It may be that as each output coil is disconnected when every second magnet passes by them, that may store additional energy in the coil, making the following actual output pulse more powerful. Although John's designs are frequently based on subtle physical arrangements, I suggest that we do not actually attempt to follow his design exactly, so please understand clearly that the following description is not an attempt to replicate John Bedini's design directly, but instead to create a somewhat similar configuration . It would be really nice to eliminate the battery in spite of the fact that John views the battery itself to be a free-energy generator. So, I would suggest that we dispense with the commutator switching and use an ordinary "Pulse-Width Modulator" ("PWM") which is often called a "DC Motor Speed Controller". While we are testing the device, we will use a battery although we aim to operate without it when the system is completed. The initial arrangement is like this:



The 12V battery power supply to the motor passes through the "PWM" controller which switches the current On and Off many times per second. The ratio of the On timer to the Off time is called the Mark/Space ratio and it controls the amount of power fed to the motor.

The John Bedini arrangement has just six magnets and six coils, but for this application I suggest using twelve magnets and twelve coils. The first step is to try to get the system running on part of its own output. In this case we are not trying to feed the highest possible voltage spikes into a battery, but instead are trying to generate a suitable power supply for the motor.

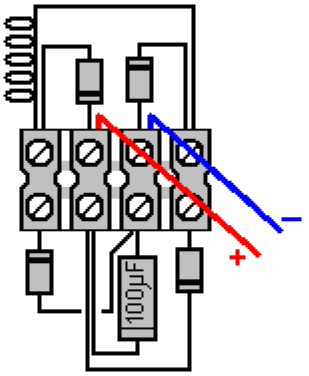
For this, we take the output from one coil, rectify it with four 1N5408 high-speed diodes and feed the output into a capacitor. A voltmeter across the capacitor shows what voltage is being developed. As the output voltage is almost certainly less than the motor needs, the coil is replaced with two coils connected in series and the voltage measured again. If, perhaps, it takes four coils to get to the motor voltage or higher, then the motor input is quickly switched from the battery to the coil power supply from the four coils.

The coil output is probably not sufficient although adjusting the PWM setting might be able to compensate for that. After all, if it can run on its own output, then we really don't care how efficient or inefficient the motor drive is as long as it works. However, assuming that no PWM setting allows the motor to continue running, connect four more coils in series and put them across the first set of four coils. Be sure to connect the two sets of coils with the finish of coil 1 connecting to the start of coil 2, the end of coil 2 connected to the start of coil 3, etc. Connecting the coils in series raises the output voltage fed to the motor and connecting the two chains in parallel raises the output current.

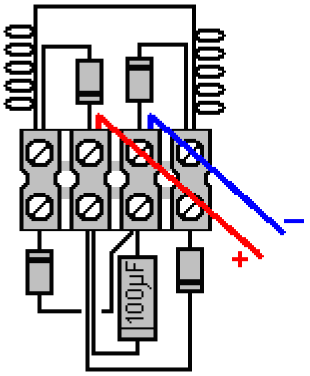
Get the motor speed up again using the battery and then try again with the eight coils. If necessary, the PWM controller can by bypassed and the coils connected direct to the motor. If the motor runs okay with that arrangement, then you have a self-powered generator and the four remaining coils form a free-energy electrical output. If it is found that all twelve coils are needed to keep the motor running, then either or both of the next two options should produce success. You can raise the voltage from every coil by increasing the number of turns on each coil. I would suggest doubling the length of wire in each coil. And/or put an identical rotor and stator arrangement on the other end of the flywheel shaft, giving you an additional twelve coil output.

Please remember that this is only a suggestion and has not been built and tested at this time. If you do build and test it, then please let me know how you get on at engpjk (at) gmail (dot) com.

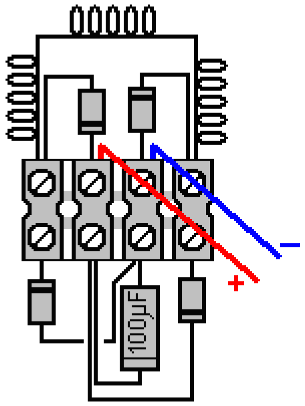
The diode bridge can be constructed without needing to solder as ordinary electrical connector strips can be used:



①



②



③

Here, we have the connections for using one coil, two coils or three coils although any number of coils connected in series can be used.

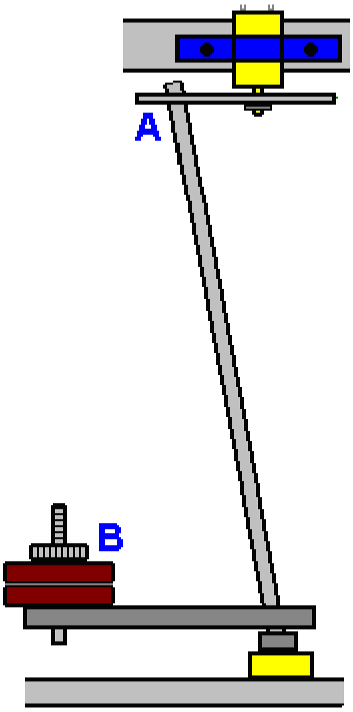
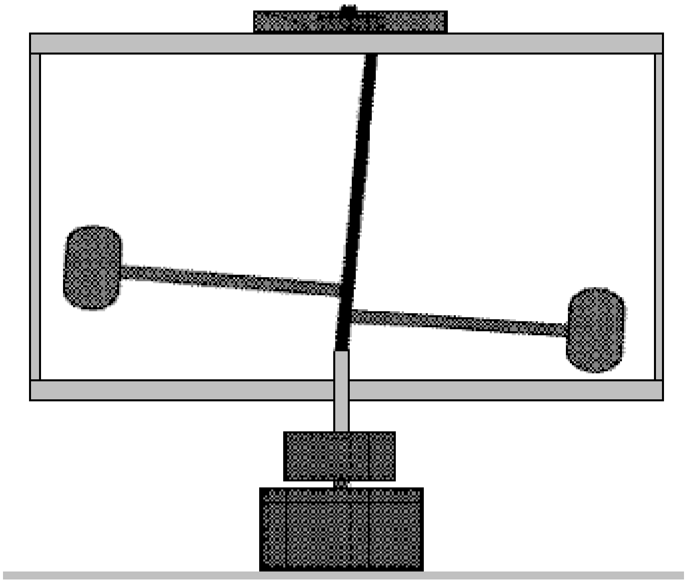
Chapter 20: Building An Impulse Generator

Many people have the mistaken impression that it is not possible to extract useful power from what they call "gravity". They say that a falling weight can indeed do useful work, but then the weight has to be raised again in order to perform more useful work. This is, of course, a very mistaken impression, especially since useful work has been produced by practical devices for many centuries now. Water flows downhill under the influence of "gravity" and that water flow powers water mills which grind grain, operate bellows and power hammers. It also powers massive hydro-electric schemes producing many megawatts of electrical energy, so please don't tell me that "gravity" can't do useful work.

The argument about a falling weight needing to be raised up again before it can do 'useful work' again certainly sounds reasonable, but in 1939 William Skinner of America demonstrated that it is possible to have a weight fall continuously without the weight getting nearer to the ground. Initially, that sounds impossible, but it is not impossible if the weight is always falling sideways. William produced substantial power by moving the top of a weighted shaft around in a circle. That unbalances the weight and it falls sideways to reach a stable position. But the weight never gets there because the top of the shaft is moved continuously to prevent that happening:



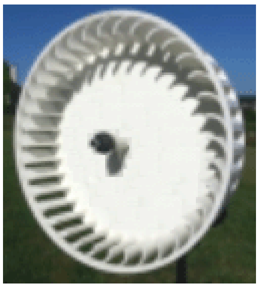
William's video is at: http://www.britishpathe.com/video/gravity-power and the principle has been taken up recently in the patent application US2014/0196567 of David W. John who shows several variations of that basic arrangement, including this one:



This is the same as William Skinner's method as the top of the shaft is moved in a circle and the weights follow the top of the shaft, falling continuously in a circular path at a far greater level of power than is required to move the top of the shaft. This demonstrates very clearly that it is certainly possible to extract useful work from what we call "gravity", (in passing, there is no such thing as 'gravity' which pulls things towards the Earth, the reality is that the effect is actually an imbalance in the universal energy field in which we live, and that imbalance is a push towards the Earth as Newton correctly deduced. The universal energy field is called the zero-point energy field, the aether or any one of many other names).

This, however, is only one of the factors involved in the energy gain produced by this generator as we have inertia and acceleration to consider as well. Let's start with acceleration. There is an excellent lecture by Mike Waters here: http://world-harmony.com/max-velocity-turbine/ although the video quality is not by any means perfect. It does contain a most astonishing statement worthy of the Hall Of Fame of sayings where Mike states that perpetual motion is of no practical use as it just goes round and round. If you give me a disc which goes round perpetually of its own accord, I will promptly attach magnets to it and mount stator coils opposite those magnets and extract free electricity from it for ever.

However, that aside, Mike describes a simple wind turbine design of his which is highly efficient. He points out that as wind flows past an obstruction, it speeds up. He uses this fact to boost the performance of his wind turbine. Next, he puts the turbine blades as far from the axle as possible in order to get the largest lever arm for the wind force on the turbine blades. The design is a simple circular disc forming the obstacle for the wind, and turbine blades mounted around the circumference of the disc:



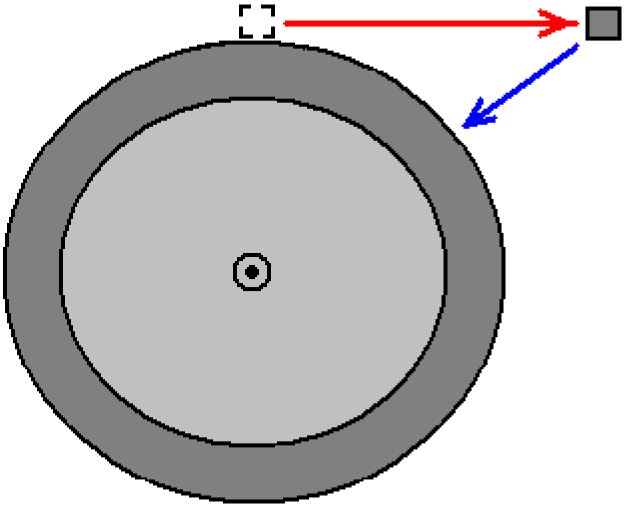
The performance is most impressive with the generator producing power at a wind speed of just 1 kilometre per hour. To understand that, consider the fact that you can walk a kilometre in about ten minutes, so a wind speed of one kilometre per hour is only one sixth of your walking speed.

Mike points out that the force turning the generator is proportional to the **square** of the wind velocity. That means if the wind speed doubles, then the force powering the generator goes up by a factor of four. If the wind speed catches up to your walking speed, then his generator output would increase by a factor of 36 times. So the main point here is that any *acceleration* boosts the generator output. So, just to get the operation clear in your mind, Mike's wind turbine has the wind flowing directly on to the circular plate and to get past it, the wind accelerates sideways to flow around the plate and continue on along its normal flow path. However, the wind accelerates as it moves sideways and so is moving faster than the general wind speed when it reaches the turbine blades at the edge of the disc and so provides a substantial energy boost to the rotor disc. That action, of course, is not limited to wind generators.

Engineers get the impression that a flywheel is just a storage device for kinetic energy and while a flywheel does indeed store energy, even to the extent that some city busses are powered by a flywheel, that is not the only important thing that flywheels do – they also rotate on an axle. Big shock ! Flywheels rotate on a pivot point. I would be very surprised if you didn't already know that. But, are you aware that rotation at a constant speed produces continuous acceleration? Like the William Skinner design, it takes some explaining as to how a constant rotational speed produces acceleration. It's all Newton's fault !!

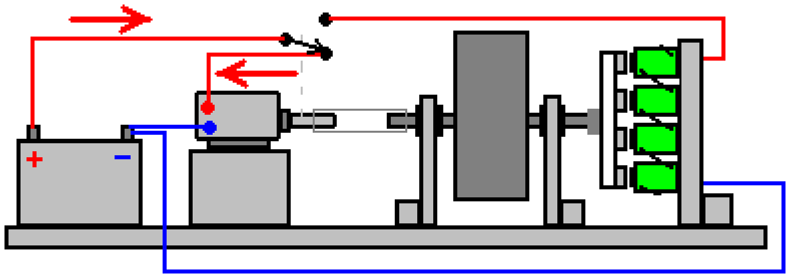
Newton pointed out that if something is started moving, then it will continue moving in a straight line until some force or other acts on it to change its movement. This is a little difficult to understand as we live on a planet whose 'gravity' affects all moving objects very considerably, and the air surrounding the planet also acts on moving objects very considerably. We are so used to these things that we find it difficult to understand that in deep space an object will tend to continue moving in a straight line for a very long time indeed.

Suppose then, that we have a flywheel and we have glued a block of steel to the rim. We spin the flywheel at a speed so high that the glue joint breaks and the steel block flies off on its own. It would be like this:

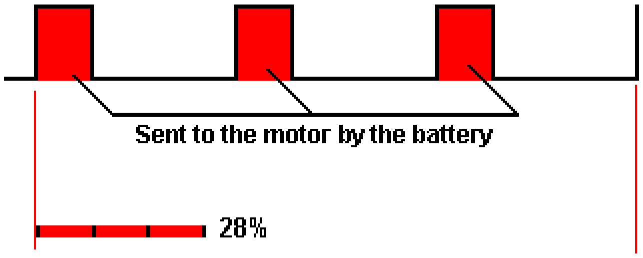


The steel block flies off (horizontally in this case) as shown by the red arrow. That is what the steel block would do if left alone and not bothered by any other forces. But, if the glue joint did not fail, being attached to the flywheel, the steel block would be in the position shown by the blue arrow. University professors who specialise in this subject, describe this as "an acceleration" inwards along the blue line, so although the flywheel is rotating at a constant speed, every molecule of steel in the flywheel is constantly accelerating inwards and acceleration produces an increase in energy. The larger the flywheel, the greater the effect

There is also another factor which is often ignored and that is inertial impact (the impact of two things colliding) and the energy gain from that is substantial. To give you some idea of how powerful this is, if you spin an unbalanced rotor it produces twenty times more thrust than the engine of a jet aircraft. For example, John Bedini has run a small motor/generator in self-powered mode for years on end, using both a small flywheel and the inertial drive of a pulsed DC motor:

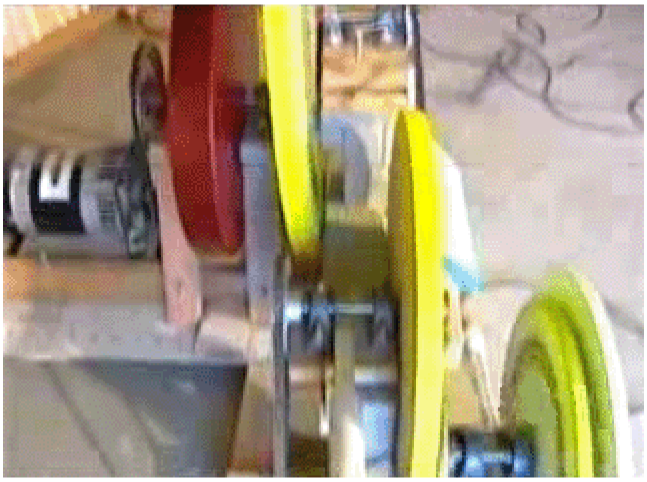


The DC motor is provided power in three short pulses per turn of the motor shaft, the switching being performed by contacts on the motor shaft. The timing of the pulses is like this:



We need to be careful not to underestimate the effect of inertial impulses, and John's pulsing of his DC motor causes it to keep the flywheel spinning for three times longer than the duration of the pulses. There is a distinct inertial gain in energy when the motor is suddenly powered and applies a short thrust to the flywheel axle. In passing, it might be noticed that while those motor pulses are only there for a quarter of the time, the motor is receiving some 3000 pulses per second, so the energy gain from the pulsing seems almost continuous.

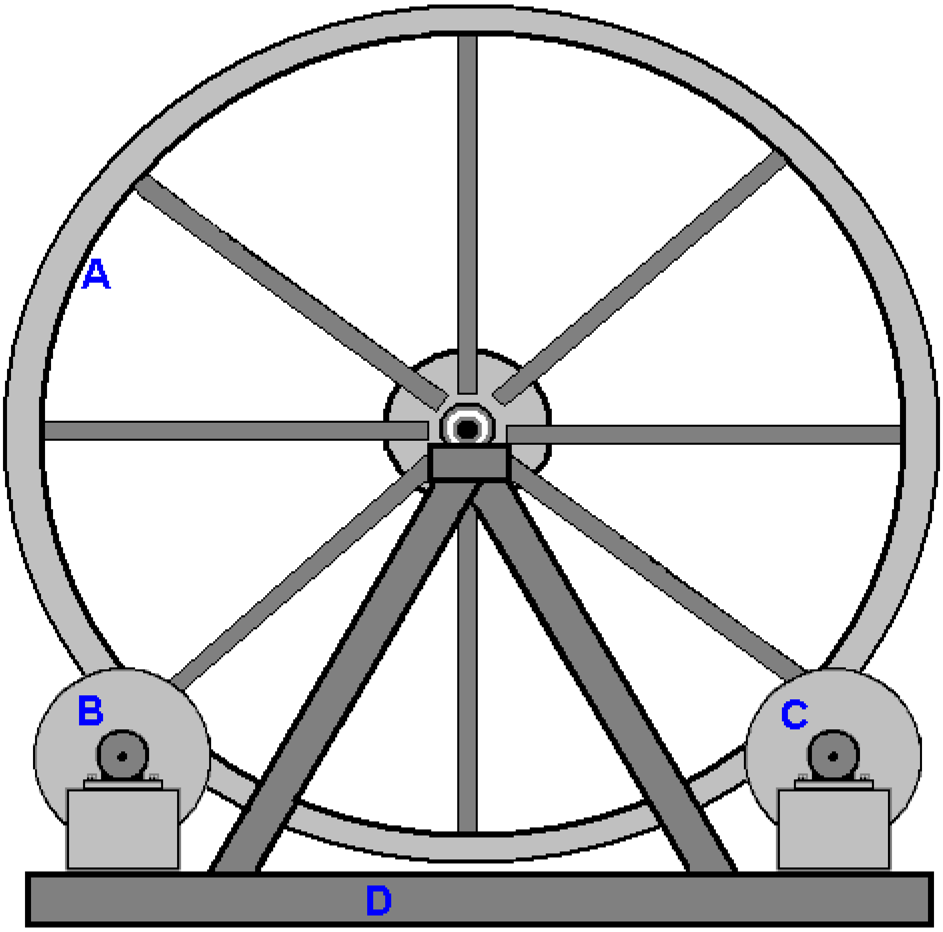
So, overall, we can get an energy gain from 'gravity' and from acceleration and from inertia. Chas Campbell of Australia who is experienced in building successful gravity-powered generators has very kindly agreed to explain to us, step by step, how to construct a self-powered generator of his latest design. Initially, Chas built a very successful motor/generator design which is described in chapter 4 and which looks like this:



Driven by an AC mains motor, once running, this generator can be powered from its own output and when powered like that it can also supply power for other pieces of equipment. That generator gains power from the acceleration effect of the flywheel and from the inertial impacts of the mains motor pushing one hundred times per second. In my opinion, it would probably work more effectively if powered through a mains dimmer light switch. Those switches are available in powers of up to one kilowatt and they can be turned down slightly to give a more noticeable On/Off effect for those one hundred pulses per second.

However, Chas has very kindly agreed to share his latest flywheel design so that anyone who wants can make and use one for himself. As people's circumstances and skill levels vary so much around the world, we will explain three different ways to build his design – two ways when building in steel and one when building using wood.

Chas' latest design uses either two or three flywheels – one large one to drive the output generator and either one or two small flywheels to keep the large flywheel rotating. An additional inertial effect is produced as the small flywheels use a drive mechanism which is not continuous. The arrangement looks like this in broad outline:



Here, the large flywheel “A” is supported on a triangular frame “D” and smaller flywheels “C” and possibly “B” give the large flywheel a brief push on its way twice per revolution. The target speed of rotation for the large flywheel is just one revolution per second, so this is not an intimidating generator design and it is well within the constructional ability of most people.

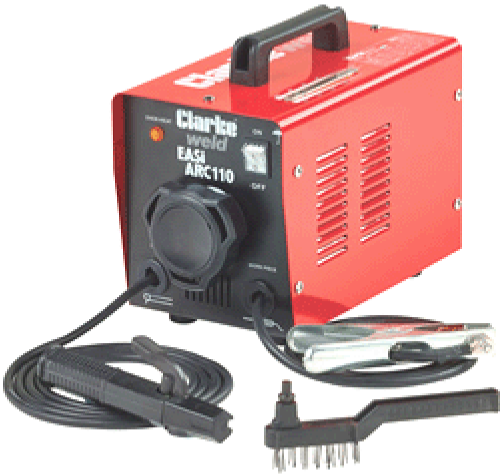
To be really effective, a gravity-powered generator has to be heavy (and usually, large in size as a result of the weight) and so, although alternative methods can be used, it is normally built in welded mild steel. If you have never built anything in steel, let me assure you that it is not a difficult thing to do, and yes, I have built in steel, starting as a total beginner. However, while mild steel is easy to work and weld, stainless steel is much, much more difficult, so avoid stainless steel. Steel pieces are cut and shaped using an angle grinder like this:

And while the picture shows a handle sticking out of the side of the grinder so that you can use two hands, it is generally more convenient to remove the handle and just hold the grinder in just one hand as it is not heavy. When working steel, wear a pair of “rigger” gloves which are strong, reinforced gloves which will protect your hands from sharp steel edges and always wear eye protection.

If you are going to be drilling steel, then a mains powered drill is needed as battery-powered drills are just not up to the job unless it is just a single hole. When drilling steel it is helpful to have an additional hand grip.

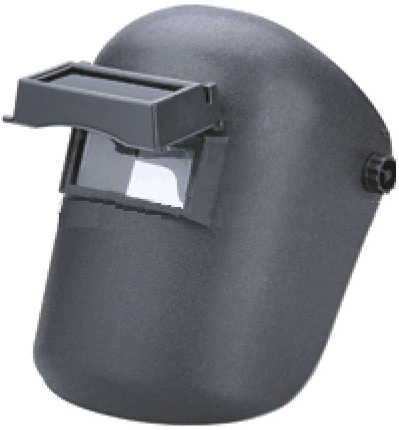
With the drill shown above, the hand grip clamps on to the ring just behind the chuck and can be set at any angle. Steel pieces are joined together by welding. Some welders are quite cheap. Most types can be hired for a day or half a day. It is also possible to shape the pieces and have a local steel fabrication workshop weld them together for you and making a good welded joint takes only a second or two. The really vital thing is never look at a weld being made unless you are wearing a welding visor or welding goggles, as you can damage your eyesight looking at a welding arc without protection.

If you decide to buy a welder, then be sure to get one which will run on your house mains supply, otherwise you have to upgrade your house wiring to carry the higher current. This welder would be suitable, and at the start of 2016 it costs only £60 including tax which is about 82 euros or US $90.



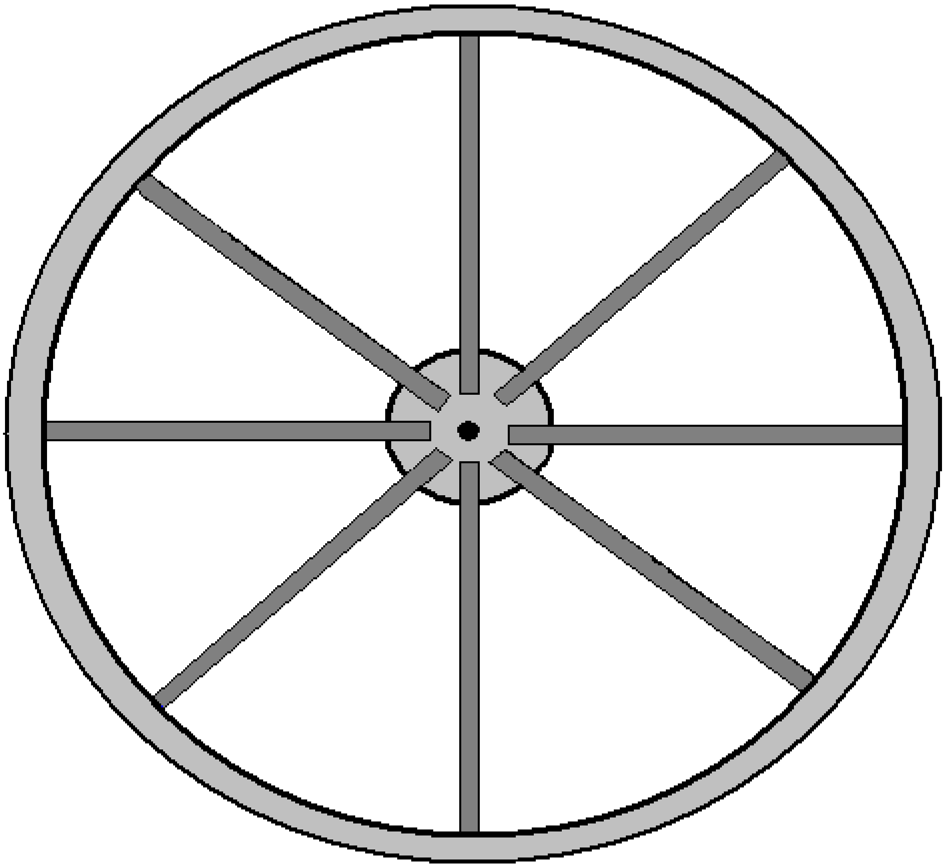
With this “stick welder” the silver clamp on the right is attached to the metal to be welded and a 2.3 mm diameter coated welding rod placed in the black clamp on the left. The stick is then applied to the welding area and the coating on the welding rod becomes a gas cloud, shielding the hot metal from the oxygen in the air. When the weld has cooled down, there will be a layer of oxide on the outside of the joint and so the back of the wire brush is used as a hammer to break up the layer and the wire brush used to scrub the joint clean.

However, the most important item of equipment for anyone doing welding work is a protective helmet. There are many different designs and widely varying costs. Many professional welders choose one of the cheapest types which look like this:

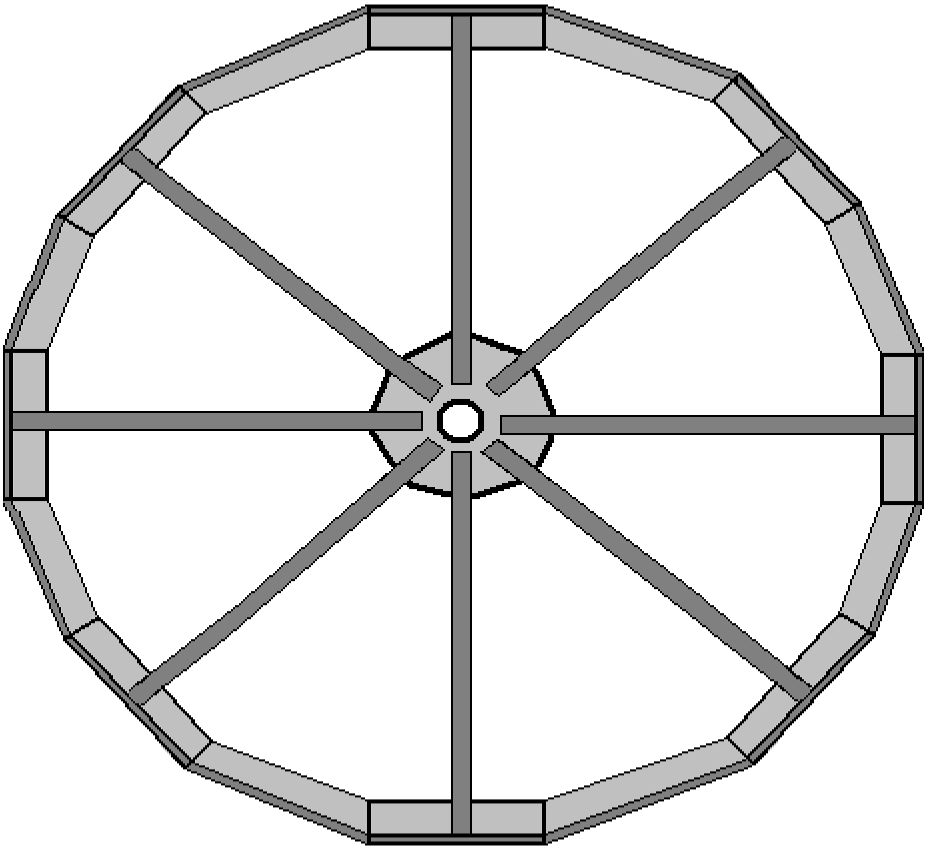


This type has a clear glass screen and a hinged safety filter to allow safe welding. Professionals adjust the hinge tension so that the filter can only just stay in its raised position. The welder then positions the joint pieces in their exactly correct position while looking through the plain glass, and when ready to start the weld he just nods his head which makes the filter drop into place and the weld is started. Never, ever, try welding without proper eye protection

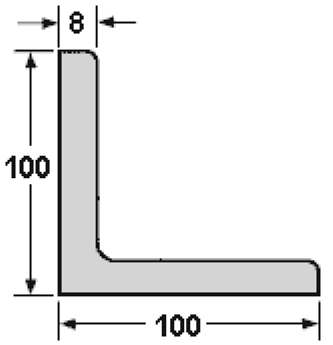
The large flywheel which Chas prefers, looks something like this:



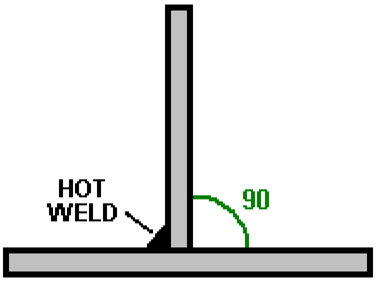
The wheel has a diameter of two metres (six and a half feet) and is a central hub with an axle, eight spokes of 50 x 50 mm steel box section welded to the 200 mm diameter hub and to the rim of the wheel. What is unusual about this design is that the axle bar is stationary and the flywheel rotates around it. However, bearing in mind that some people building this generator will be located where there are no local steel fabrication businesses, Chas has produced a much more simple design which will work well using straight edges like this:

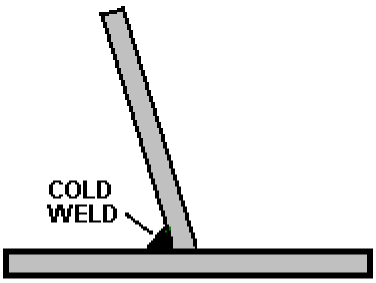


For this construction, each of the eight spokes has a square-cut length of 100 x 100 x 8 mm angle iron welded to it. The angle iron which weighs about 12.276 Kg per metre is shaped like this:

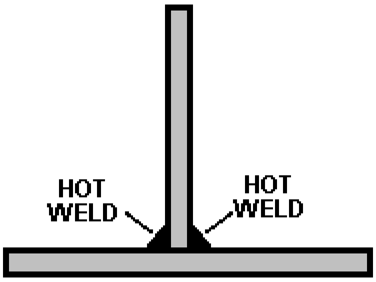


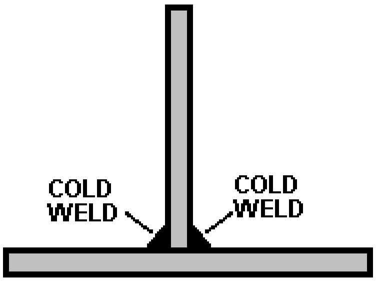
Welding is easy to learn and it is a brilliant method of construction … but it has one major problem. When a joint is made the two pieces of steel melt and merge together. This can happen in a tenth of a second. Don't put your finger on the joint to see if it is still hot, if it is, then you will get a painful burn and that should remind you not to do that again. That heat is the problem, because when steel gets hot it expands, and when it cools down it contracts. That means that if you were to set up a piece of steel at exactly a right angles and weld the pieces together then as the joint cools down it contracts and pulls the joint out of alignment:





Please don't imagine that you can just push the vertical piece back into position as that isn't going to happen because the joint is instantly very, very strong. Instead, you use two quick welds of equal size, with the second one being 180 degrees opposite the first one:



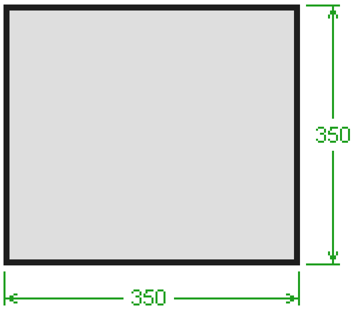


Then, as the welds cool down, they pull in opposing directions and while it produces stresses in the metal, the vertical piece stays vertical. Let the welds cool down in their own good time, taking perhaps ten minutes to cool properly. Do **not** apply water to the welds to speed up the cooling as that actually alters the structure of the steel and you really don't want to do that.

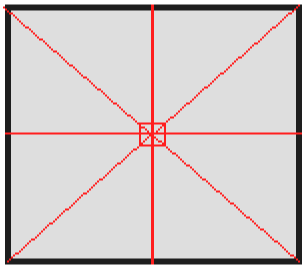
Metal can be cut quite readily using a cutting blade in your angle grinder but be sure to install the blade so that it rotates in the direction shown on the blade. The blade is likely to look something like this:

When cutting or grinding **always** wear protective goggles to make sure that you don't get a metal fragment in your eye – eyes are not readily replaceable !! If you do get a small steel fragment in your eye, remember that steel is highly magnetic and so a magnet may help in getting the fragment out with the minimum of damage, however, it is much, much easier to wear goggles and not have the problem in the first place.

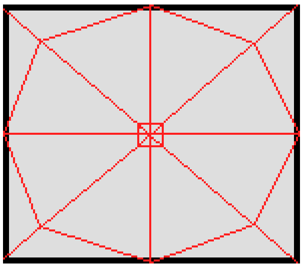
For this generator, we start by making the hub. While a circular shape can be produced using simple tools, there is actually no need and so we can just use straight edges which are much easier to produce. So, for this, we cut a square of metal 350 mm along each face:



This is an important structural component and so it would be good if the metal was 10 mm thick or even thicker. We need to construct an arrangement where the 2-metre diameter flywheel is supported on two 16010 bearings which have an inner diameter of 50 mm, an outer diameter of 80 mm and a thickness of 10 mm. For this, a length of mild steel pipe needs to be inserted through the hub plate and welded in position at exactly right angles to the hub plate. But, for the moment, back to our square piece of steel which we intend to become the hub plate of our main flywheel. Draw diagonals from the corners to establish where the centre of the square is, then mark a 90 mm square centred exactly on that centre point, and draw a vertical and horizontal line, like this:



Measure 175 mm out along the diagonals and mark each of those four points. Then, connect those points to make an even octagon:

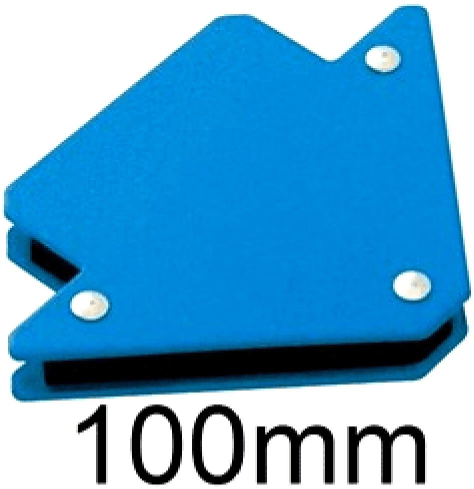


We need to pass a mild steel pipe through the plate in the centre of the square, and we are not going to put in any additional work on the hub plate until we have the pipe in place and its welding is confirmed to be accurate. The pipe is needed to give the thin hub plate stability when rotating around the 50 mm diameter axle shaft, and so, it should be at least 100 mm (4-inches) long when installed. There is a mild steel pipe with 80.78 mm inner diameter and an outer diameter of 88.9 mm and a wall thickness of 4.06 mm. That gives a clearance of just 0.39 mm all around the bearing and allows the bearing to be tack welded directly to the pipe which has a robust wall thickness.

Cut a 300 mm length of the pipe and position it carefully in the centre of the square marked in the middle of the hub plate. Draw carefully around it to show the size and position where the pipe needs to go. We now have the difficulty of getting the pipe through the hub plate. With a powerful plasma cutter that would be no problem and the circular cut could be made quite easily, but it is definitely too expensive to buy one for just that one cut, although hiring one and an air compressor for a morning might be an option.

With the most simple tools you could cut out the largest possible square in the centre of the circle and then use a round file (and a lot of effort) to cut back the remaining metal to make the required circle. A more crude method is to just cut out a square and settle for welding the pipe at the four points where it touches the hub plate. Remember that the moment the weld is made on one side of the hub plate, the other side of the hub plate needs to be welded immediately and both allowed to cool as slowly as possible to avoid heat shrinkage pulling the pipe out of its alignment with the hub plate. Remember that the hub plate will be hot enough to burn you even if the weld only took a split second to make, so take care. In other words, if the pipe is vertical, then (almost) simultaneous welds need to be made on the top of the hub plate and on the underside of the hub plate. The thicker the steel, the easier it is to weld without problems and the pipe is straightforward to weld with its 4 mm thickness. It takes a great deal of skill to weld steel sheet of 1 mm thickness without tearing a hole in the sheet, but thankfully, that is not something which you need to do with this design.

Before welding, we need to stand the pipe piece exactly vertical to the hub plate, with 50 mm projecting beyond the hub plate. This can be done easily with four permanent magnet units intended specifically for this job. They are very powerful and look like this:



These attach strongly to both the pipe and the hub plate and with one every 90 degrees around the axle, it is held very securely in place, leaving plenty of space for the initial welds. In early 2016, a set of four of these right-angle magnets costs £10 in the UK.

Having tack-welded the pipe carefully and quickly on both sides, using welds only 6 mm or so long, and having waited for those welds to cool down fully, make two additional tack welds at 180 degrees to the first two, and then two more pairs so as to have a weld every 90 degrees around the pipe. This leaves you with 50 mm of pipe sticking out of one side of the hub plate and 240 mm sticking out of the other side. We will cut off the excess to leave 50 mm sticking out of both sides. It is surprisingly difficult to cut a circular bar or pipe off at right angles. I suggest that you remove the magnets and mark the 50 mm position and the wrap a sheet of rectangular paper such as an A4 size sheet of printer paper, tightly around the pipe. Make absolutely sure that the paper is tight and aligns exactly when wrapped around the pipe for the full length of the long side of the paper. Mark carefully around the end of the paper and that gives you a clean circular line around the pipe at exactly right angles to the pipe.. Remove the paper and do NOT attempt to cut through the pipe from one side. Instead, make a series of short cuts exactly on the line. Make one cut of perhaps 20 mm, then stop, move on 20 mm and make another 20 mm cut. When you get back to your starting point, continue the process to join up your cuts and remove the excess section of the pipe. If necessary, smooth the end of the cut pipe very slightly with your angle grinder. Do not over do that smoothing and remember to use goggles for both cutting and smoothing.

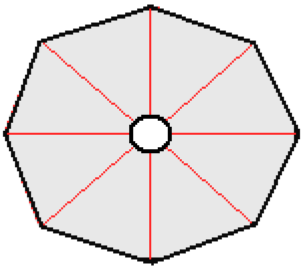
Check your work to make sure that it is square and accurate, as the spokes will amplify any inaccuracies. When the welds have cooled, remove the magnets, turn the construction upside down, supporting it however you wish – a cheap workmate like this:

BLACK&DECKER
Workmate
BLACK&DECKER

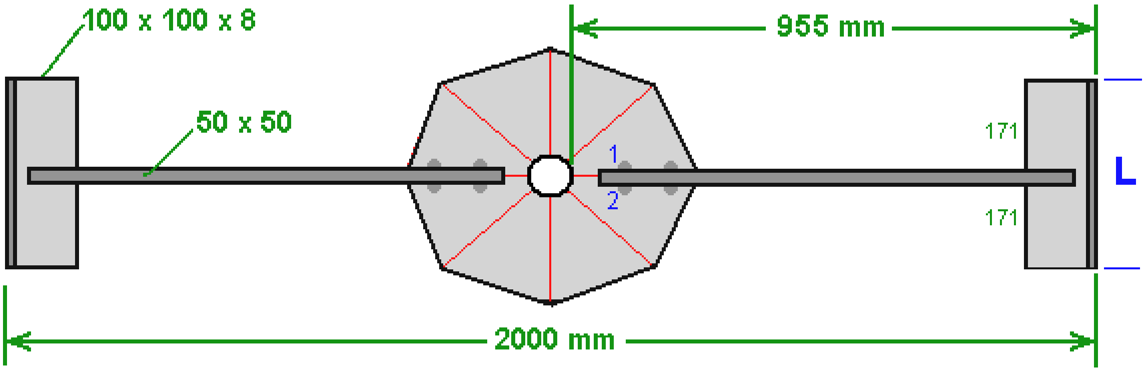
makes a good support for this work and it allows the pipe to be gripped securely while the hub plate is resting horizontally on the bench. The second half of the axle shaft is then positioned very carefully and accurately over the centre of the hub plate, secured with the magnets and tack welded in place.

Even though the flywheel will only be rotating once per second, we now reach the most critical part of its construction, namely, checking that the work so far is accurate enough. For this we use two temporary pieces of notched timber clamped in the bench to support the shaft horizontally so that it can be spun. Spin the shaft and watch the hub plate very carefully. The plate should spin with no sideways movement at all. This is essential because the wheel spokes will amplify any error many times. If the result is good, then award yourself a pat on the back. If there is some sideways movement, then scrap the work and start again with another hub plate and piece of pipe.

If the work is accurate, then grip the pipe in the workmate and cut off the projecting pieces of the hub plate to form a clean octagon:



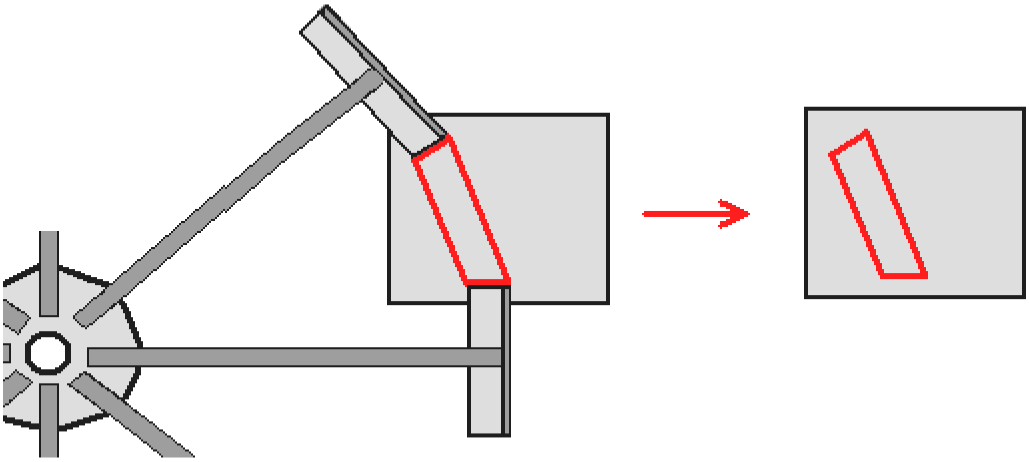
With two spokes welded to the central hub the basic construction will look like this:



The spokes are made with 50 mm x 50 mm steel box section which has good rigidity in all directions. As the overall diameter is 2000 mm that means that the length around the rim will be 2000 x 3.1416 = 6283 mm (if construction is very accurate) and the rim angle iron will have a weight of about 77.13 kilos (170 pounds) which means that in the later stages of building this flywheel most people will need a second person to help lift and manoeuvre it into position. The flywheel weight can easily be increased at any later date by welding additional steel pieces to the inside of the rim – just remember to keep the wheel perfectly symmetrical and balanced around the axle by always matching any additional piece with an identical piece exactly opposite it (that is, 180 degrees away around the rim).

When attaching the 50 x 50 mm box sections to the hub plate be sure to align them exactly and clamp them in place very firmly with steel clamps and double check the position before welding them. This is done by drawing accurate parallel lines on each side of the existing lines, 25 mm out, so that when the 50 x 50 steel is clamped in place, those lines show that the positioning is correct. Also, be very sure that you make two opposing welds to avoid the pieces being pulled out of position. So, in the diagram above, when weld “1” is made, then weld “2” is made immediately so that they can cool down together and heat distortion avoided.

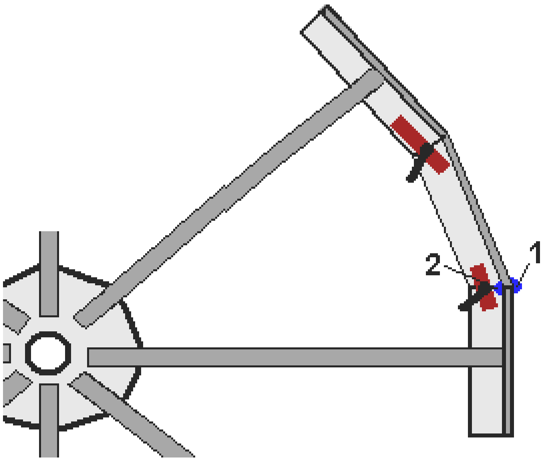
We now need to work out the length of the strip of angle iron marked as “L” in the diagram above. The overall circumference is 6283 mm and it will be divide up into 16 equal lengths, so each length will (hopefully) be 392 mm long. We start by attaching square cut 392 mm lengths to the ends of the box-section spokes and then cut a template in some stiff material such as 3 mm Medium Density Fibreboard. This is done by sliding the flat template material under two successive rim pieces and marking the shape, showing the angles and lengths involved:



Cut out the template shown in red in the diagram above and check it for accuracy between the two steel pieces to make sure that it is correct before using it to mark the piece of angle iron which will be welded in place to close the gap in the wheel rim. The angle iron has the slanted faces cut and then verticals are marked on the vertical face and those are cut separately. Check the piece in place and if the fit is not perfect, use the angle grinder to make the fit as good as possible.

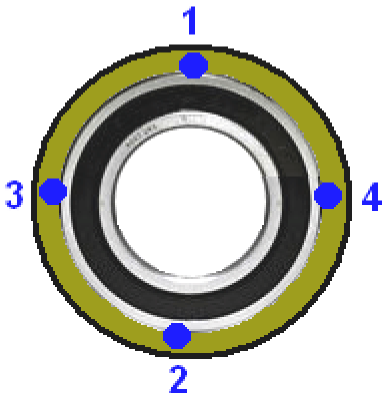
Use two packing pieces above and below, to clamp the angle iron in place aligning it in the horizontal plane, and use robust clamps when doing this:

And when the pieces are positioned perfectly make two of the short welds (“1” and “2”) on the vertical faces, and let the welds cool down before making the next of the four pairs of vertical welds:

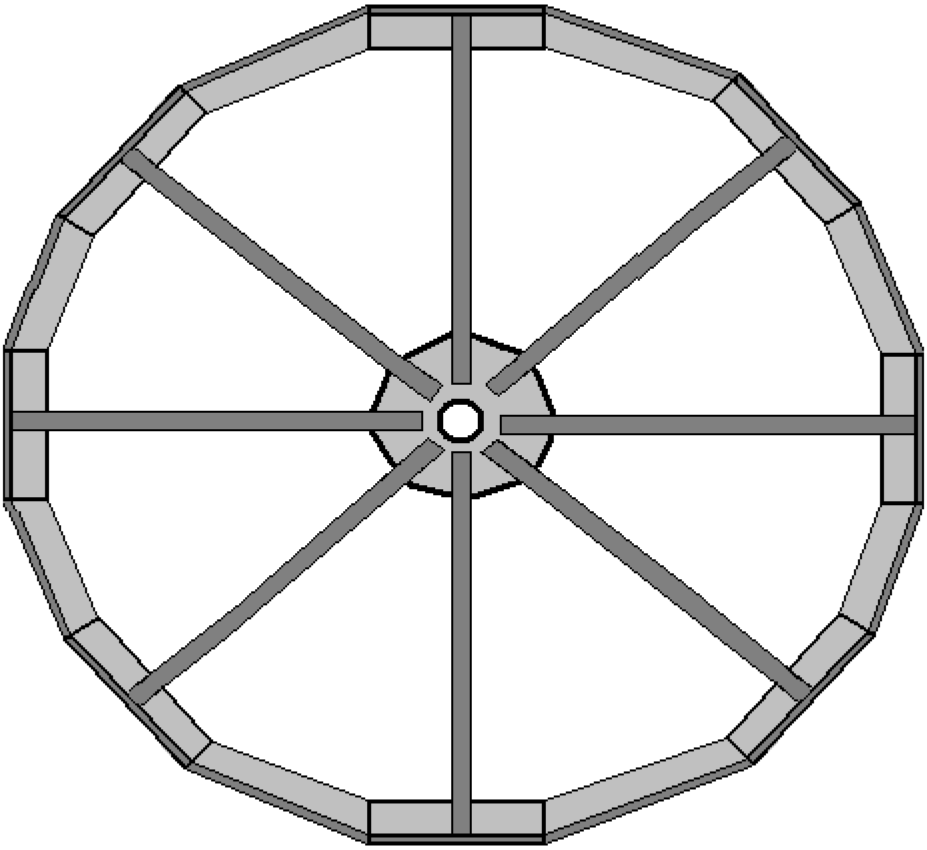


When the welds have cooled down, remove the clamps and packing pieces and make the horizontal welds. You need to make the underside weld and upper weld quickly one after the other. This means that you need access to both faces so that the welding can be completed one immediately after the other. For your first joining piece, the wheel will weight around 50 kilos and that is not a trivial weight to be handling and obviously, as you continue fitting the remaining pieces, it gets progressively heavier. You don’t prop it up high so that you can be underneath it for one of the welds – welding above your head is definitely to be avoided as your head does not enjoy having drops of molten steel landing on it, which is exactly where gravity will direct the molten drops. If you do prop it up at waist height, then stay well to one side when making the underside weld. One possibility is to stand the partially completed wheel upright, so that the underside face becomes a vertical face. The wheel is already a fairly robust construction, but it would be no harm to support it on a rod through the hole in the centre of the hub plate if you are choosing to do all of the welds on a vertical face.

The flywheel is completed by inserting the bearings into the ends of the pipe, making sure that they are exactly flush with the end of the pipe and applying two pairs of spot welds to each bearing. The bearings end up with four spot welds spaced at 90-degree positions:



There are a few additions to be made, but this is the basic wheel which forms the heart of the generator. The overall easy-build flywheel (roughly sketched) looks like this:

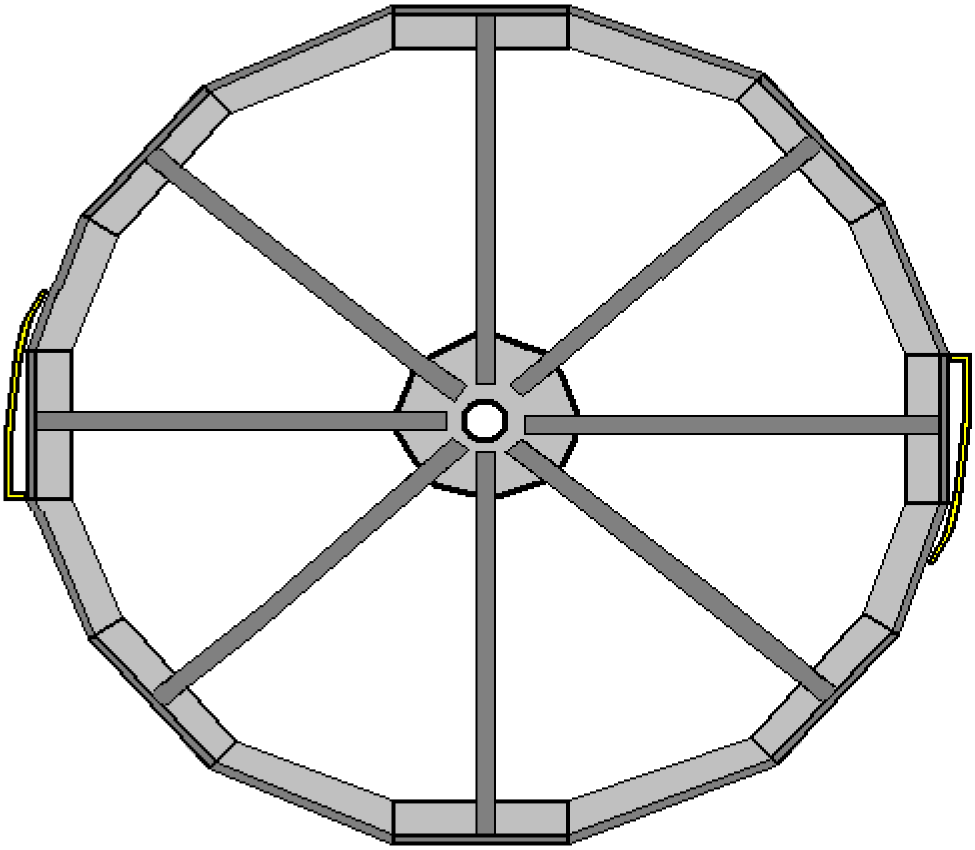


Please remember that when completed, this 2-metre diameter flywheel weighs more than 80 kilos and so to raise it into a vertical position means that you have to lift 40 kilos. While that is by no means impossible, it would be much more convenient to have two people lifting and manoeuvring the flywheel into position, if that is possible

The additions to this large flywheel are two pressure strips which are used to drive the main flywheel. The power for the complete system is supplied to one, or preferably two small flywheels and those flywheels which are easy to spin, pass a thrust to the main flywheel each time that they encounter a pressure strip. As a general rule, (provided that you are not building a space drive) you always keep a flywheel balanced, and so, if you attach something on the right hand side you should attach an equivalent weight on the other side to keep the flywheel balanced. We have the option to add one drive strip and a counterbalancing weight opposite it, or to have two drive strips positioned 180 degrees apart.

With one drive strip and one small flywheel, the main flywheel gets one drive pulse once per revolution. With one drive strip and two small flywheels the main flywheel gets two drive pulses per revolution. With two drive strips and one small flywheel, the main flywheel gets two drive pulses per revolution. With two drive strips and two small flywheels the main flywheel gets four drive pulses per revolution.

The main flywheel drive is caused by making each small flywheel press a rubber-covered cylinder against a rubber-covered steel strip attached to the large flywheel. The additional strips are arranged like this:



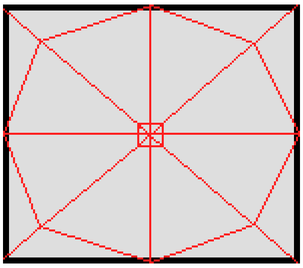
The final detail is something which will prevent the flywheel sliding along the stationary 50 mm diameter axle shaft, which it will do if the axle is not exactly horizontal. If the axle shaft is even 1 degree off the horizontal, the flywheel will keep edging towards the lower end. It is possible to stop the movement with a collar on both sides of the flywheel, Those collars are nice and cheap in the common small sizes but at a 50 mm inner diameter they are very expensive, and the continuously rotating flywheel will be pressing against the stationary collar, causing friction and wear. A suitable way of dealing with this is to use a 51110 size end-thrust bearing like this:

This allows the flywheel to rotate freely even if the axle shaft is not quite horizontal. It is just necessary to lock the outer sides of the two end-thrust bearings to the stationary axle and that can be done cheaply and effectively using a hosepipe clip also known as a Terry Clip or a Jubilee Clip:

Just position the tightening bolts 180 degrees apart even though the whole clip is light.

All right, that is the first way to build the main flywheel and it is the method preferred by Chas, because he lives in an area where there are steel fabrication workshops with experienced welders and professional tools and equipment. However, many people live where there are few facilities and where the Customs charge exorbitant fees which can triple the cost of anything delivered through the postal service. So, here are two other ways of building the flywheel which may be more suited to areas where the conditions are more difficult.

The first method is very much the same, building in welded steel, but this time we will assume that the nicely sized steel pipe is not available. There are various ways around this problem, but probably the easiest is to attach the 50 mm diameter axle shaft directly to the hub plate and let the axle rotate along with the flywheel. For this, we set out and mark up the hub plate as before:



But this time around, the central square is 50 mm in size, and both sides of the plate are marked to produce that exactly centred square. The axle shaft is cut into two equal lengths, but we use the factory machine-cut end and position it in our central square, using four of the magnets to hold it exactly perpendicular to the hub plate. We make two quick welds on opposite sides of the axle, attaching it to the hub plate, positioning the welds half way between the magnets. When the welds have cooled, we make two more quick welds so that the axle is attached at 90-degree positions all around the shaft.

When the welding has cooled down completely, remove the magnets and turn the piece over, clamping the attached axle section in the workbench to hold the hub plate steady. Position the factory-cut end of the second axle piece exactly in the centrally marked box and use the magnets to hold it exactly vertical. Again, two pairs of quick welds are made to attach the axle to the hub plate.

When everything has cooled fully we need to check to see if the result is usable. For this, support the two axle pieces in a piece of timber with a V-notch cut in it. That is, the axle is positioned horizontally, supported near each end in a notched piece of timber. Spin the axle and watch the hub plate very carefully as it spins around. If the hub plate stays steady and doesn't wobble, then your work is excellent and ready to progress further. If the plate wobbles, then scrap it and start again as you will never make a satisfactory flywheel with that plate forming the hub. Every alignment error will be magnified many times at the rim of the flywheel due to the length of the spokes.

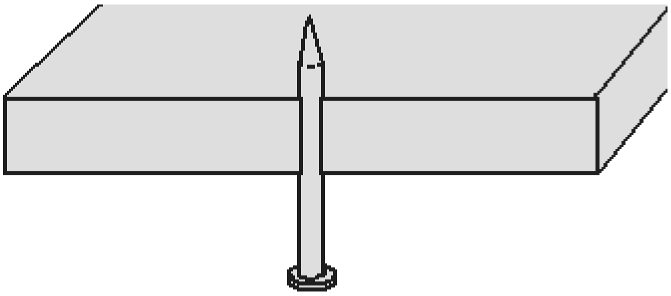
The rest of the flywheel construction is the same except that the 50 x 50 mm spokes are not welded to the hub plate, but instead are bolted there using two 10 mm diameter bolts per spoke. That allows the hub plate and axle to be removed from the flywheel to make things easier if you need to transport the flywheel to a new location at a later date. It is perfectly possible to transport the whole generator fully assembled, using the sort of lorry which transports building blocks for new houses.

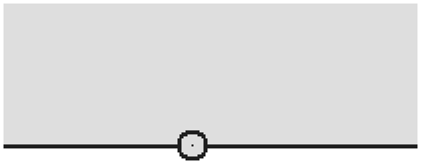
The only other difference for this style of build is that the two bearings are positioned on the support frame rather than being part of the flywheel itself.

The third way of building the flywheel is for places where steel is not readily available. You might think that building in timber is not nearly as good, but surprisingly, it is a very successful way of constructing a heavy flywheel. For this construction we use standard sheets of chipboard, blockboard, or Medium Density Fibreboard. In metric areas of the world, these sheets are 2440 x 1220 mm in size. In American areas the sheets are 8 x 4 feet in size.

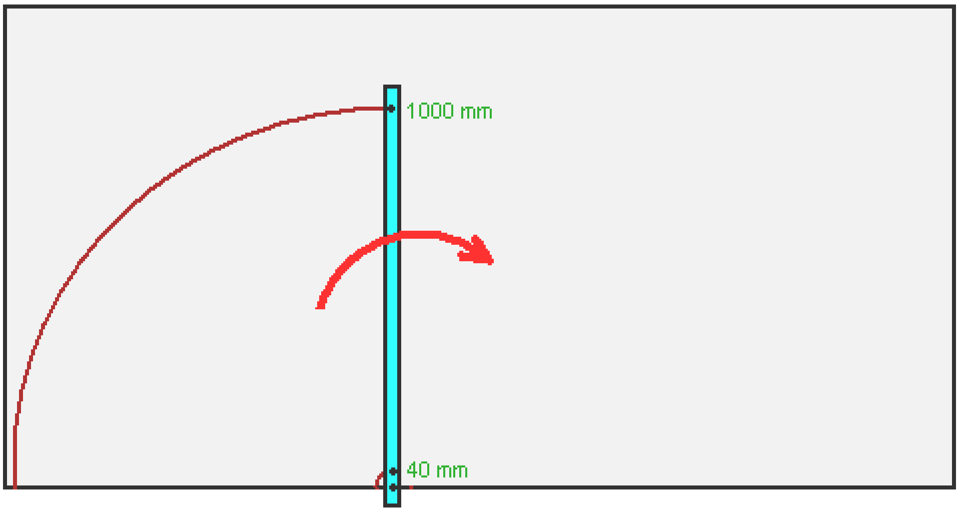
We need to cut several semicircles from these sheets, and I would suggest using 20 mm thick (or failing that, 18 mm thick) sheets. These semicircles will be attached together to form a solid circular flywheel of any thickness we wish. Different varieties of wood and laminate sheets vary very considerably in weight, but a two meter diameter wood disk of 80 mm thickness is likely to have a weight of 90 kilos (200 pounds) and there is no reason (other than cost) why the thickness should not be twice or three times that 80 mm thickness. It also has the advantage that additional layers can be added at any later date if you want the flywheel to be heavier.

I suggest that a timber lath is used for marking the sheets. It is necessary to have the lath pivoted at the exact edge of the sheet and so a nail can be used as the pivot for the marking lath but remember that the nail needs to be inset into the side of the sheet for half the nail depth:

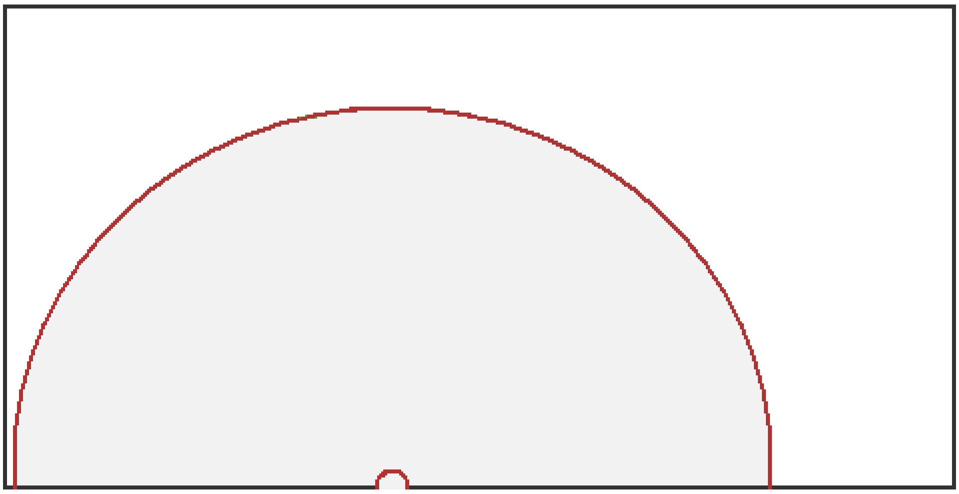




The lath then fits exactly on to the nail which forms a fixed and steady pivot point. The lath has holes positioned at 40 mm and 1000 mm in from the centre of the nail. These holes are only just large enough to pass the tip of a pencil through them:



This marks the board out for it to become half of a 2-metre diameter disc with an 80 mm central hole ready to take the two 80 mm diameter 16010 bearings.



Two of these semi-circular boards are assembled with the join vertical and the next two are positioned on top of those with the joint vertical to give the maximum supporting effect between the components.

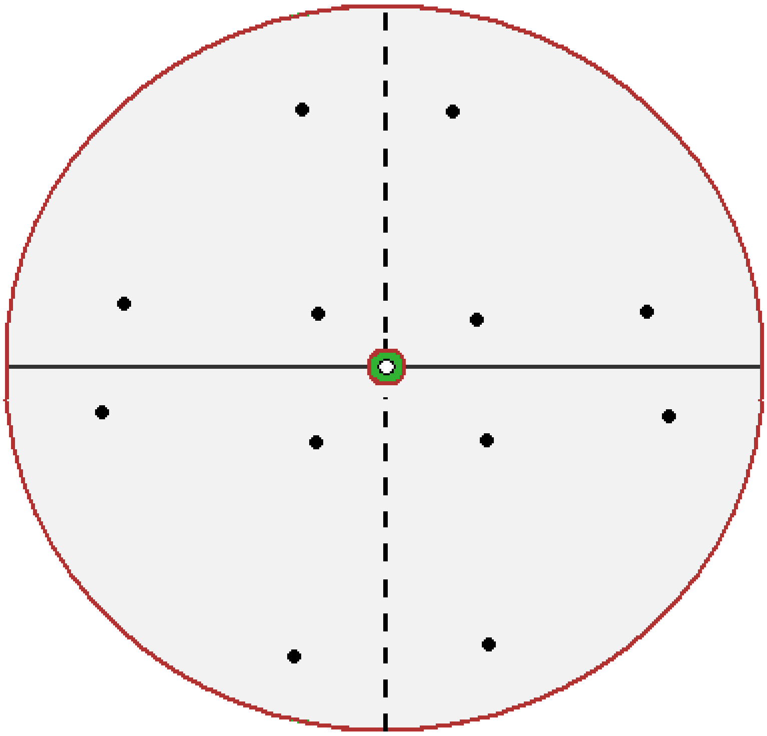
To cut out a component that large, the easiest tool to use is a power jig saw, or if necessary, a drywall saw:

Low Vibration
BOSCH
PST 700 PE

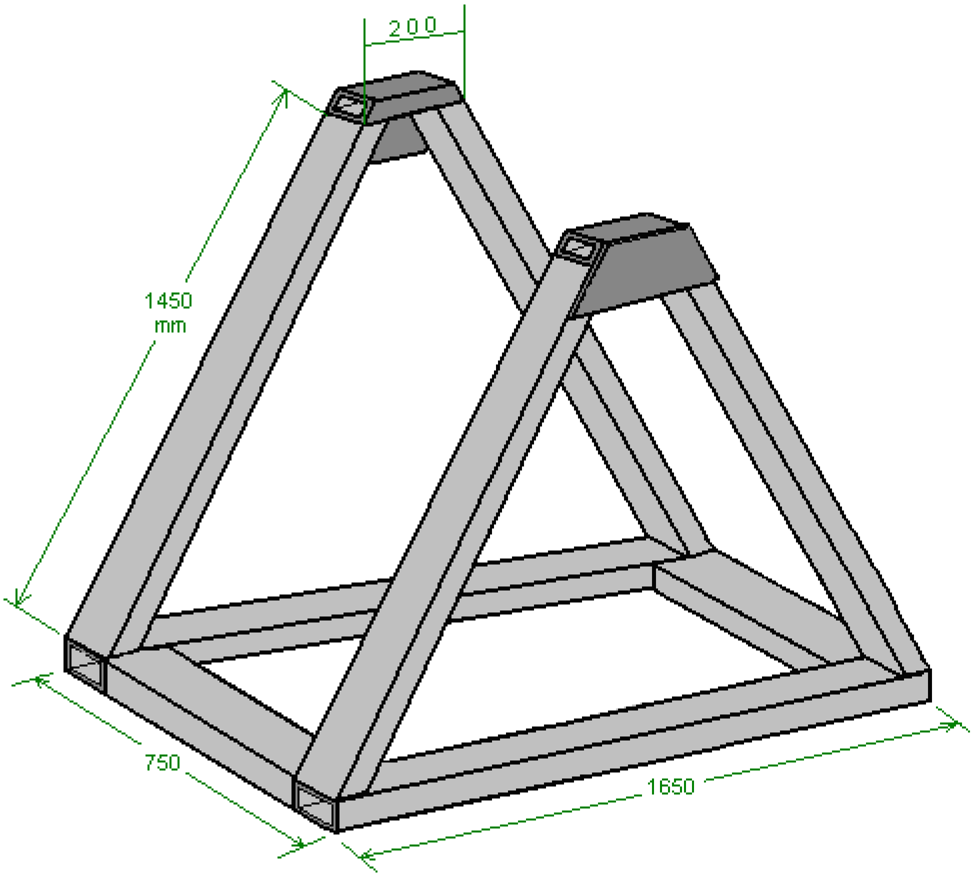
No matter what tool is used, don't rush through the cut but take your time and make a good clean and accurate cut. The disc components can be held together by bolts and/or they can be set into a cohesive whole by using one of the boat building epoxy resins which can be mixed in large volumes and easily spread across the whole face of the components, provided that the workplace temperature does not fall below 5 degrees Centigrade for several hours after the epoxy mix is applied. Other wood glues could be used if the epoxy is considered too expensive.

WEST SYSTEM
206
HARDENER
WEST SYSTEM
105
EPOXY RESIN

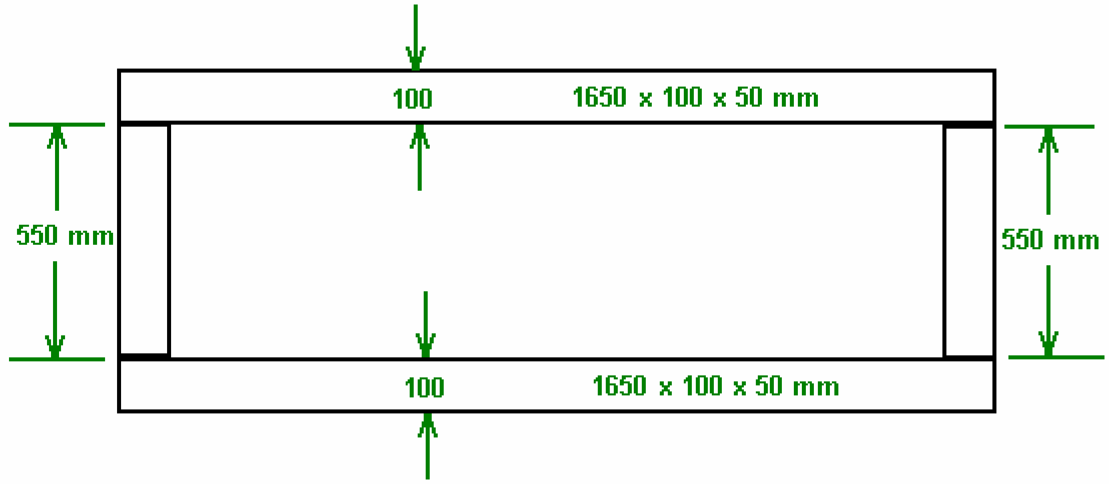
The bearings are placed exactly aligned with the outer disc and secured in place with epoxy resin or other suitable glue for a steel-to-timber strong joint. The glue is applied the whole way around the outer ring of the bearings and that concludes the Flywheel construction, making the equivalent of the metal flywheel first described:



The next step is to build the base support for the generator, and that support is mainly for the large wheel. If you are working in steel, then it is constructed by welding together some pieces of box steel to form a shape like this:

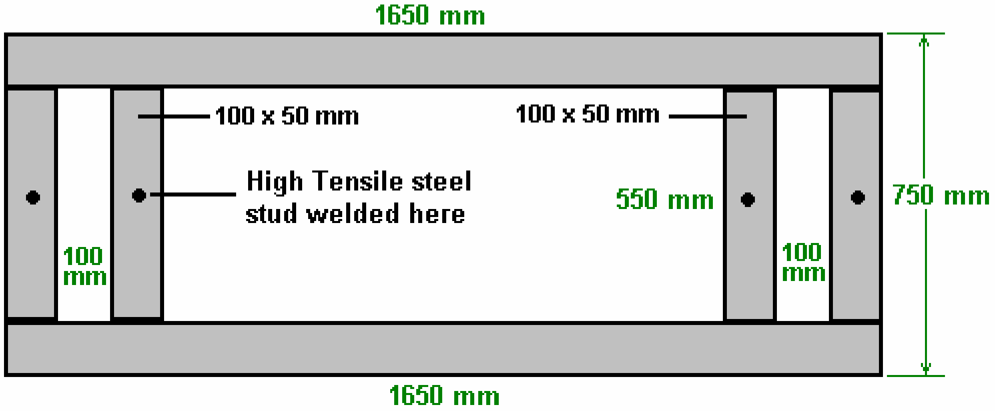


If working in timber, keep the same overall size of the components (which are solid timber) and be sure to make the two triangular parts very robust with both epoxy and screw attachments for each join. Otherwise, we start by constructing the base using steel “channel” which is a box section material. The size we want is 100 x 50 mm which is (4-inch x 2-inch as there are 25.4 mm in one inch) and we join two 1650 mm long pieces using two 550 mm long pieces to form the base rectangle:



It is not at all easy to take a welded joint apart, even if that welded joint took only a tenth of a second to make, so it pays to get the job done exactly right every time. Place the two pieces to be joined on a flat surface such as concrete (which is not flammable) and get them in exactly the right position. Then weight them down so that they can't move. Then, and only then, weld them together. Probably the most difficult thing about welding is the fact that it is very hot and the heat makes the metal expand. I suggest therefore, that you make a short weld of perhaps 20 to 25 mm long and then stop and wait for that weld to cool down before welding the next short length. If you have a long weld to do, then weld the start. Let it cool. Then weld the end. Let it cool. Then weld the middle and let it cool. Those welds hold the piece securely against further movement as you gradually fill in the distance between those first three welds with short welds, letting each one cool before making the next weld and spacing those welds apart as much as possible to let each weld area cool as much as possible between welds.

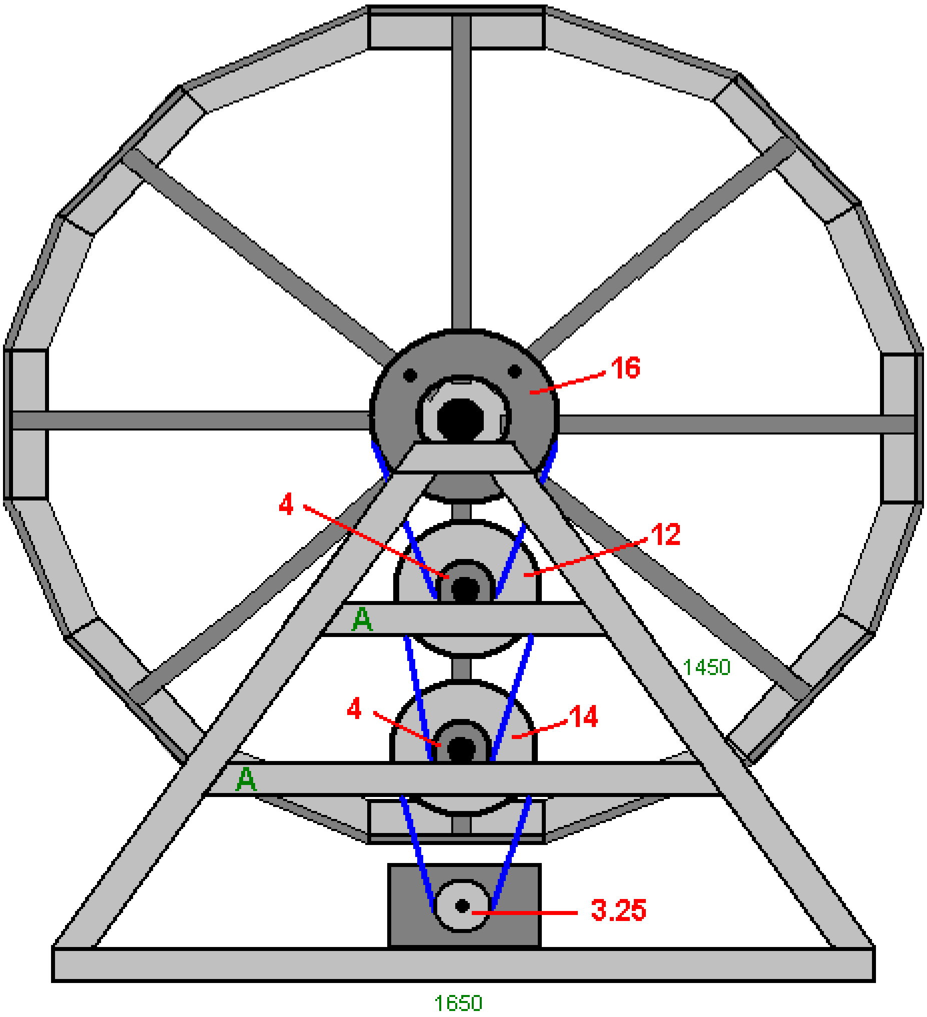
When the main base is completed, two additional pieces 550 x 100 x 50 mm are welded in place as shown here:



Also, a strong threaded stud is welded in the middle of each of the cross pieces. A stud is effectively a threaded bolt without a head, and where the head would have been is welded to the base members as shown above. These studs are like those used to attach car wheels and in this application they are there to allow something to be bolted to the base.

One of the things bolted to the base is the alternator. Chas used a “Genelite” 3.5 kilowatt alternator which is a single-phase, 220 volt, 50 Hz unit which needs its shaft to be spun at a nominal 3000 rpm in order to generate the normal mains voltage and frequency. As the flywheel spins at just one revolution per second, Chas uses three V-belt pulleys (shown in blue) to generate the wanted shaft speed on the alternator. In his area, the pulley sizes are specified in inches and he uses 16 inch driving 4 inch. Followed by 12 inch driving 4 inch. Followed by 14 inch driving a 3.25 inch diameter pulley on the alternator shaft. That gives ratios of 4:1, 3:1 and 4.3:1 which combine to drive the alternator shaft at 51.6 revolutions per second which is 3096 rpm.

The large flywheel and pulleys are mounted on the support frame and look like this:

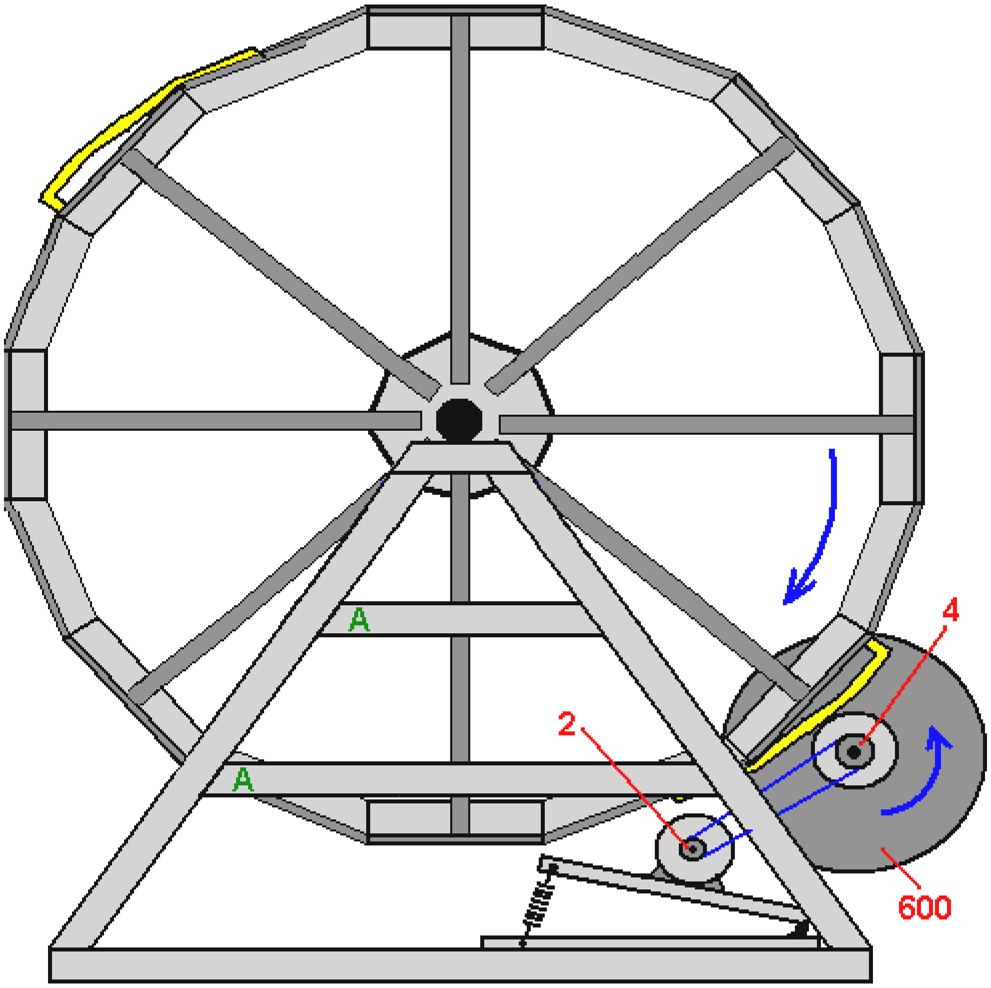


To support the intermediate pulley axles, additional support members "A" are added to the inside of the frame to support the additional bearings or "pillow blocks" which form the mounting for the additional pulley axles. For Chas' design and the solid wood version where the main flywheel axle is stationary and the flywheel rotates around that stationary axle, the largest pulley (16 inch diameter in Imperial units or 450 mm diameter in metric units) is adapted so that it doesn't touch the axle and is bolted directly to the flywheel, using spacers to align it with the pulley train below it. The pulley is larger than the flywheel hub and so needs to be attached to four of the spokes.

In the version where the 50 mm diameter axle rotates, the largest pulley is available with a 50 mm central boss and so it can be attached directly to the axle in the required position. Where your pulleys are bought depends on where you live. One such supplier is http://www.bearingstation.co.uk/Products/Pulleys/V_Pulleys/SPA_V_Pulley but there are many similar suppliers around the world.

While the diagram above shows the gear train from the flywheel to the generator in a logical vertical alignment, there is no particular need to do that and the drive train can zig-zag if you wish. As long as the flywheel continues to rotate at its one rotation per second, the generator shaft will spin at 3000 rpm (or perhaps slightly faster than that) and the system will output continuous AC electricity which can operate power tools, lights, heaters, refrigerators, etc. This is a continuous system which can operate at all times, day and night. It can charge a bank of lead-acid batteries, but lead-acid batteries are only 50% efficient and so they waste half of the power that you feed into them, so if you feed 10 amps into your lead-acid battery for 10 hours, your battery will only be able to provide 5 amps for 10 hours, and there seems little point in throwing away half of your generated power, quite apart from the fact that the batteries are heavy, expensive and will need to be replaced every four years or so.

So, we need to keep the flywheel spinning and do that with as little power as necessary. In this design, the main flywheel is made to spin by a rubber covered drum pressing briefly against a rubber covered ramp attached to the main flywheel. As we want to keep the flywheel balanced, we actually attach two ramps to it, spaced out so that they are exactly opposite each other, that is, at 180 degrees apart. That means that the large flywheel receives two thrusts per revolution. The arrangement looks like this:



This diagram shows only one drive motor and while the system will work with one motor it is more powerful with two and so an identical unit can be mounted on the left hand side of the support frame. The motor used by Chas is the Australian built CMG one-horsepower AC mains motor which runs on 240 volts 50 Hz, at 1410 rpm, drawing 750 watts under full load and has a 5/8 inch (16 mm) drive shaft which has a 2-inch diameter pulley mounted on it, connected to a 4-inch diameter pulley on the small flywheel. The motor is mounted on a hinged plate with a spring pulling the plate away from the small flywheel. The main reason for this is to allow the small 600 mm diameter flywheel with its 180 mm diameter rubber covered drive cylinder, to move outwards slightly when it comes in contact with the drive ramp attached to the large flywheel. This is effectively an automatically adjusting arrangement

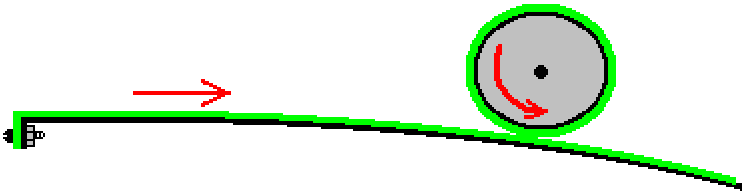
As you can see from the diagram, the main flywheel rotates clockwise while the 600 mm diameter flywheel rotates counter clockwise. If you wish that they went around in the other direction, then just walk around to the other side of the generator and your wish is magically granted with the main flywheel going counter clockwise and the small flywheel going clockwise !!

The current drawn by the drive motor (or motors) is far less than their full working load current draw of 4.5 amps, probably around 2.2 amps. Chas also reduces the current by switching the supply to the motor and allowing 3 seconds of current flow followed by two seconds with the motor disconnected, where the shaft rotation is driven by the momentum of the small flywheel. Chas achieves this switching by gearing down the movement of the main flywheel to give one rotation in five seconds. While that works, it is a mechanical switch which has one fixed setting and is subject to wear as time goes by. I suggest that there is no gearing down, but instead that the current flow to the motor is controlled electronically, using an ordinary light dimmer switch which is available in powers up to one kilowatt and which allows continuous adjustment of the current so that the most effective current flow for the motor can be set by the turn of a knob and no moving parts are involved.

We come now to the construction of the drive ramps and driving cylinders. Ideally, we would like both to be covered in rubber so that there is good traction and the minimum of noise as the main flywheel is driven around. If you live in an area where there are lots of workshops, you may be able to get these components covered in vulcanised rubber. If no such facilities are available, then perhaps cutting up an old car tyre might be a good alternative. While the temptation is to use your angle grinder with a cutting blade, that is probably not a great idea as the speed of the blade is liable to melt the rubber and make a good deal of mess. So, slower cutting is an advantage and perhaps an ordinary hand saw like this:

might work well when cutting the tyre.

If building in steel, making the curved ramp is not the easiest thing to do. You need a strip of steel which is not thicker than 3 mm and ideally, thinner than that if it needs to be bent into a smooth, even curve. Chas recommends that the ramp is one inch (25 mm) higher than the rim of the large flywheel at the trailing end of the ramp. The idea is that the leading edge of the ramp passes easily underneath the drive roller, but contacts it after a few inches as the flywheel rotates, transferring energy from the small flywheel and its motor to the large flywheel. The rubber strip needs to be attached very securely to the ramp. If possible, epoxy resin covering the whole of the ramp surface and mating with the cleaned and roughened inner surface of the rubber strip should give a good grip. Further strengthening of the bond is given by bolting the rubber to the raised, trailing end of the ramp as that is the point of greatest stress:

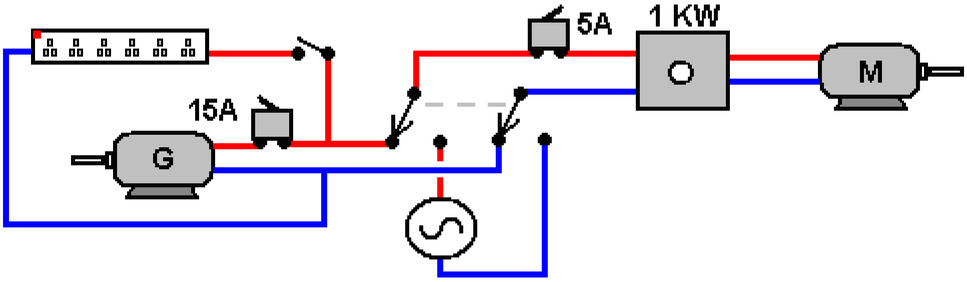


It has been found that the 180 mm diameter rubber covered drive wheel works better if it is filled with lead. The curved drive strip has an optimum length of 900 mm determined by experimentation, and two bracing blocks are glued in position at the one-third and two-thirds of the length, to prevent any flexing of the strip when the roller is pressed against the strip. When the unit is completed, the alternator is disconnected electrically in order to make it the minimum possible drag on the flywheel and then the small flywheel or flywheels are got up to speed, either by connecting to the mains or by connecting to an inverter powered by a battery. Then the large flywheel is spun in the correct direction by hand and when the large flywheel gets up to speed, the alternator output is switched so as to power the motors and the other electrical equipment which is to be powered by the system.

Chas has a preference for using two drive motors and four evenly spaced drive strips. This gives a balanced flywheel and a more powerful thrust to the main flywheel four times per revolution, unless you wish to consider each thrust as a separate item, in which case, there are 8 thrusts per revolution. However, two thrust strips and a single motor will certainly generate excess power and the system can be upgraded with extra strips and/or a second motor when there is finance for that type of upgrade. The 600 mm diameter flywheels weigh 109 pounds (50 Kg) each with most of the weight positioned around the rim.

It is quite possible that if the alternator output power is connected to the drive motors and no other load, that spinning the main flywheel by hand would be sufficient to get the system running. An alternator is very much like a bicycle dynamo in operation as electricity is produced by moving coils through magnetic fields. In the case of an AC alternator used here, if the rate of rotation of the alternator drive shaft is lower than expected, then the alternator output voltage will be lower than it is at full speed, but it still can produce considerable voltage. Most drive motors are capable of working with a much lower voltage than they are supposed to have and that means that the drive cylinders can progressively build up the speed of the small flywheels which in turn can help the manual spinning of the main flywheel until the system progressively works up to its full operational speed.

The electrical connections are very simple. The mains connection is fed to the drive motor through a 2-pole, 10 amp, changeover switch so that the supply can be switched from the mains to the generator output when the flywheels are spinning at their normal speed. For additional control of speed, a 1 kilowatt light dimmer switch can be placed between the switch and the motor. Contact breakers should also be used and the generator output should have an On/Off switch as well. This gives an arrangement like this:



In the position shown, the Generator is feeding current to the drive motor "M". The 15-amp circuit breaker protects the generator "G" from a short-circuit anywhere else in the circuit. The 5-amp circuit breaker protects the 1-kilowatt dimmer switch and the Motor "M". With the switch in the other position, the mains (or the output from a battery powered inverter) is fed through to the motor when the system is being started.

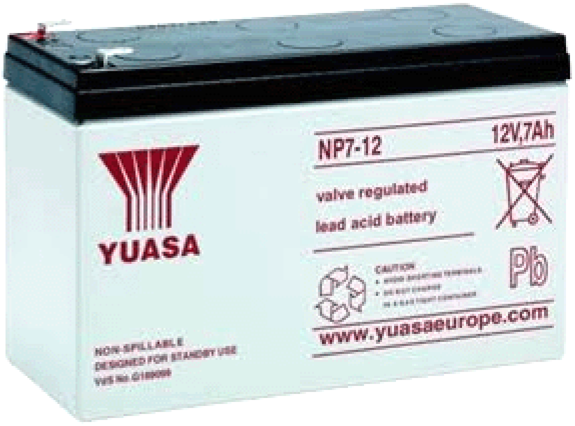
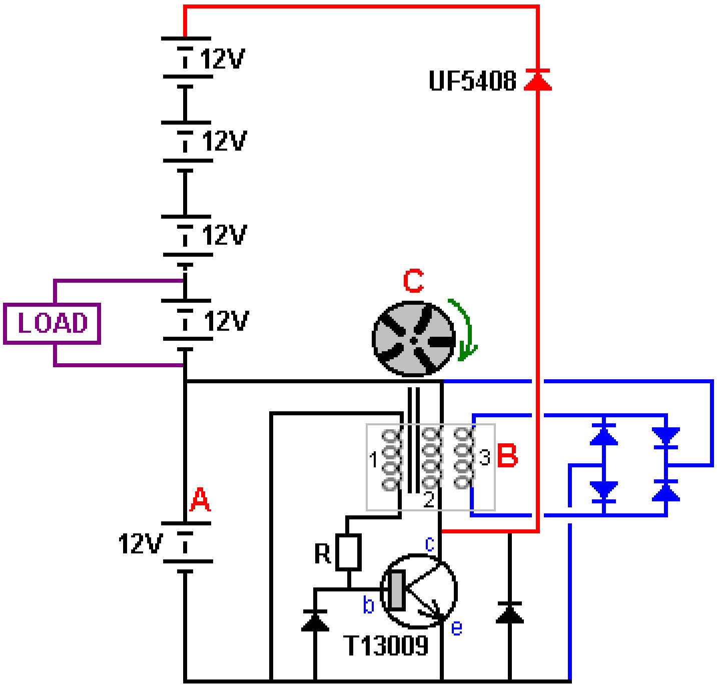
Chapter 21: A Small Self-Powered Generator

A free-energy developer working in South Africa where it is difficult to find electronic components, has very kindly shared the details of his compact self-powered generator so that you can build one if you choose to do so. Using a small inverter, the output of the prototype is 40 watts at mains voltage and frequency and the generator is a small table-top unit which is not difficult to build. The generator uses five small 12-volt 7 Amp-Hour lead-acid batteries like this:



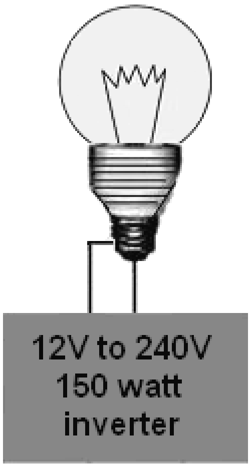
While this sounds like a lot of batteries, bear in mind that this is a generator which has a continuous electrical output, day and night and the batteries never have to be charged – a bit like a solar panel which works at night as well as during the day. Even if you are not familiar with electronics circuit diagrams (chapter 12 can fix that for you if you want), please try to follow along as we run through the circuit diagram and explain how the generator works. This is the circuit diagram:



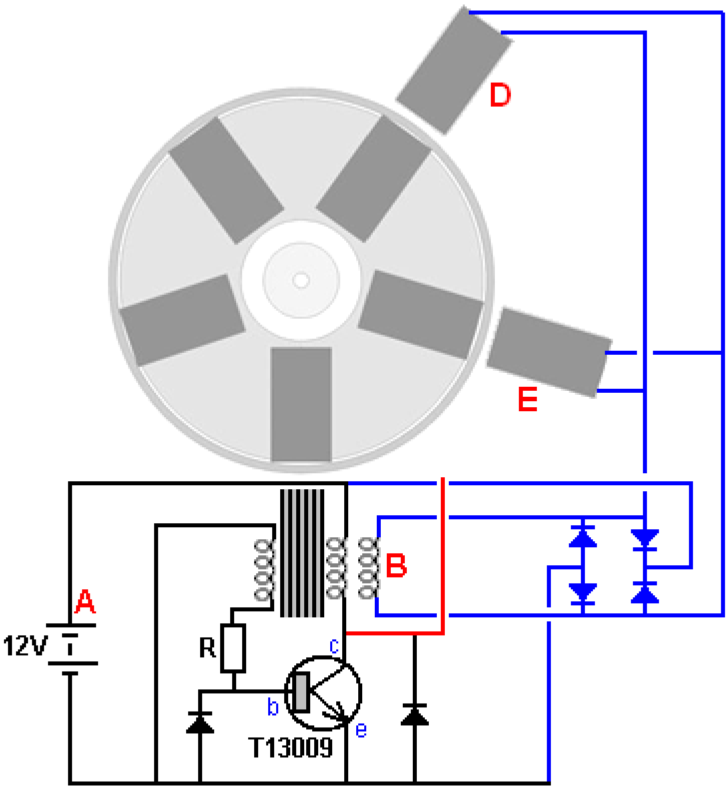
The battery marked “A” powers the circuit. A rotor “C”, containing five magnets is moved so that one of the magnets passes near the coils. The coils set “B” has three specially-wound coils and the magnet moving past those three coils generates a small current in coil number “1” which then flows through the resistor “R” and into the base of the transistor, causing it to switch on. The power flowing through the transistor coil “2” causes it to become a magnet and that pushes the rotor disc “C” on its way, keeping the rotor spinning. It also induces a current in the winding “3” and that current is rectified by the blue diodes and passed back to charge battery “A”, replacing the current drawn from that battery.

When the magnet in rotor “C” passes away from the coils, the transistor switches off, moving its collector voltage very quickly up to the +12 Volt line, starving coil “2” of current. Because of the way that coils are, the coil drags the collector voltage on up and it would reach 200 volts or more if it were not connected through the red diode to all five batteries which are connected in one long chain. The batteries will have a combined voltage of just over 60 volts (which is why a powerful, fast-switching, high-voltage T13009 transistor is being used. As the collector voltage passes the voltage of the battery chain the red diode starts conducting, passing the available energy in the coil into the battery chain. That current pulse passes through all five batteries, charging all of them. The higher voltage caused by so many batteries means that higher power is fed into all the batteries from coil “2”. Loosely speaking, that is the generator design.

In the prototype, the load for long-term testing was a twelve volt 150-watt inverter powering a 40-watt mains light bulb:

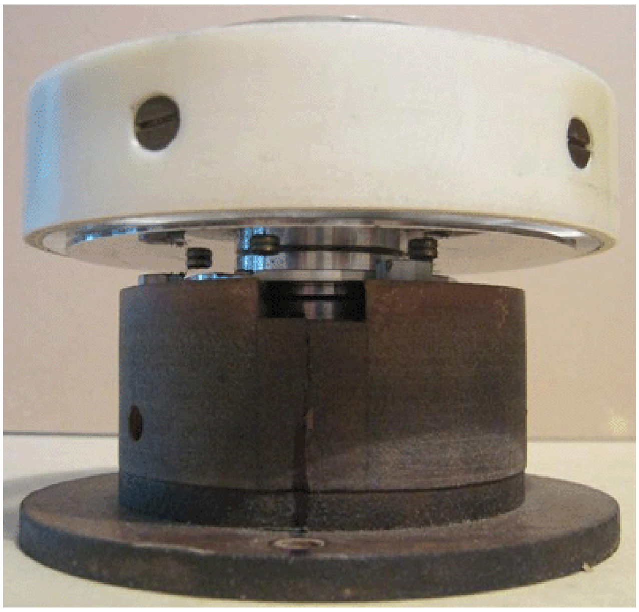


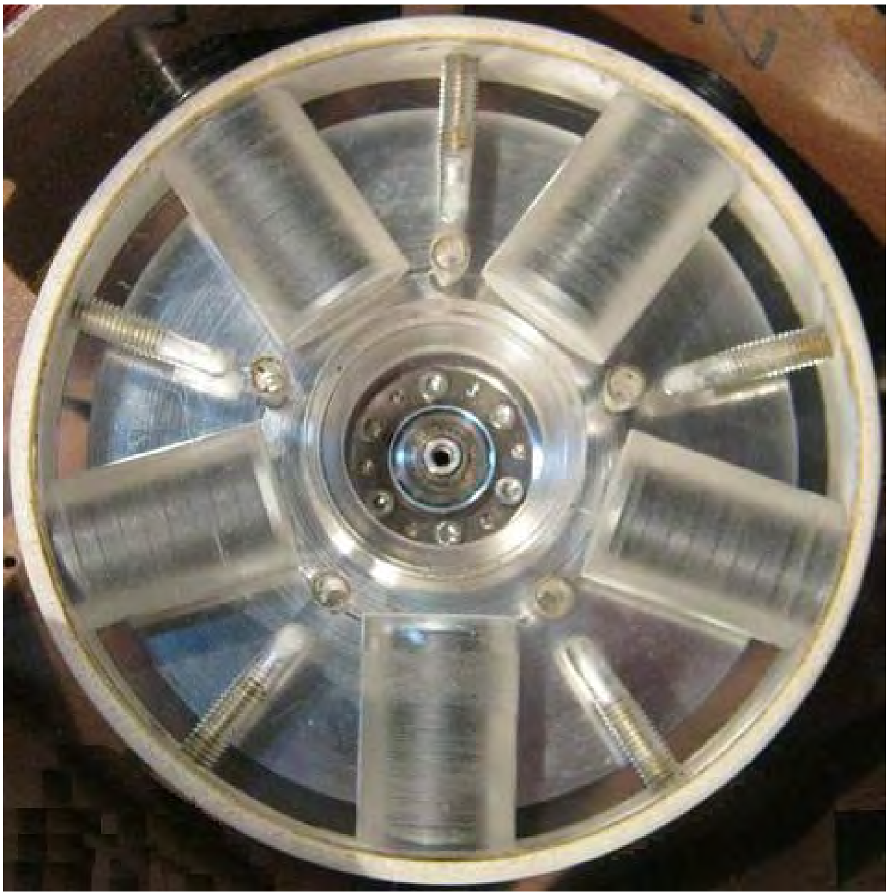
The basic design shown above was then modified by the addition of two additional pick-up coils:



Coils “B”, “D” and “E” are all triggered at the same time by three different magnets. The electrical energy produced in all three coils is passed to the four blue diodes to produce a DC power supply which is used to charge battery “A” which powers the circuit. That additional input to the drive battery and the addition of two more drive coils to the stator, makes the system operate securely as self-powered, maintaining the voltage of battery “A” indefinitely.

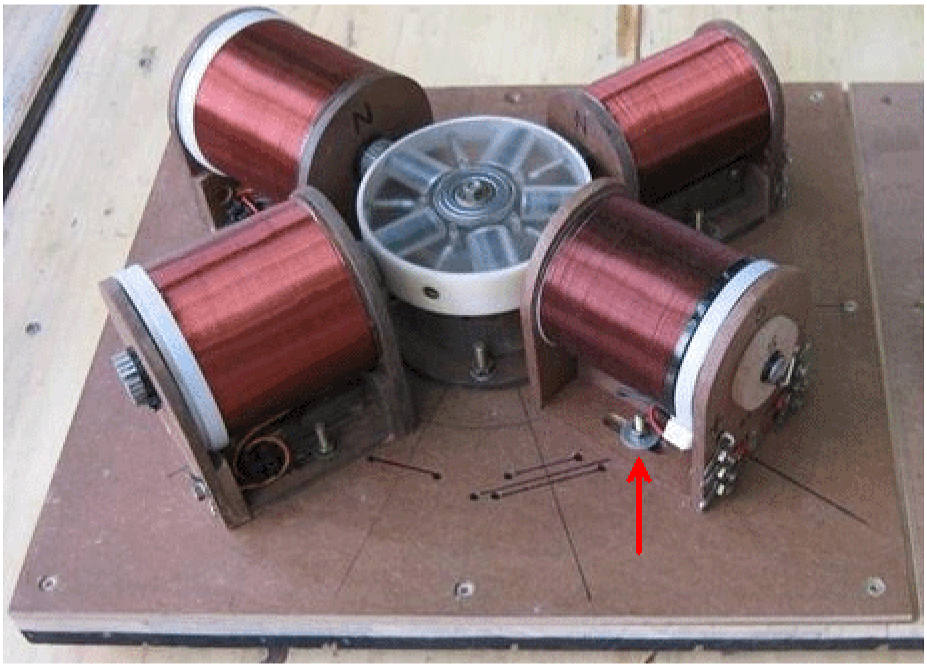
The only moving part of this system is the rotor which is 110 mm in diameter and is a 25 mm thick acrylic disc mounted on a bearing taken from an old computer hard disc drive. The arrangement looks like this:





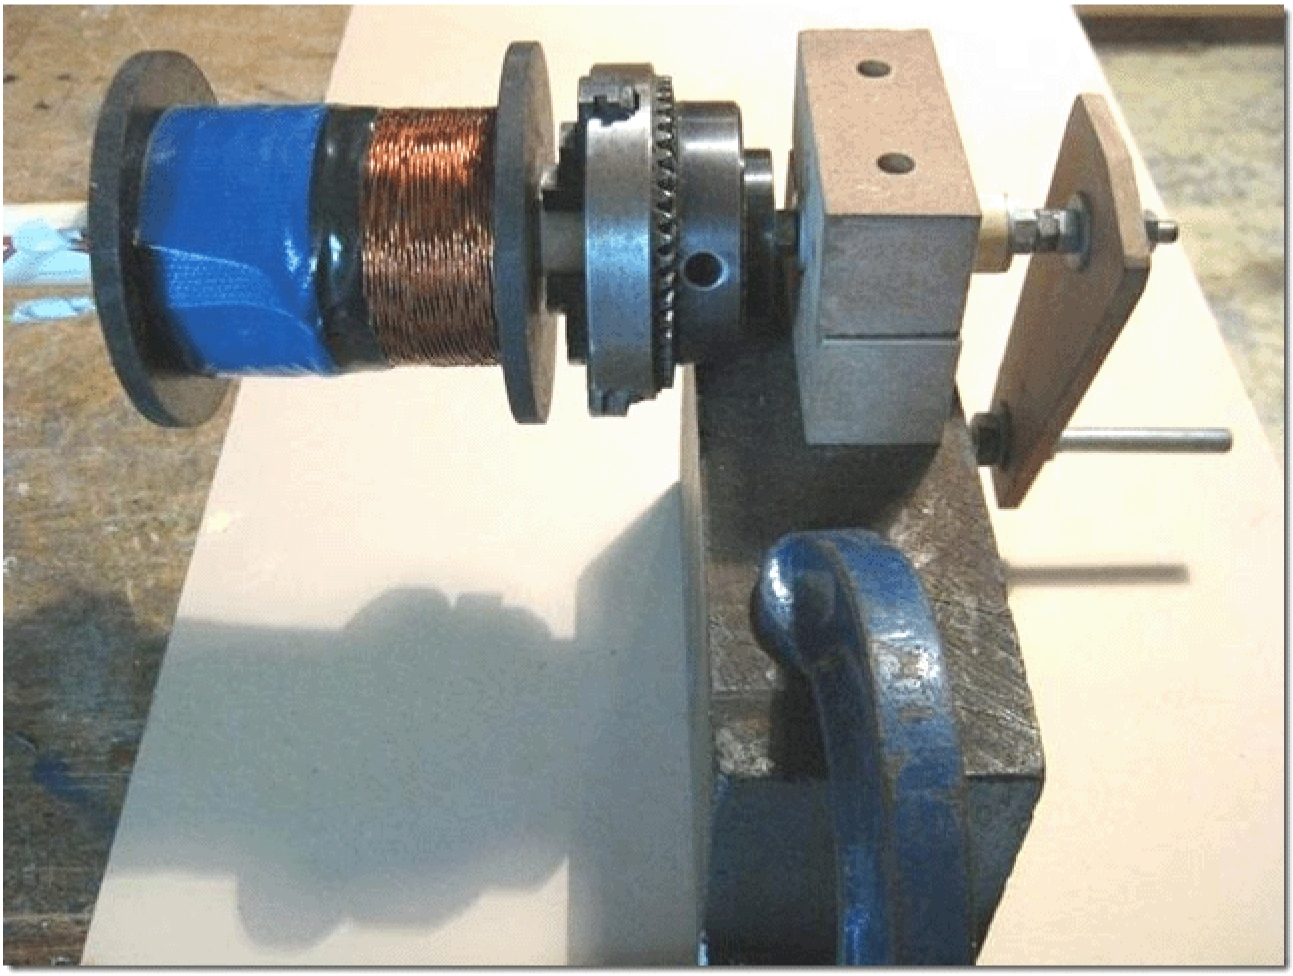
In the pictures, the disc looks to be hollow but in actual fact it is solid, very clear plastic. The disc has been drilled at five evenly spaced points around the circumference, that is, at 72 degree intervals. The five main holes drilled in the disc are to take the magnets which are sets of nine circular ferrite magnets, each 20 mm in diameter and 3 mm thick, making each stack of magnets 27 mm long and 20 mm in diameter. The magnet stacks are positioned so that their North poles face outwards. When the magnets have been installed, the rotor is placed inside a strip of plastic pipe which prevents the magnets escaping when the disc is spun rapidly. The plastic pipe is secured to the rotor using five bolts with countersunk heads.

The gap between the rotor and the coils can be set as anything from 1 mm to 10 mm as the coils have slotted mounts as can be seen from this picture of an earlier version of the generator:



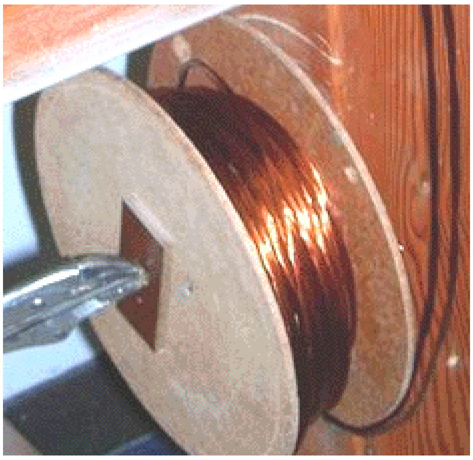
Notice the way that the coil mounts allow the distance between the coils and the rotor to be changed. The working gap between the rotor and the coils can be adjusted so that the performance can be maximised by finding the most effective gap.

The spools of the coils are 80 mm long and the ends are 72 mm in diameter. The centre shaft of each coil is made of a length of plastic pipe with a 20 mm outer diameter and an inner diameter of 16 mm. giving a wall thickness of 2 mm. After being wound, that inner diameter is filled with a series of welding rods with their welding coating removed, and which are then encased in polyester resin although a solid bar of soft iron is a good alternative:



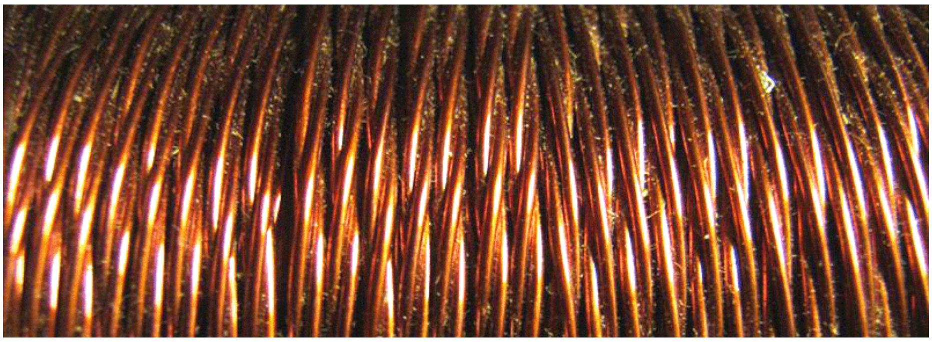
The three strands of wire which form coils “1”, “2” and “3” are 0.7 mm diameter wire and they are twisted together to become a “Litz” wire before being wound into the coil “B”. This produces a much thicker composite wire strand which is easy to wind accurately on to the spool. The winder shown above uses a chuck to grip the coil core for winding, but any simple winder will work well.

The developer does the Litzing by stretching out three strands of wire, each coming from a separate 500 gram reel of wire. The three strands are clamped at each end with the wires touching each other at each end and with three metres between the clamps. Then, the wires are clamped in the middle and 80 turns applied to the middle. That gives 80 turns for each of the two 1.5 metre lengths held between the clamps. The twisted wire is wound on to a makeshift reel to keep it tidy as this twisting has to be repeated 46 more times as the entire contents of the reels of wire will be needed for this one composite coil:



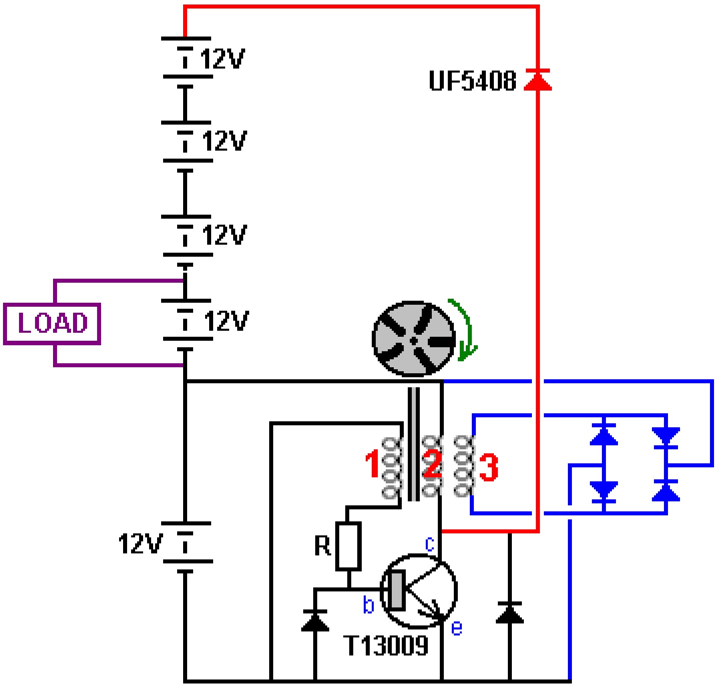
The next 3 metres of the three wires is now clamped and 80 turns applied to the central point, but this time the turns are applied in the opposite direction. Still the same 80 turns, but if the last length was ‘clockwise’ then this stretch of wire will be turned ‘counter-clockwise’. This alternation of direction gives a finished set of twisted wires where the direction of twist reverses every 1.5 metres along the length. That is the way that commercially produced Litz wire is made, but I seriously doubt that the resulting performance is any better than if the direction of wind was never changed and the twisted wire had the same direction of twist along its whole length.

This very nice twisted group of wires is now used to wind the coil. A hole is drilled in one spool flange, right beside the central tube and core, and the start of the wire fed through it. The wire is then bent sharply at 90 degrees and fed around the shaft of the spool to start the winding of the coil. The wire bundle is wound carefully side by side along the length of the spool shaft and there will be 51 turns in each layer and the next layer is wound directly on top of the first layer, moving back towards the start. Make sure that the turns of this second layer sit exactly on top of the turns beneath them. This is easy to do as the wire bundle is thick enough to make positioning very easy. If you prefer, a single thickness of white paper can be placed around the first layer, to make it easier to see the second layer as it is wound. There will be 18 of these layers to complete the coil, which will then weigh 1.5 kilograms and in 2016 prices in the UK, the wire in this coil will cost £45 and the winding looks like this:

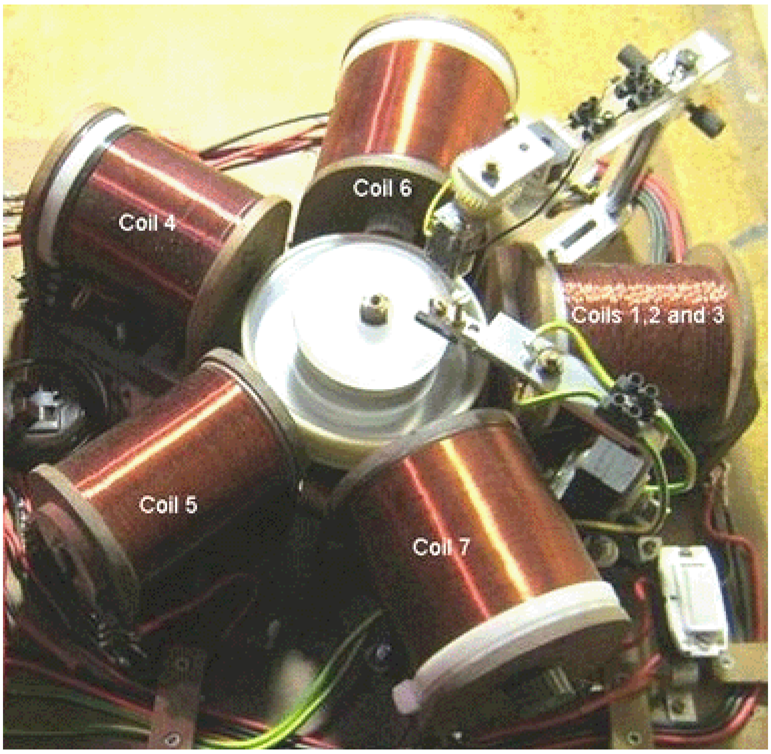


This completed coil now contains three separate coils in very close proximity to each other and that arrangement is excellent when one coil is powered up, for inducing energy in the other two coils. This winding now contains coils 1,2 and 3 of the circuit diagram. There is no need to concern yourself with marking the ends of each strand of wire as a simple ohmmeter will tell you which two ends have a winding between them.

Coil 1 is used as the trigger coil which switches the transistor on at the right instant. Coil 2 is the drive coil which is powered by the transistor, and Coil 3 is the first of the output coils:



Because of the coils which were already to hand during the development of this highly successful system, coils 4 and 5 are simple helical-wound coils which are wired in parallel with drive coil 2. They boost the drive and they are necessary. Coil 4 has a DC resistance of 19 ohms and coil 5 a resistance of 13 ohms. However, investigation is underway at present to determine the best coil combination for this generator and it is probable that the additional coils will be the same as the first coil, coil “B” and that all three coils are connected in the same way and the driving winding in each coil driven by the one powerful, fast transistor. The present arrangement looks like this:

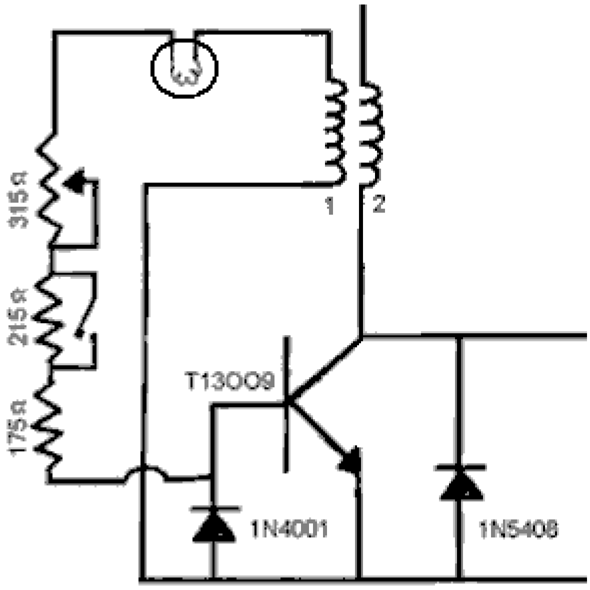


The two gantries can be ignored as they were only for investigating alternative ways of triggering the transistor and they are no longer used.

At this time, coils 6 and 7 (22 ohms each) are extra output coils connected in parallel with output coil 3 which is 3 strands each with 4.2 ohm resistance. They can be air-core or have a solid iron core. Testing indicates that the air-core version works slightly better than having an iron core. These two coils are wound on 22 mm diameter spools and each has 4000 turns of 0.7 mm (AWG # 21 or swg 22) enamel or shellac insulated solid copper wire. All of the coils are wound with this size of wire.

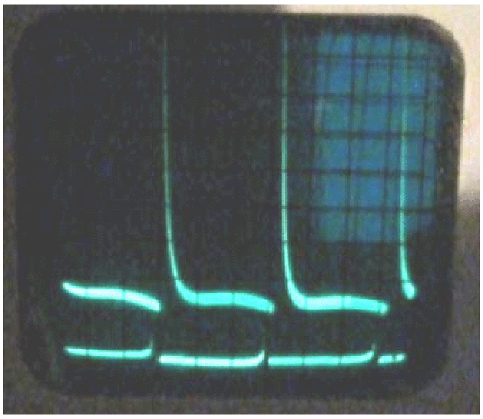
With this coil arrangement, the prototype has run continuously for three weeks, maintaining the drive battery at 12.7 volts all the time. At the end of the three weeks, the system was stopped so that it could be altered and tested with a new configuration. In the configuration shown above, the current flowing from the driving battery into the circuit is 70 milliamps, which at 12.7 volts is an input power of 0.89 watts. The output power is either 40 watts or close to it, which is a COP of 45, not counting the fact that three additional 12V batteries are being charged at the same time. That is very impressive performance for the circuit. However, those three additional batteries could probably sustain identical loads, raising the output to 160 watts or COP=180 without any changes at all, but at this time, that has not been tested and the circuit is undergoing other tests and modifications. Even using a 24V inverter across two of the four batteries should give an enhanced output with 80 watts of usable power.

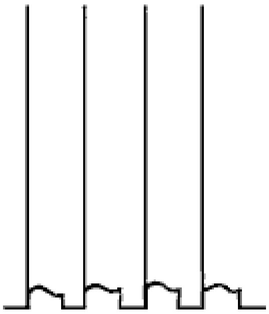
The drive method has been used so often by John Bedini, that the developer decided to try out John’s method of tuning for maximum performance. For that, the transistor’s base resistor shown as “R” in the circuit diagrams was altered to this:



This arrangement allows the value of the base resistor to be adjusted over a wide range, and car's rear light bulb gives a visual indication of the current flow into the transistor. This is an important adjustment and the current flowing into the base of the transistor can be very high. For that reason, the resistors shown need to be heavy duty wire wound types and they get very hot until the optimum adjustment is found. At that "sweet spot" as it is known, the current flowing into the base of the transistor reaches its minimum value and the magnetic drive in the coil group reaches its maximum value, and at that most efficient adjustment, the resistors and transistor become cool and stay that way continuously afterwards.

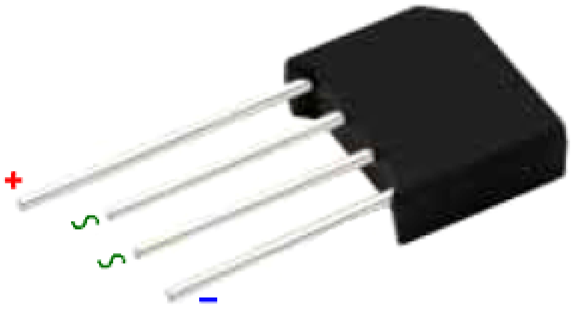
For people already familiar with electronic circuits, the waveform produced by the magnets spinning round in the rotor is the classical battery-charging pulse waveform which looks like this:



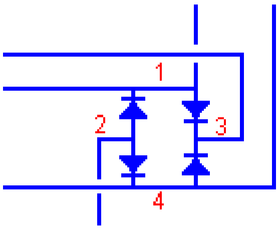


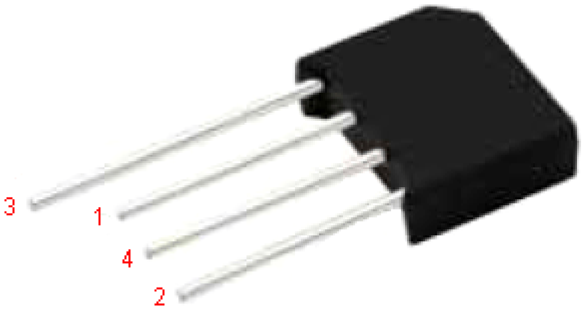
Spiked high voltage output
with low current

The four blue diodes shown in the circuit diagram are contained in a single plastic package as just one component called a "diode bridge". This particular one has the reference number RS405L which can handle voltages up to 600 volts and a constant current of 4 amps. It can also handle short current surges up to 200 amps which might be significant in this circuit with its very sharp charging voltage pulses. The component looks like this:

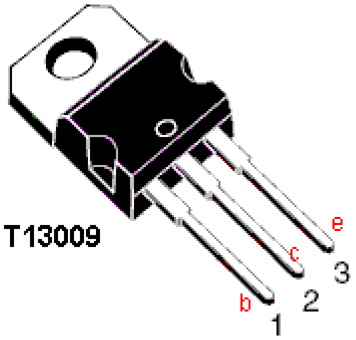


It is connected into the circuit like this:





The other major component in the circuit is the transistor which has the reference number T13009. It looks like this:



This is a fast switching transistor able to handle 400 volts and 12 amps of continuous current or 24 amps in brief pulses. The base current can be up to a massive 6 amps, power dissipation 100 watts and a current gain probably between 20 and 40 in this circuit.

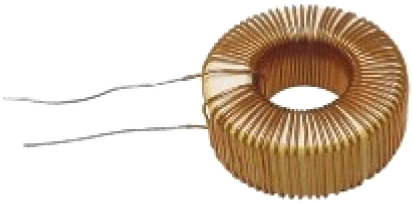
Let me stress that the unit described above is self-powered, drawing its energy from the surrounding environment and as shown it outputs 40 watts of power continuously day and night, day after day. To confirm this, the prototype was run continuously for three weeks. In common with almost all inventors or developers, there is a major inclination to experiment further, and so that three weeks shows remarkable restraint on the part of the developer. If you want to build a replication and don't have any friends who know electronics and so could help, then a tutorial on the details of how to build these things is available as a free download from:
http://www.free-energy-info.com/Chapter12.pdf and it shows methods of construction and explains what you need to know in simple terms.

The description of this self-powered generator is now complete and built as described, it is a genuine self-powered device which you can replicate and use. The development and refinement continues and will be shown here when the circuit has been optimised.

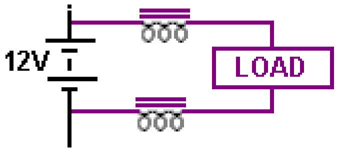
======================

While further investigation continues on the excellent design described above, here are some suggestions and comments from me. Please understand clearly that these are merely my comments which have not been tested out on the build above. In other words, these are my suggestions and are generally **untested** ideas which can safely be ignored. However, there may be some ideas here which you might feel are worth investigating.

Firstly, the load as well as the batteries, receives the pulsing output from the circuit. That may be beneficial, allowing additional output power. However, it is more normal practice to use one or two chokes to protect the load from those voltage spikes. These chokes can be just simple turns of wire on an iron core or they could be commercially available chokes. The one shown here, which has only 48 turns of wire, can handle continuous currents of up to 10 amps:

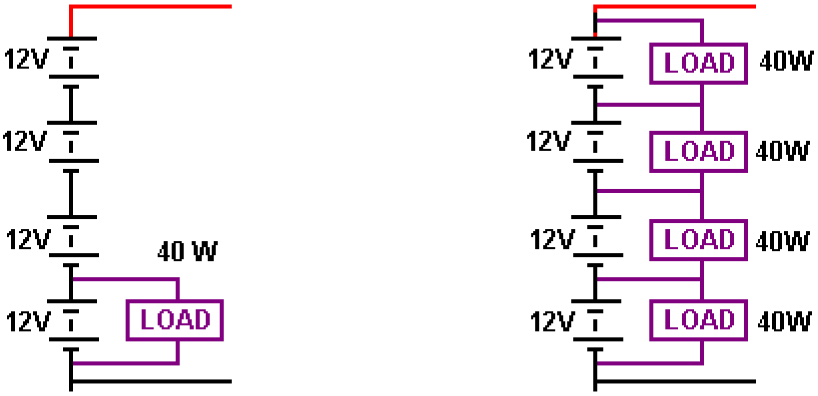


The load could be buffered from the spikes like this:

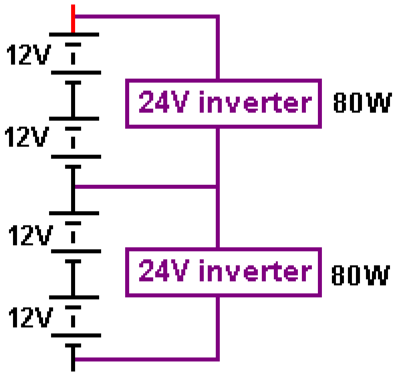


This arrangement allows the voltage spikes to flow through the battery chain but opposes the spikes when they flow towards the load. The “LOAD” shown in purple can be whatever low-current equipment you want, such as a fan, a mobile phone charger, a radio, an LED light, a small inverter, or whatever. Forty watts doesn’t sound like much, but my workspace is very brightly lit with 39 watts of LED lighting which has the equivalent light output of three 100-watt mains-powered incandescent bulbs

Also, remember that the circuit has four identical batteries in that section and if one battery can provide 40 watts of continuous output power, then it seems probable that the other batteries could do the same and that **might** provide a total of 160 watts of continuous free power, giving a COP=180 result:



Also, while it was a 12-volt inverter used with the prototype, that was because it was to hand during the testing. That suggests that if a 24-volt inverter were used:



then because of the doubled input voltage, for the same current draw, 80 watts of mains power should be available from each inverter. Twenty-four volt inverters are quite common as they are used by lorry drivers and lorries (‘trucks’) generally have 24-volt electrical systems.

Nowadays, there is a very wide range of 12V equipment intended for use with a car battery, or even with a 5-volt USB computer socket. For example, LED lighting is very efficient and popular and the 12-volt LED arrays provide very effective lighting. I have tested those LEDs and found some unexpected results, using a lux meter to measure the light output as the human eye is very bad at assessing how bright a light is. What I found was:

Using two LED arrays side by side in a light box, the figures for voltage / current draw / light produced using 1.2-volt NiMh batteries were:

9 batteries 11.7V 206 mA 1133 lux: 2.41 watts 470 lux per watt (the manufacturer's intended performance)

8 batteries 10.4V 124 mA 725 lux 1.29 watts 562 lux per watt

7 batteries 9.1V 66 mA 419 lux 0.60 watts **697** lux per watt (a very realistic performance level)

6 batteries 7.8V 6 mA 43 lux 0.0468 watts 918 lux per watt

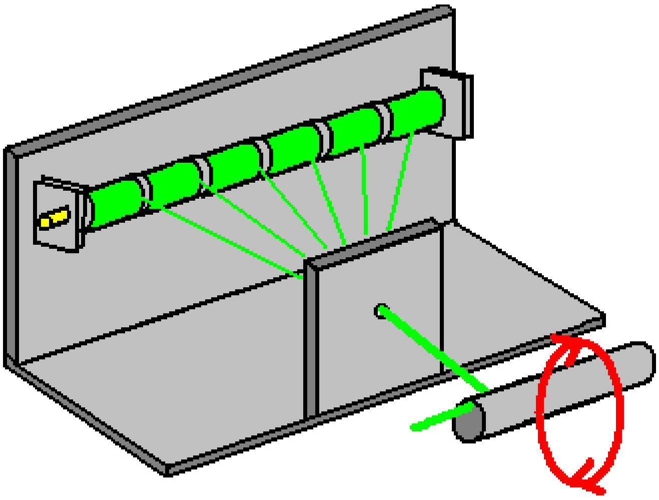
This is very revealing information, showing that one of these LED arrays fed with just 33 milliamps can produce very impressive 210 lux lighting at a wide 160-degree angle of illumination. To put that another way, feeding five LED arrays with 9 volts, generates a very acceptable 1000-lux lighting level for just 165 milliamps which is only 1.5 watts. That is spectacular performance.

So, if we wanted to use LED array lighting with this 40-watt generator, we could just use the 4-battery output voltage of about 51.2 volts. If we wanted to use the very acceptable lighting produced around the 9-volt per LED array, due to its less dazzling light, increased LED area and near zero heat generation, then we could use five LED arrays in series, giving each array 10.24 volts and producing about 1725 lux per set of five LED arrays drawing 300 milliamps. Using three sets of five LED arrays, with a massive 5000+ lux, the current draw would be less than 1 amp, or about 30% of the available power.

These LED arrays look like this:

and come in two different types, one called "day white" or "cool white" with a wavelength of around 5500K to 6500K and a type called "warm" with a frequency of about 2700K to 3200K. You can mix these so that you get both frequency ranges and my preference is for about one third of the units being the so-called "warm" variety. Lighting this intense, needs a cover of frosted plastic which is light, protective and which spreads the light out to an even less concentrated illumination.

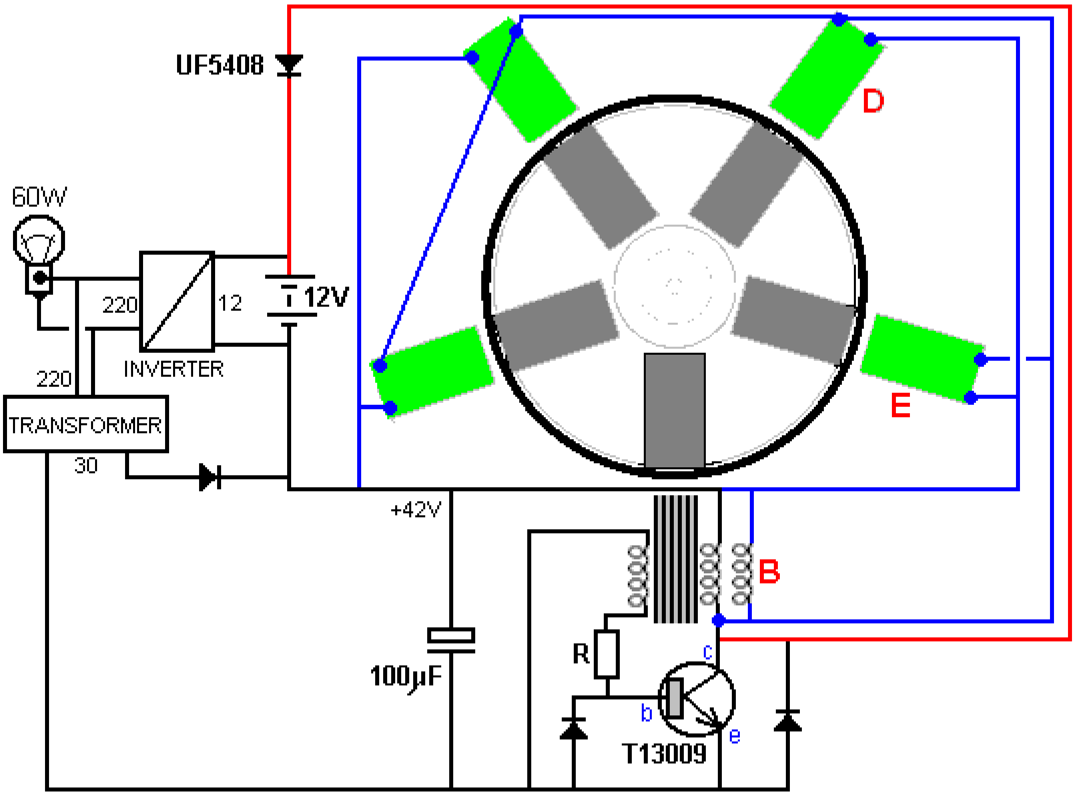
One other point concerns the production of the Litz winding of the wire strands before the coil is wound with the Litzed wire. The developers method of clamping 3-metre lengths of wire and twisting those lengths individually works very well but is rather tedious to do. I would suggest a very simple arrangement which might work more easily:



The idea here is that the reels of wire are mounted on a simple horizontal bar, shown in yellow, and each spool has its wire fed through a hole in a font panel. If the hole is a bit large, then an ordinary plastic spring clamp can be mounted on the board so that its jaws grip the wires just after they come through the hole. The group of wires passes through a small hole drilled near the end of the coil tube and then the tube is rotated (using both hands to get a continuous rotation) to twist the wires into a Litz bundle. When sufficient turns have united the wires into a spiral, the coil tube is rotated to form the coil. Then, another length of the wires is pulled through and the next section of wire is Litzed in the same way and the coil winding continued. The length of wires pulled through is a matter of personal choice, but I would suggest perhaps 300 mm. If desired, a simple spring clamp can be mounted on the coils side of the outlet board, to hold the wires against the winding and twisting. I would suggest that the coil former is rotated so that the wire bundle feeds on to the top of the coil former. That is the easiest to see and control when winding and it is called “counter-clockwise” winding or just “CCW”.

The T13009 transistor is not readily available in some parts of the world. If you have to use a substitute, then its switching speed, voltage rating and current rating rare probably the most important factors to match. The switching speed is difficult to assess but after a 2.5 microsecond delay, the switch off time is 110 nanoseconds. The voltage rating is 400V (although that is probably not used in this application with its 60V load, and the current rating is 12 amps continuous and 24 amps for pulses, it has a 100 watt dissipation rating. Other manufacturers use different designations and it is likely that your local supplier may call this transistor the MJE13009.

Again, our thanks go to the developer for freely sharing this most important circuit which he developed and for his future modifications, the first of which is shown here:



In this arrangement, coil “B” is also pulsed by the transistor and the output from the coils around the rotor is now directed to the output inverter. The drive battery has been eliminated and a low-power 30V transformer and diode run from the inverter output as replaces it. Spinning the rotor generates sufficient charge on the capacitor to get the system running without a battery. The output power has now risen to 60 watts which is a 50% improvement. The three 12-volt batteries have also been eliminated, and the circuit can run with just one battery. Continuous power output from a single battery which never needs to be recharged is a very satisfactory situation.

Chapter 22: Health

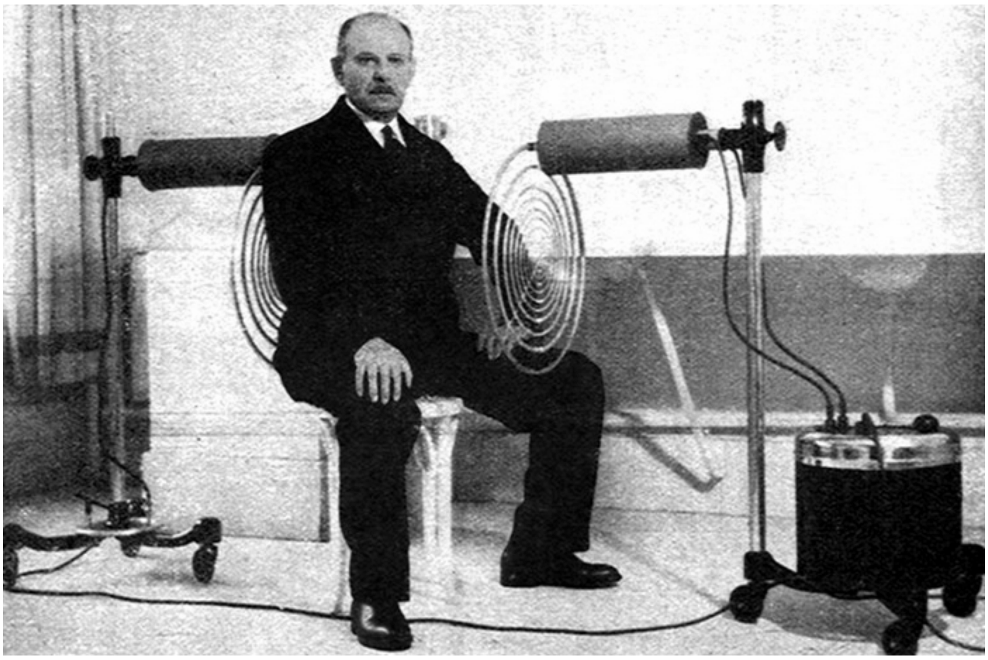
There are a number of things which have a profound effect on the health of any person. There are the obvious things like getting adequate sleep, adequate exercise, adequate diet including a wide range of vitamins and minerals. Most people are already aware of these things.

Hulda Clark states that illness is caused by either absorbing poisons or by becoming infested by one or more of a wide range of destructive bugs and she produced a book covering how to deal with these harmful things: http://www.free-energy-info.com/Hulda2.pdf and another book dealing specifically with treating cancers: http://www.free-energy-info.co.uk/Hulda.pdf.

Bob Beck has also been very effective in dealing with illness, including those illnesses which conventional (pharmaceutical-based) medicine cannot cure. Bob recommends the use of colloidal silver http://www.free-energy-devices.com/Silver.pdf and electronic pulsing at low frequency of about 4 pulses per second http://www.free-energy-info.tuks.nl/Beck.pdf and constructional help can be found at http://www.free-energy-info.com/BeckBuild.pdf.

Both Hulda Clark and Bob Beck have helped many people overcome physical problems. However, around 1920, Georges Lakhovsky, a Russian, presented a very advanced system which is probably the most powerful medical system to date.

The Lakhovsky system is based on the fact that every cell in a living body, vibrates at its own particular frequency and that cells which are not in good health have weak vibrations. Lakhovsky deals with this by sitting his patient in a mild electronic field which vibrates over a very wide range of frequencies. That vibrating field is very beneficial for the patient, as it reinforces the strength of the cells in the body, increasing their strength of vibration and so raising their level of health. There is no contact between the equipment and the patient, and the treatment can deal with all sorts of illnesses. At time of writing I am not aware of any correctly-built, ready-made Lakhovsky oscillator being offered for sale. However, it is perfectly possible to make one of your own and that is what the remainder of this chapter is about. Just to get it clear in your mind, the treatment involves sitting in a harmless electronic field as you can see Lakhovsky doing here:



An American contributor who prefers to remain anonymous, has kindly agreed to share the details of his successful replication of a Lakhovsky wide-range oscillator. His design has been independently replicated by eighteen other people and his own unit has been in regular use for two years now. He says:

Using my Lakhovsky machine I never get sick or even get a cold any more. I use it for fifteen minutes once very four days. I will not bore you with Georges Lakhovsky's life story. There is a fair amount of information on the internet that you can search to find out more about the man. Let me tell you what I think of him, how I came to know him and his work, and why I think he is a “bigger than life” figure.

Lakhovsky was born in 1870 in Russia. He lived in France and then in 1940 he moved to America but having great knowledge and experience, he was welcomed by Dr Disraeli Kobak. Subsequently, Dr Kobak used Lakhovsky's machine to treat thousands of patients who had a wide range of diseases.

Lakhovsky died in a car accident in 1942. He was 73 years old. His son took over his work with Dr Kobak. Lakhovsky believed that cells are small Oscillatory Circuits, emitting ultra short electromagnetic waves. He has shown that no living thing is without cells, and those cells act like a radio formed by oscillating circuits.

In 1998 I purchased a book written by Georges Lakhovsky. The book is entitled "The Secret of Life". I still own that book and I would never sell it. It changed my view of the human body and how it works.... So, I started to collect anything about his work, I wanted to build his Multiple Wave Oscillator machine 20 years ago, but there was just not enough information available at that time.

I had some idea where to start, because of his patent of his early machine, but it was definitely not enough information to invest my time and money at that time. Years passed by while I waited for the right time. I also came to know about the Dotto ring machine but because of lack of information I decided to do nothing about it. As you will see shortly I made the right decision... you can't just guess the Lakhovsky machine! You need to know the facts, to be able to build it properly and safely!

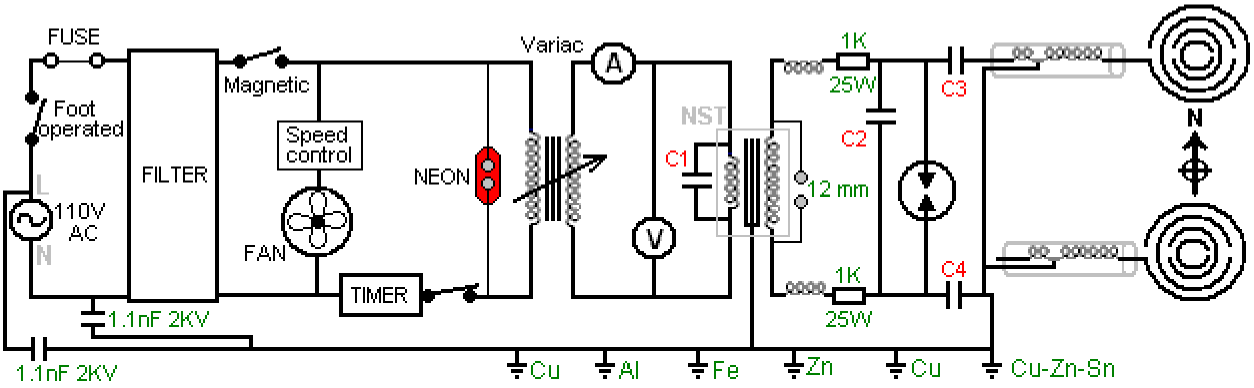
Georges Lakhovsky was a humanitarian, caring individual who saved thousands of lives with his machine. Hundreds of time he treated poor people without charging them a fee. He said one time to a Doctor that to him is not about money and fame, when people came back to him after he healed them the look in their eyes, the gratitude to him was worth more than anything. All he cared about was helping sick people. He was far ahead of his time. He was a genius just like Nicola Tesla was.

Lakhovsky stated that "life is created by radiation, maintained by radiation and destroyed by oscillatory disequilibrium". How Lakhovsky’s machine works is not that difficult to understand. First you need to understand that everything in our universe is vibrating! Tesla said; “If you want to find the secrets of the universe, think in terms of energy, frequency and vibration”. Tesla became a good friend when Georges Lakhovsky asked him to help him to design his coil for his machine. I think the evidence is overwhelming in the machine itself. Some people say that there is Tesla technology hidden in Lakhovsky’s machine.

It is unfortunate that Tesla and Lakhovsky died just few months apart from each other. The biggest problem which Lakhovsky faced was that he had to overcome the fact that the human body made up of over some 200 quintillion cells! Each cell oscillates at its own specific rate, and with its own particular wavelength. So, he had to make an apparatus which is able to generate an electrostatic field with a high number of different frequencies with wavelengths anything from 3 meters to infra-red, that is a frequency from 750kHz through to 3 GHz or even 300 GHz. This is necessary so that every cell could find its own frequency and start vibrating in resonance.

To implement this, he also needed a diffuser antenna with an oscillating circuit connected to it. In 1931 the first Lakhovsky machine was installed in a Paris hospital. In America and in Europe the machine was used very successfully for treating various organic diseases, including cancer.

This is an advanced design and while the circuit diagram shows components as single items, some of them are made up of two or more components as explained in the descriptive text. There is very little scope for alternative components if the equipment is to operate as intended and produce beneficial effects on humans, and even the direction in which the equipment is orientated is a critical factor. However, the design as described here works well and is simple enough for you to build. This is the circuit diagram:



the components are themselves fairly heavy and so are built into a fairly substantial box which itself is physically heavy, and so is mounted on four casters so that it can be wheeled around easily. As the builder is American, his mains supply is 110V AC which is controlled by a foot-operated switch which switch the equipment off instantly if patient chooses. The mains power then passes through a fuse, a filter and a magnetic switch to provide an electronically clean and safe power supply. However, as the circuit creates considerable electronic noise with its spark gap, the filter is primarily there to block signals generated by the circuit from getting back into the mains supply wiring. Similarly, the circuit has a six-rod earth connection located close by and which uses earthing rods of Copper, Brass, Aluminium, Iron and Zinc plated Copper. Please note that your “earth” or “ground” connection has to be your own separate earth connection and the mains earth wire must **not** be used as that would pass interference from the circuit through the common earth wire to other mains users nearby. A cooling fan is run directly from the mains supply and a mechanical manual timer is provided so that the treatment time can be set in advance. A neon lamp is installed to show when the timer is operational.

However, if you are not experienced in electronics, please do not be put off by the circuit diagram as most of the components can be bought ready-made and so the majority of creating the circuit is just a matter of interconnecting commercial components.

What needs to be built are the housing, a few coils (and those are easy to wind, even if you have never wound a coil before), the spark gap which is made from components which can be bought commercially and which is covered in great detail in this document, and the aerials which are also described in detail here.

To encourage you in this, take a look at some of the components which you can use in this project and you will notice that almost everything in the circuit ahead of the spark gap can be bought ready-made:

25/085/21

Whether operating with 110-volts AC mains as in America or with 220-volts AC mains everywhere else, a 770-watt variable transformer known as a “Variac” allows the voltage to the remainder of the circuit to be set manually and a voltmeter and an ammeter are provided to show what the power input is for the remainder of the circuit. Voltmeters, ammeters and capacitors are all available commercially and an eBay search should find the components which you need.

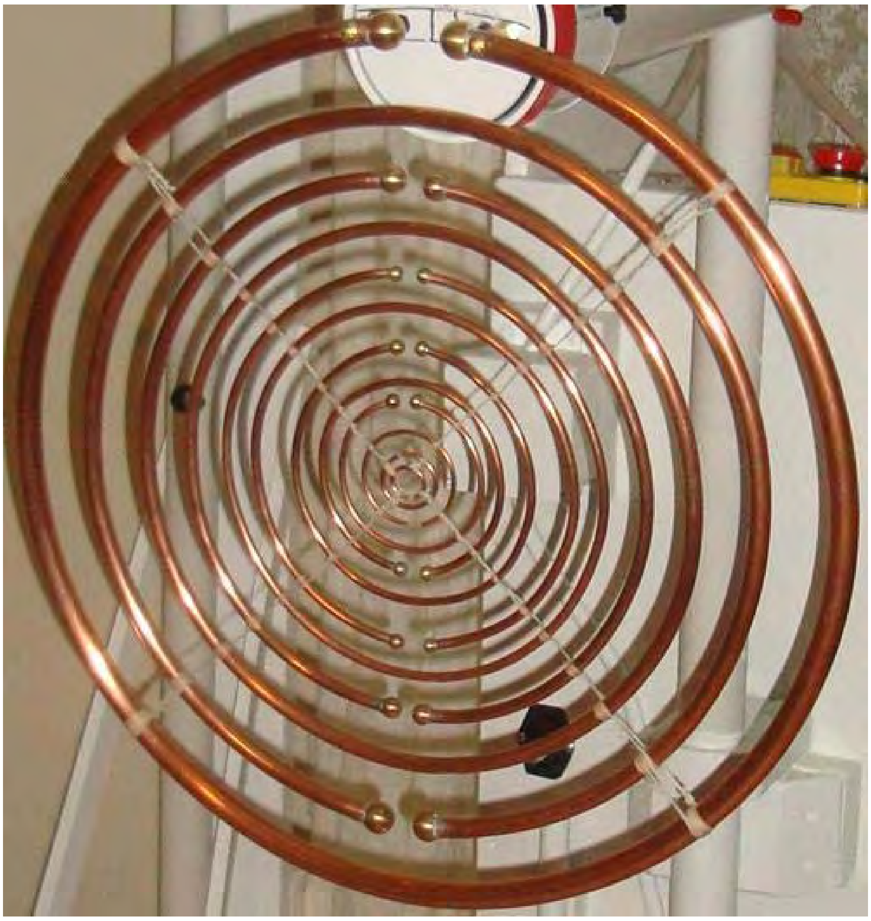
The operational part of the circuit starts with a 12,000V 60mA step-up transformer with capacitor "C1" connected across its primary winding. While the circuit diagram shows this component as a simple transformer, it is actually a Neon Sign Transformer ("NST") and driver circuit which raises the frequency of the alternating voltage to 20,000 cycles per second or more, and the voltage to eight thousand volts or more. The output from the NST secondary passes through two chokes and two resistors to capacitor "C2" where voltage build up until the spark gap discharges. A spark creates a very sharp voltage pulse which contains all frequencies added together in a single pulse and that pulse is fed through the two capacitors "C3" and "C4" to the transmission aerials which are built so as to transmit a range of different frequencies through resonating elements of the aerial:



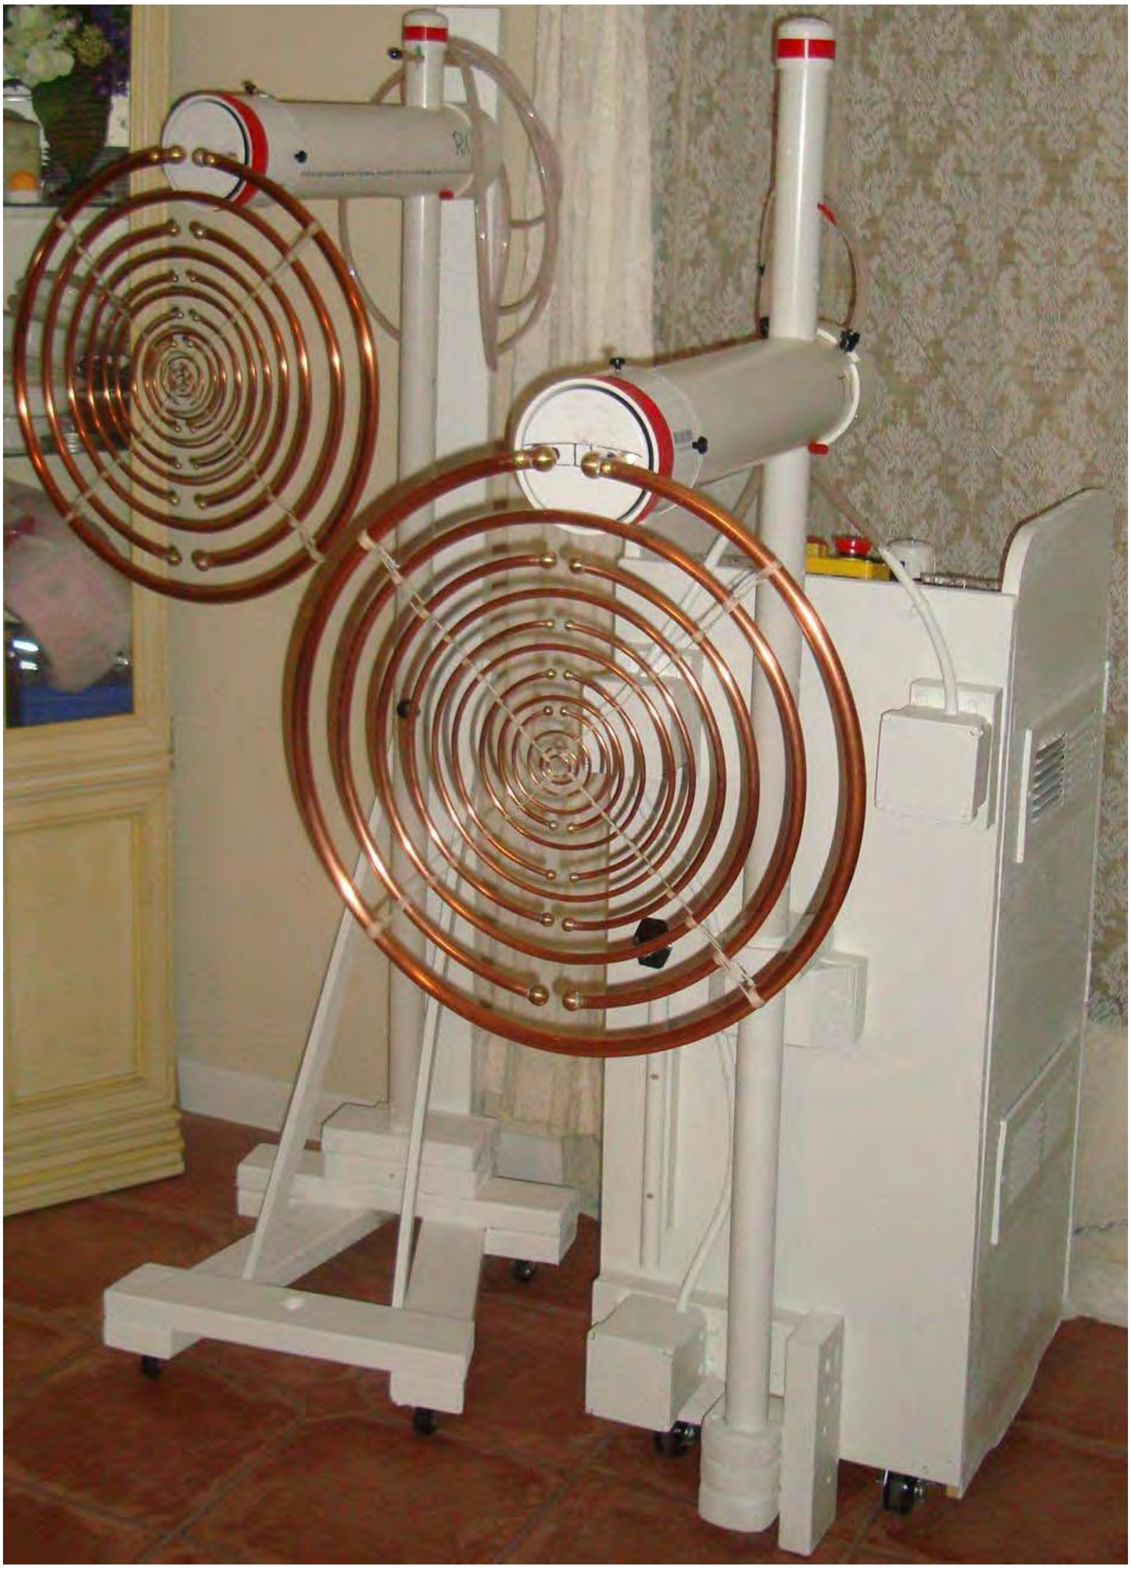
You will notice that there are many different diameters of copper pipe used in this aerial and that, combined with the diameter of the circle into which each pipe is bent, causes each section of pipe to resonate with a different frequency, and that is the operational heart of the design, but more of this later on.

So, in broad outline, we have a circuit which causes two matching aerials to oscillate (90 degrees out of phase) at a range of frequencies, and that creates a very beneficial environment for a human being, and probably any other living biological primate. The builder says: No doctor has ever healed anybody in the history of mankind. Your own body has the power to heal itself 24 hours, 7 days a week and doctors can only help the body to recover faster. I have built a machine that keeps me energised, making me feel better every time I use it, it releases me from every day stress, and heals me if that is necessary.

A logical place to start construction is to make the housing. As the builder is American, he shows dimensions in Imperial units (feet and inches) but as most people in the world work in Metric units (metres and millimetres) drawings showing measurements in Imperial units are repeated in metric units. None of the drawings are to scale.

The housing is built in three-quarter-inch solid timber or plywood which is three quarters of an inch (about 18 mm or 20 mm) thick. It has a front, a hinged back, two sides, a top, a bottom, a full size shelf and a narrow shelf. The sides have ventilators to allow the fans to blow cooling air through the housing as most of the electrical and electronic equipment is positioned inside the housing and the spark discharges cause heating.

Much of the contents of the housing is heavy and as the housing itself is substantial, the overall weight makes it advisable to mount the housing on wheels or castors so that it can be moved around easily. One aerial is attached to the housing and the other aerial is on a separate free-standing unit as shown here:



You will notice that the plastic ventilator covers span across most of the side panels. They are positioned with one above the internal shelf and one below it on each side of the housing:

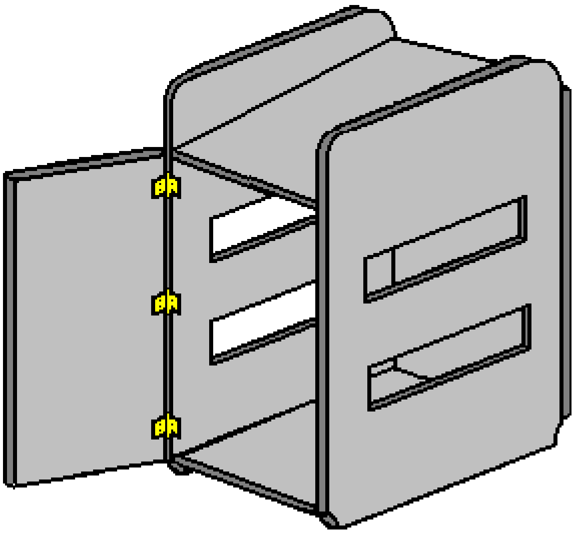
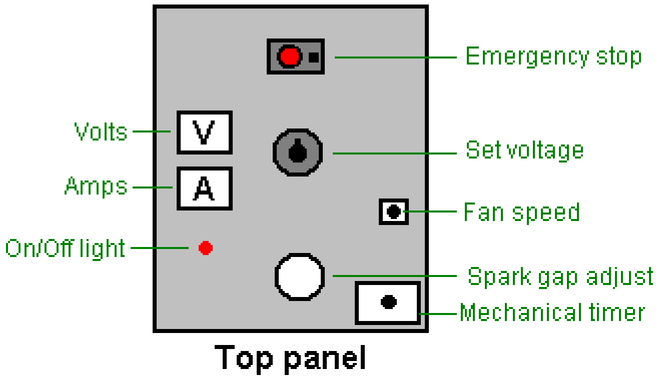
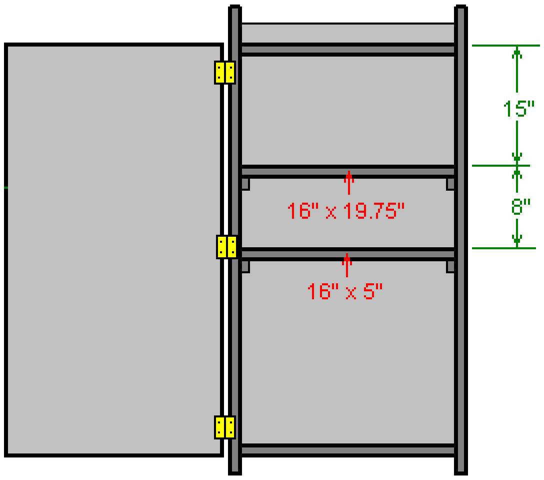
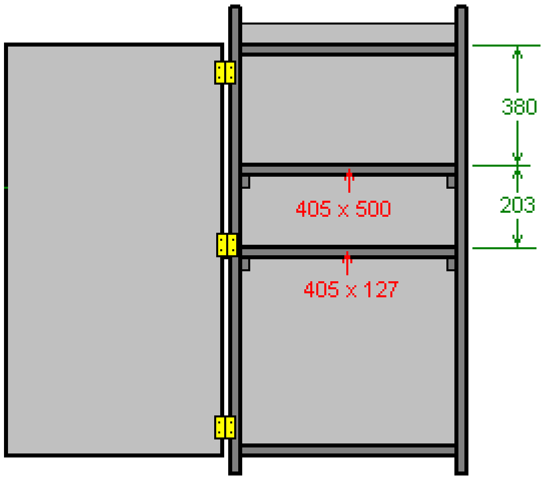
These panels can now be assembled to form the housing:





If you intend to paint the housing, then do it now before installing anything. The housing is completed by installing one full-size shelf and one quarter-width shelf inside the housing:





We are now ready to install the parts which make up the circuit. We can buy most of these ready to install, but others we need to construct as there is no commercial supplier which we can use.

We are now about to start construction of the electronic part of this circuit and so it is very important indeed that you understand the factors involved. This unit is mains powered, whether by 110-volts or by 220-volts. **These mains voltages are running at low frequency of 50 or 60 cycles per second which is a destructive frequency for humans. That voltage and speed (combined with the ability to supply substantial current at that speed) is liable to kill you if you touch it. Also, everything connected to that sort of power supply is equally dangerous.** So, you definitely disconnect the system from the mains before making any alterations to any of that circuitry. That means, every part of the circuit up to and including the primary winding of the “step-up” transformer, which is actually not just a transformer but instead is a Neon Sign Transformer circuit which raises the frequency to 20,000 cycles per second or higher, and the voltage to thousands of volts, at which point it is no longer dangerous to humans. So the dangerous part of the circuit is:

DANGEROUS SECTION

However, to put the level of danger in perspective, that level of danger applies to all mains equipment, changing a light bulb, tightening a loose wire in a mains plug, and so on. Just be very sure that the mains connection is **not** plugged in when you are connecting or altering any wiring in this part of the circuit. This is just common sense. You can wear rubber gloves as an additional safety measure if you wish.

The starting part of the circuit can be assembled quite easily. The two plastic junction boxes are mounted on the outside of the front of the machine, that is, the surface facing the 'transmitting' aerial which will be attached to this housing unit. The box on the same side as the earthing box is for housing the incoming mains.

The ‘Variac’ variable mains transformer is the next item to be connected. Please remember that this has a mains power connection to its input side and in some of its adjustment positions it will also have mains power at its output side. The Variac may look like this:

VARIABLE AC
TRANSFORMER # 116CU
AC OUTPUT VARIAC 0-140VAC
60HZ. @ 10AMPS 1.4KVA
(351375018893)

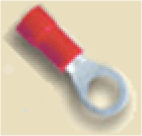
However, Variac construction varies a great deal and so your particular Variac may look different. Please remember that if your local mains supply is 220-volts that your Variac needs to be designed for that voltage. You can probably locate one on eBay.

The output from the Variac has two meters attached to it. The ammeter is inserted into one line so that the current is forced to pass through it, while the voltmeter is connected between the two output wires following the ammeter so that it shows the voltage being applied to the remainder of the circuit. It is essential that these two meters are AC types as we are not dealing with DC anywhere in this circuit. The meters for 110V use will look like this:

1PC AC 0-10A Analog
Ammeter Panel AMP Current
Meter 50*50mm No need
Shunt (181712081408)

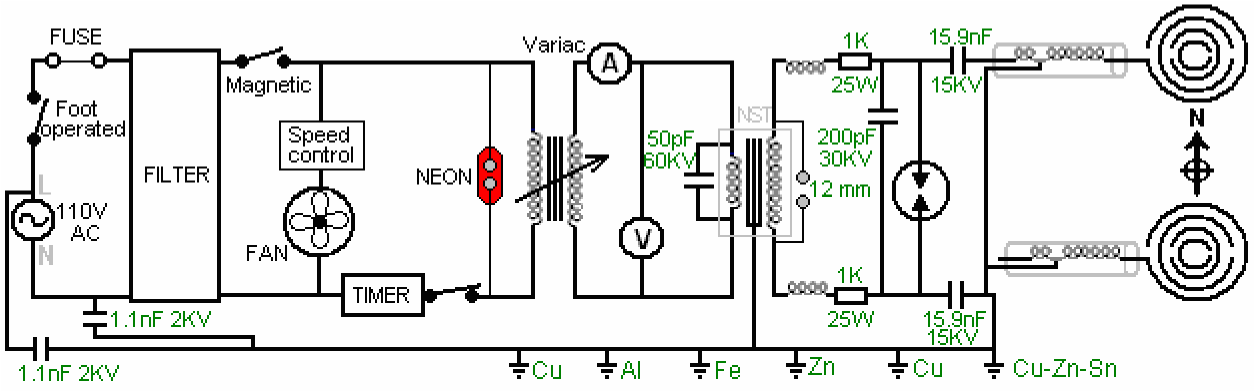
1 PC AC 0-200V Analog
85L1 Voltage Analogue Panel
meter Directly connnected
(171229243584)

Meters of this type generally have screw connections, so the connecting leads are best terminated with crimped connectors which will suit the screw connectors.

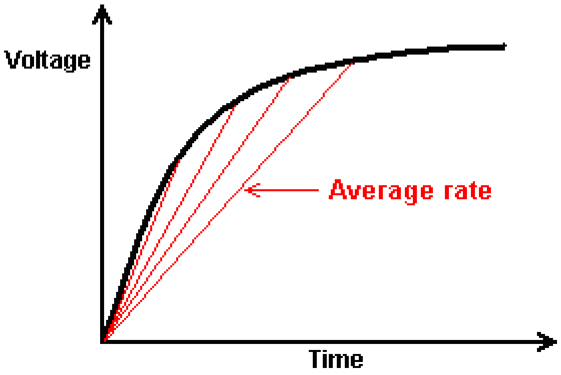


And please remember that these connections are carrying mains power and so are potentially dangerous, so be sure that the mains is not connected when you attach these metres.

We now have reached the specialist part of the circuit and we need to start paying attention to the fine details involved. Here is the full circuit:

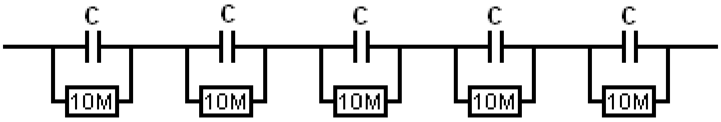


However, please understand that we are dealing with high-voltage components and they are generally hard to find. Consequently, we generally make up the required values by connecting together two or more components in a chain (known as “in series”) in order to raise the working voltage of the combination. But, doing that alters the characteristics of the group and on occasion that change can be important. For example, why connect several capacitors in series if any one of them can easily handle the voltage being used?” That is a good question as the answer is not at all obvious. The answer is because of the way that capacitors charge up. The voltage across a capacitor which is being charged, increases in a very non-linear way and it is generally illustrated like this:



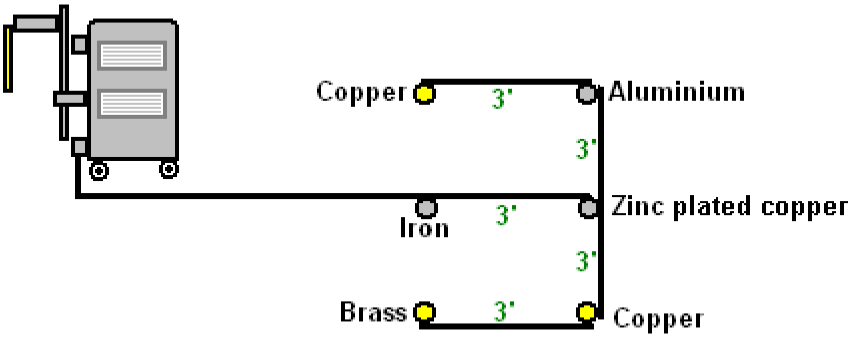
The red lines show the average rate of charge and the steeper the line, the faster the rate of charge. The greater the charging voltage relative to the size of the capacitor, the steeper the start of the line is. When connecting two or more high-voltage capacitors in series, the combined set of capacitors charges up very fast indeed. The intensity of that current is determined by the size of the capacitors in the chain, the larger the capacitors the more intense the pulse.

In theory, as capacitors are mass-produced, there is liable to be a difference in the exact parameters of any one capacitor. So, if you connect several supposedly identical capacitors in series, if one has a smaller capacity than the others, then it could charge up faster than the others and exceed its maximum voltage rating before the other capacitors have charged up to the intended level. It is not worth bothering about with just two capacitors in the chain, but when there are several, then it is worth while protecting them by connecting a very high value resistor across each capacitor:



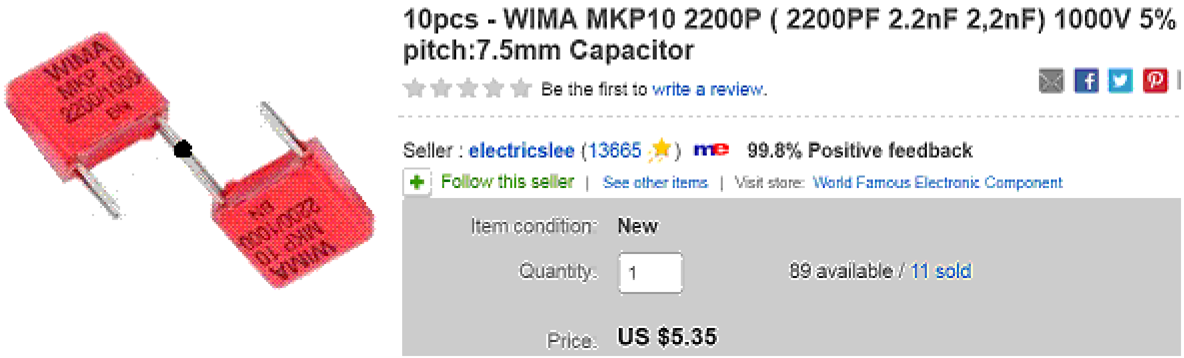
This has the effect of overcoming any such manufacturing variations and keeps the voltage across each capacitor substantially the same, without causing any major problems.

The Lakhovsky apparatus needs to have an exceptionally fine earth of its own, one which is wholly isolated from the earth wire used with the mains supply. For this, six six-foot-long (2m) earthing rods of half-inch (12 mm) diameter are driven into the ground like this:



The wires between each of the earthing rods is kept short, typically three feet or one metre, and the connection from this ground array to the earthing box on the lower outside corner of the Lakhovsky device is also kept as short as possible. Normally, this ground wire is not connected to the earthing wire of the mains supply. The six-rod earthing array shown here forms an important part of the Lakhovsky design. However, some places on Earth have soil of very poor conductivity and if you live in such an area, it may be necessary to join the mains earthing lead to your Lakhovsky earth array.

There are two pairs of capacitors in the earthing box which have not yet been shown. These are for additional cleaning up of the mains supply, intended to capture and suppress any voltage spikes arriving along the mains wiring. These are 2.2nF 1000-volt capacitors connected in pair to produce a 1.1nF 2000V composite capacitor:



10pcs - WIMA MKP10 2200P (2200PF 2.2nF 2,2nF) 1000V 5% pitch:7.5mm Capacitor

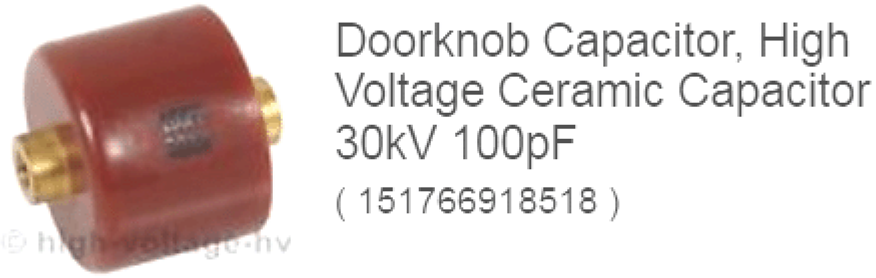
To 6-rod earthing array
Fan
Speed control
Timer

We also need to combine capacitors to make the 50pF 60KV capacitor which is connected across the input winding of the Neon Sign Transformer driver circuit. For this, we use two of these capacitors connected in series:

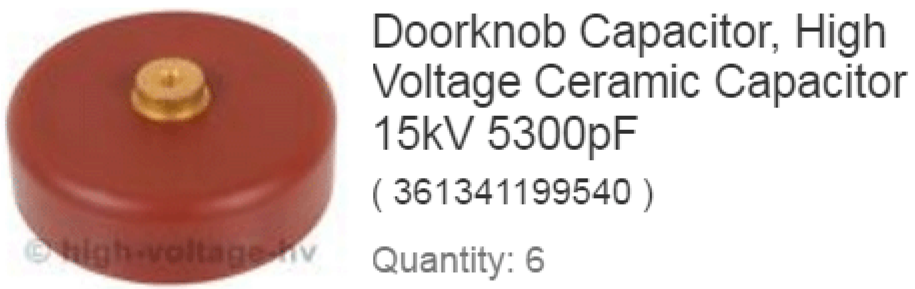


Doorknob Capacitor, High Voltage Ceramic Capacitor 30kV 100pF

(151766918518)

© high-voltage-hv

And finally, we need two identical capacitors with a value of 15.9 nF and a 45KV rating, and we will use three of these capacitors connected in series, to make up each of these two capacitors:



Doorknob Capacitor, High Voltage Ceramic Capacitor 15kV 5300pF

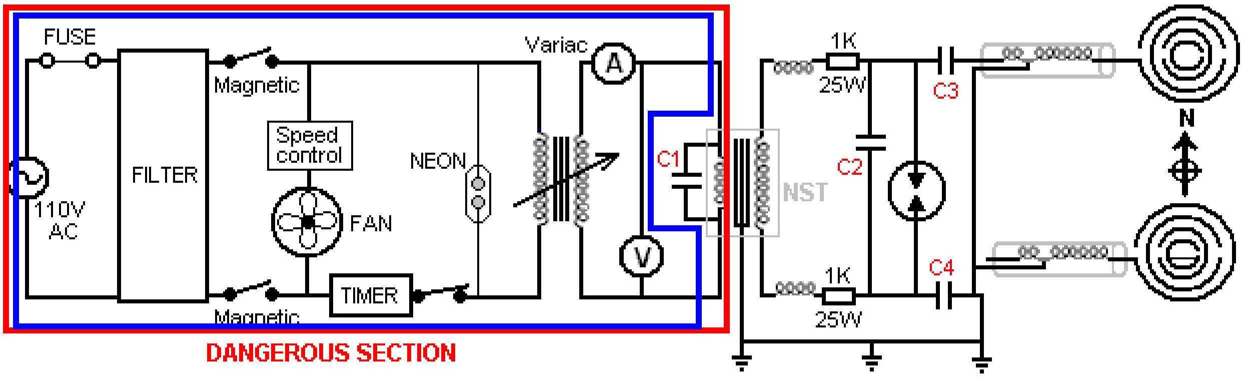
(361341199540)

Quantity: 6

The NST unit is readily available as these units are used to drive neon signs, but a common practice nowadays is for the manufacturer to build in circuitry to stop the circuit operating if there is “leakage to earth”. While that is a sensible precaution, it must be avoided in this circuit as the spark gap discharges continuously to earth and so an earth-leakage protected NST will stop the circuit operating. There are three ways around this. First is to find an old NST (or build one yourself) which does not have the protection circuit. Second is to open a new NST and disable the protection circuit (if your knowledge of circuitry is up to that), or third, ask the manufacturer to supply you one which has the circuit disabled by the manufacturer. Ideally, you want an NST which provides 10,000 volts at 60 milliamps at a frequency of 20,000 cycles per second (or faster).

You need to decide where the equipment will be used during the treatment session. This location needs to have the transmission aerial array in the direction of North and the receiving aerial in the direction of South. Also, the equipment needs to be at least one metre away from equipment such as computers, TVs and anything else of that nature, and away from permanently mounted equipment such as wall-mounted heaters or air conditioning units. Remember that walls do not block electronic signals (if they did, then radios would not work indoors). Having chosen the position, prepare a mains plug and length of cable from the nearest mains socket to your device. Also, the chosen working position needs to be close to where the 6-rod earthing grid is physically located.

Please remember that having passed through the fuse and the filter, the cable exiting from the plastic box is still carrying dangerous mains power. The drawing shows the “Live” mains wire as brown which is the European standard (it used to be red but was changed as 30% of males are colour blind). In America that wire is colour-coded black and the European blue ”neutral” wire is colour-coded white in America. The wire coming from the filter unit connects next to the emergency Off switch box and care needs to be taken as the cable leaves that box. First it connects to the fan speed control and the fan. Then it connects to the mechanical 15-minute timer and when it exits from the timer module, the neon is wired across it to show when the power is on to the rest of the circuit, and the wires then continue to the input of the Variac variable transformer:

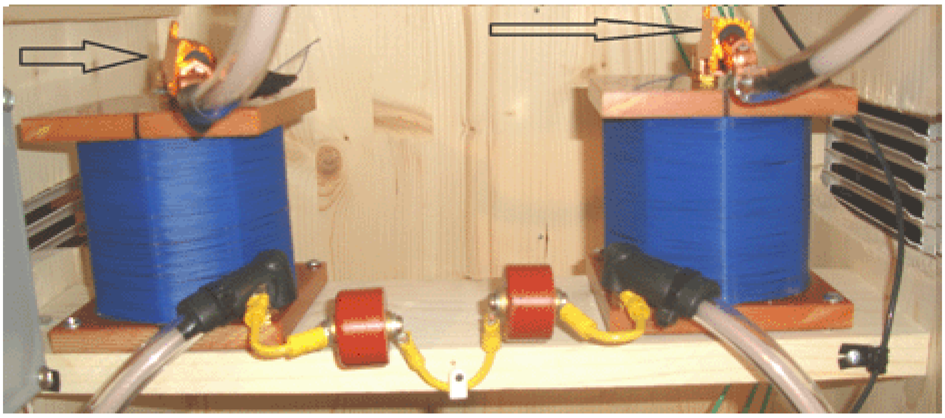


Remember that we are still solidly inside the mains power danger zone as we have just completed the wiring inside the blue rectangle. The wiring connections made can be soldered connections which are then insulated, or they can be mains-voltage screw connectors or crimped connectors. No matter which method is used, the finished result should make it impossible to touch any live wire or connector with a finger, so insulate everything as people make mistakes and are liable to forget that they have left the equipment plugged in to the mains.

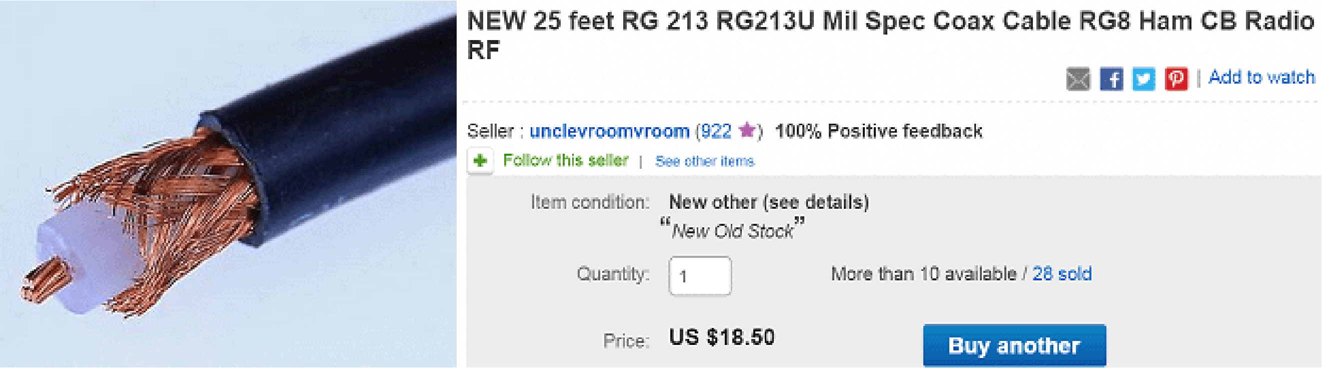
The output of the Variac is still mains power and it is wired across the AC voltmeter mounted on the control panel and to one side of the AC ammeter which is also mounted on the control panel. Please remember that the wires coming away from these two meters are carrying mains power and all joints still need to be insulated. The final connection in this section is to the input of the Neon Sign Transformer driver circuit which also has the “C1” capacitor connected across it. From this point onwards, the frequency rises by a factor of 200 times or so and that makes it much safer for human contact.

Each wire coming out of the NST unit has a coil called a “choke” attached to it. You wind these coils using #24 AWG enamelled solid copper wire which has a diameter of 0.511 millimetres, and some thick nylon fishing line. Each coil is wound on a 3.5 inch (90 mm) spool. The spools can be made up using several layers of paper, or they can be plastic. However, if they are plastic then be warned that only “white schedule 40 PVC” material is suitable for this kind of work as other colours have additives which make the material unsuitable. Each of these chokes are wound with 100 turns of wire and each wire turn is separated from its neighbour by running a thick strand of fishing nylon line alongside the winding wire. That is, the coil is wound with the enamelled copper wire and the nylon line beside it, producing a coil of wire, nylon, wire, nylon, wire, etc. for a hundred turns of each. Each finished coil should have an inductance of 426 micro-Henries. These chokes are installed on the small lower shelf and each has a 1K 25-watt resistor attached to its output wire:

Resistor
1K 25W



It needs to be understood that ordinary wire is just not suitable in a circuit like this where high voltages are being carried by the wire. The insulation of ordinary wire will just break down and it could cause a short-circuit and possibly a fire. Because of this, you need to use wire with extra high quality insulation. The builder has chosen to modify coaxial cable and enclose it in an additional layer of plastic pipe. The first step is to buy high-quality coaxial cable:



NEW 25 feet RG 213 RG213U Mil Spec Coax Cable RG8 Ham CB Radio RF

Seller : unclevroomvroom (922 ★) 100% Positive feedback

Item condition: New other (see details) “New Old Stock”

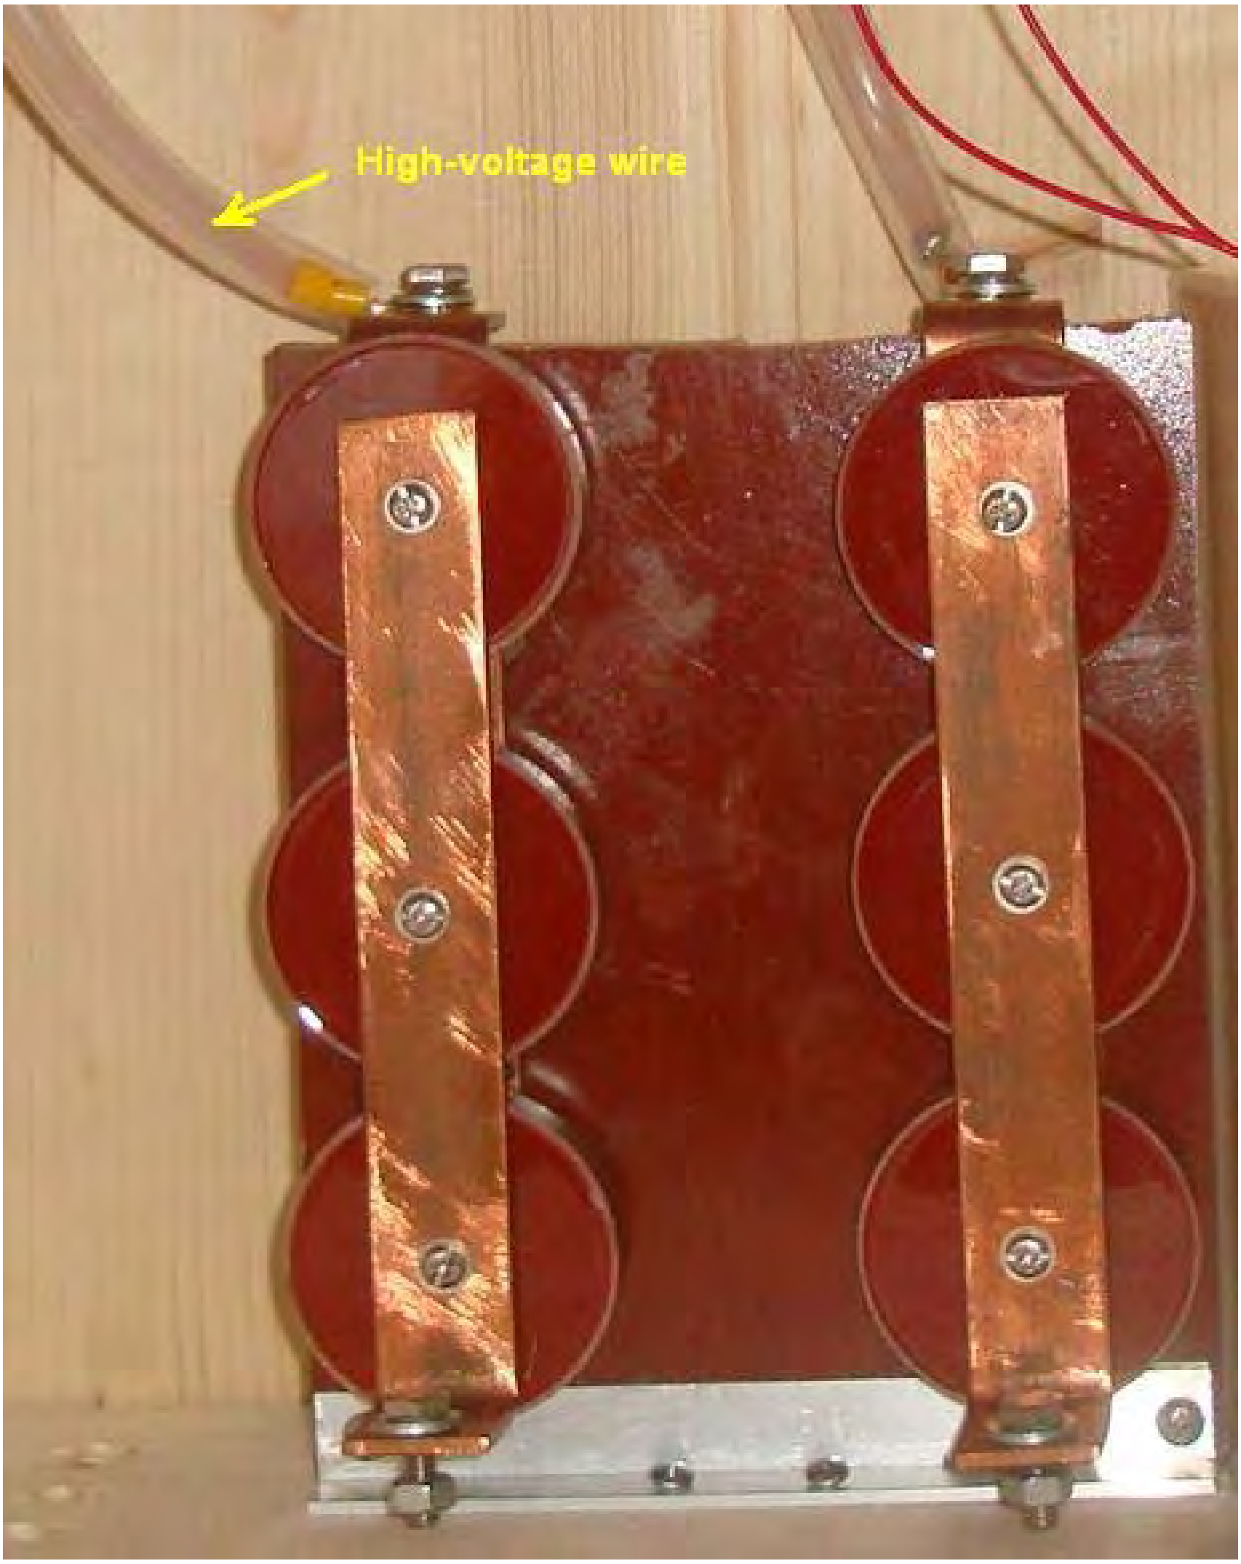
Quantity: 1

More than 10 available / 28 sold

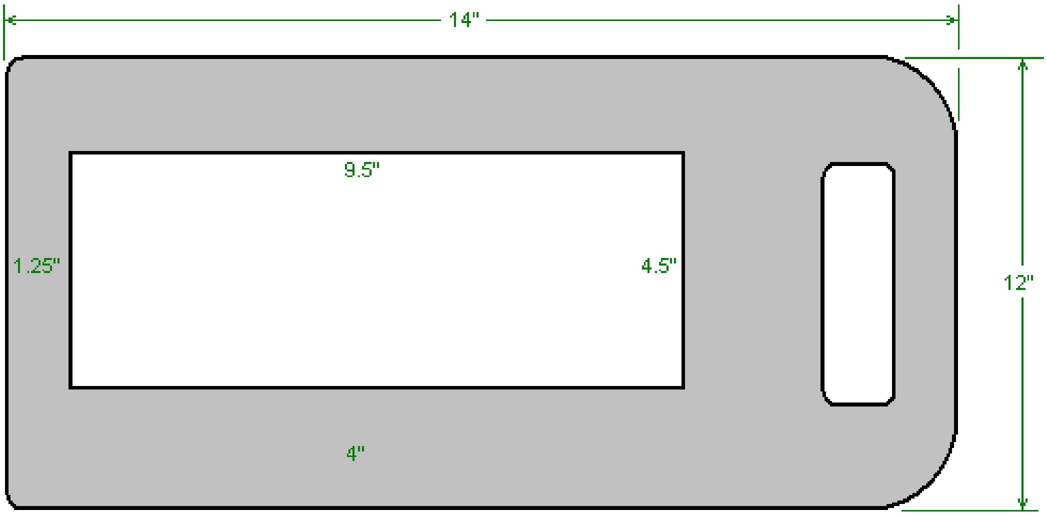
Price: US $18.50

The cable is then modified by removing the dark outer insulation and the laced copper screen which leaves the central copper conductor surrounded by a thick plastic layer.

This arrangement can be seen clearly here where two sets of three capacitors are strapped together to form the two 5.9nF 45KV capacitors, which being high-voltage, have the high-voltage wire connecting them to the Neon Sign Transformer circuit:

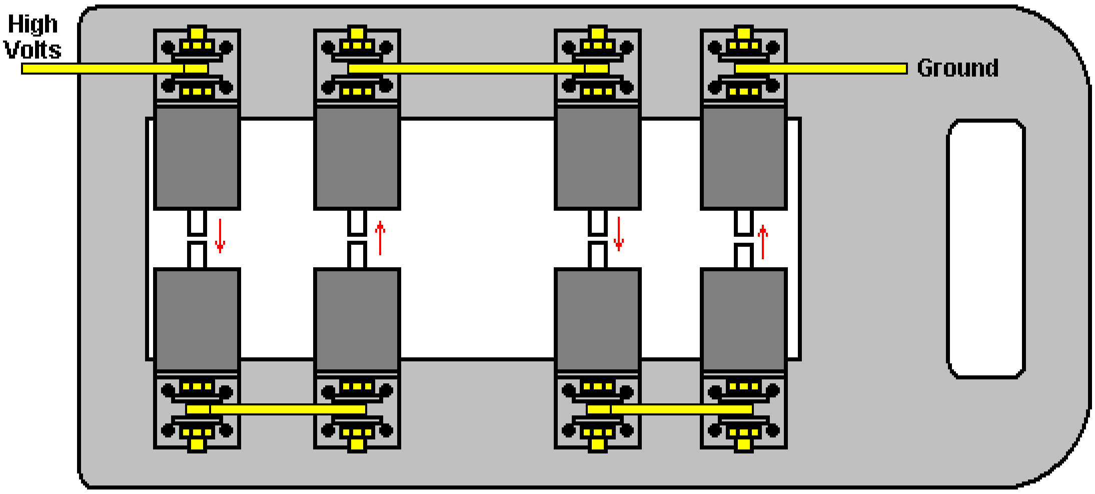


We now come to the items which we need to fabricate for this Lakhovsky system. We will start with the spark gap. This is built on a plastic chopping board. These boards are made from very rigid UHMWP (Ultra High Molecular Weight Polythene) plastic material and they are available in white and various colours. They are tough but can be sawn and are an excellent non-conductive constructional material. The chopping boards used by the constructor were 14 x 10 x 3/8 inches (355 x 254 x 9 mm) in size. The baseboard has a rectangular piece removed from it:



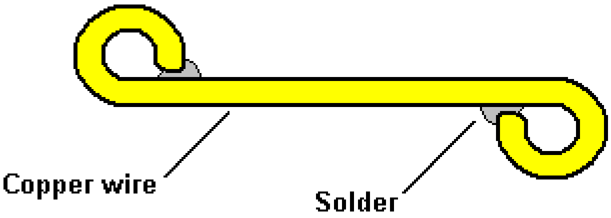
The rectangle will have four spark gaps mounted on one side and two computer cooling fans mounted on the other side, and the board will then be mounted on its edge on the full-size upper shelf.

While there are four spark gaps mounted on the board, they act as a single gap because they are interconnected using 5 mm diameter solid copper wire. This splitting of the spark gap into multiple gaps is said to reduce the noise of the sparks. The arrangement is like this:



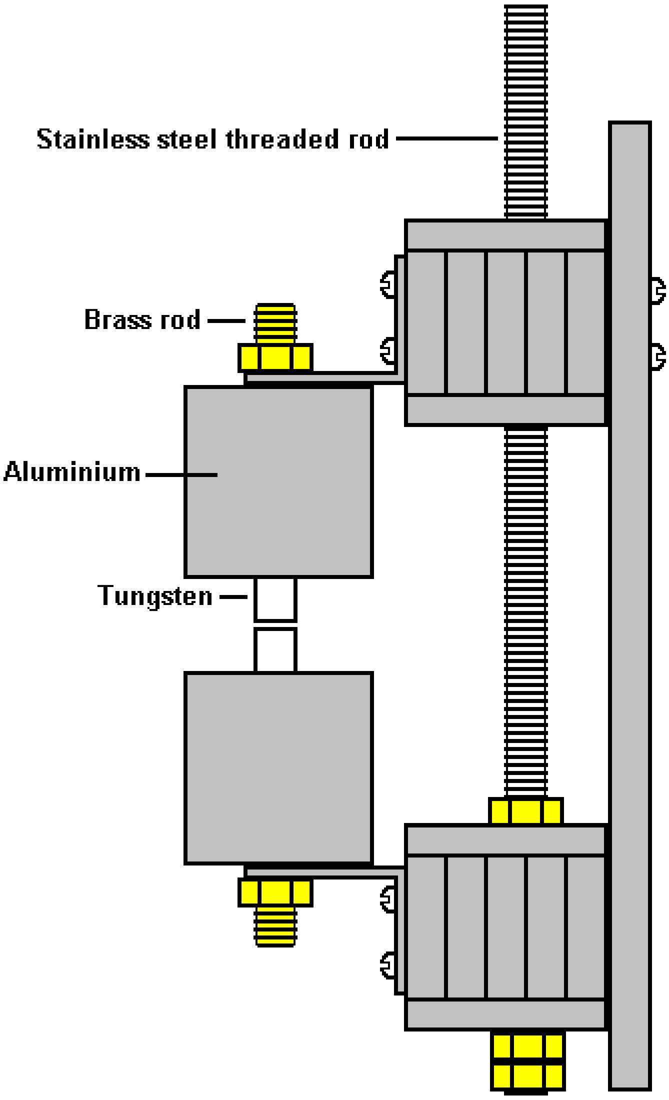
Each section of the spark gap is made from a short length of tungsten rod which can stand the high temperature generated by the sparks. The tungsten rod is inserted into a section of 1.5 inch diameter aluminium rod, which is tapped at the other end to allow a length of brass rod to be screwed into it. An aluminium mounting bracket is bolted to the brass rod using a brass nut and then a length of 5 mm diameter solid copper wire is flanked by two washers and clamped tightly with a third brass nut.

Secure electrical connections can be made like this:

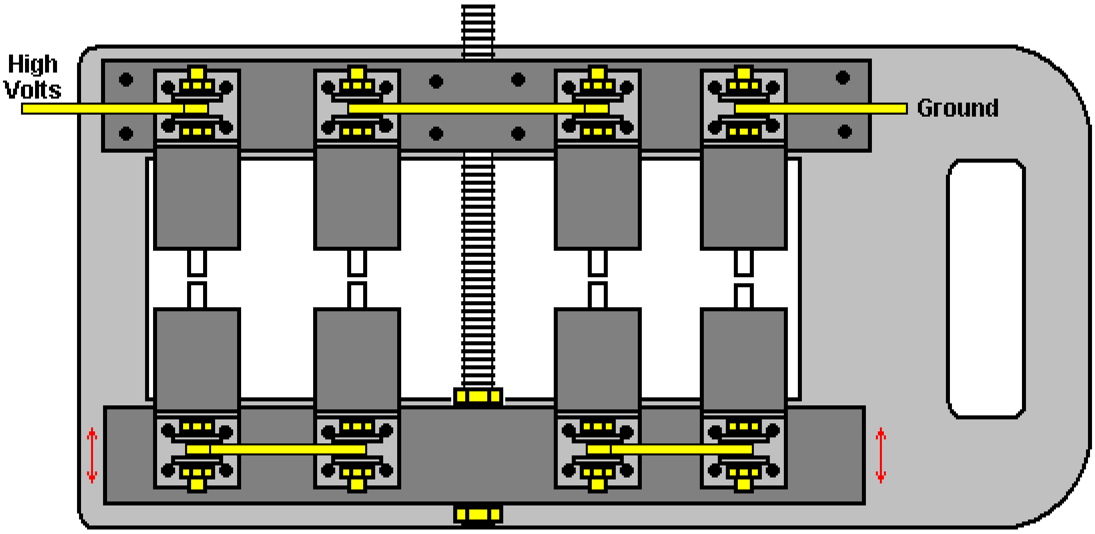


For this, the wire is bent around in a circle in the direction that a tightening nut turns, and if possible, the end is secured with a solder joint. If this is done, then even without the solder and without the washer, tightening a nut in direct contact with the wire tends to pull the wire tighter against the brass rod instead of distorting the loop and spoiling the electrical contact.

However, the overall arrangement shown does not allow the width of the spark gap to be adjusted. The adjustment is normally very small, varying from a 0.01 mm gap to a 0.04 mm gap, but for very ill patients, a gap of up to 5 mm may be used. That five millimetre movement is small being only 3/16" or so, but this adjustment is very important as part of the treatment. To arrange for this movement, the lower four components are mounted on a movable block of plastic and a length of 3/8 inch (10 mm) diameter threaded stainless steel rod is used to make the spark gap adjustable. This adjustable arrangement is produced by locking the upper row or four electrodes in place and placing the lower four electrodes on a wide strip of plastic board material which is attached to a 3/8" (9 mm) diameter stainless steel threaded rod, allowing the tiny movement required. The stainless steel rod is extended by attaching a "bakelite" insulating plastic rod to it, running the bakelite rod through the top of the housing and attaching an insulating plastic knob to it. This arrangement is constructed like this:



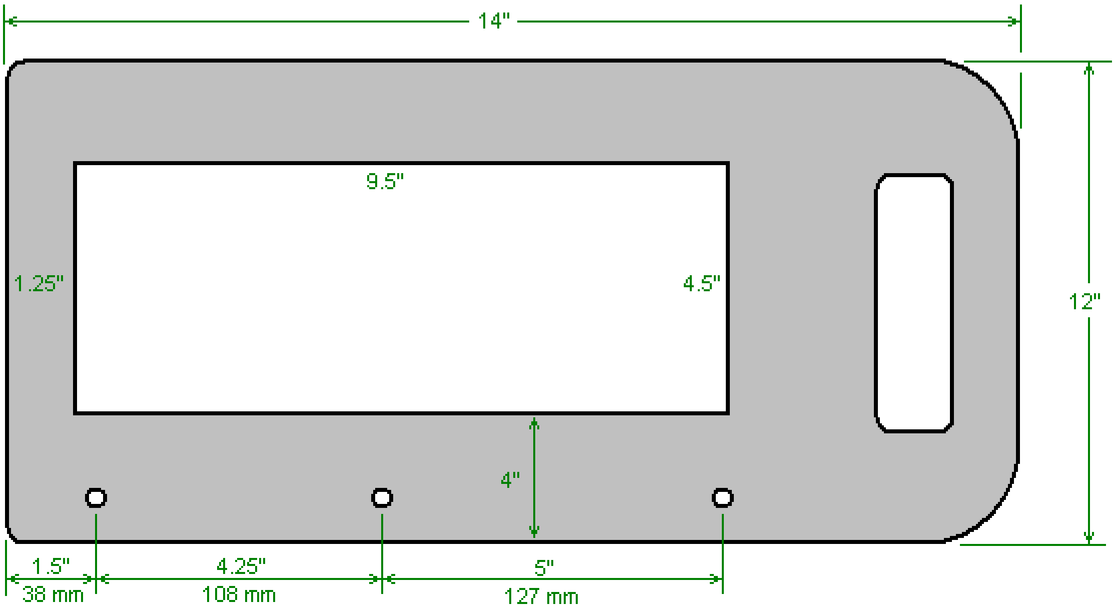
The lowest bracket is bolted to the full-size timber shelf and computer fans are attached to the main vertical plastic plate to blow cooling air across the four spark gaps. The stainless steel rod passes through the upper block of plastic strips but is not connected to them in any way.



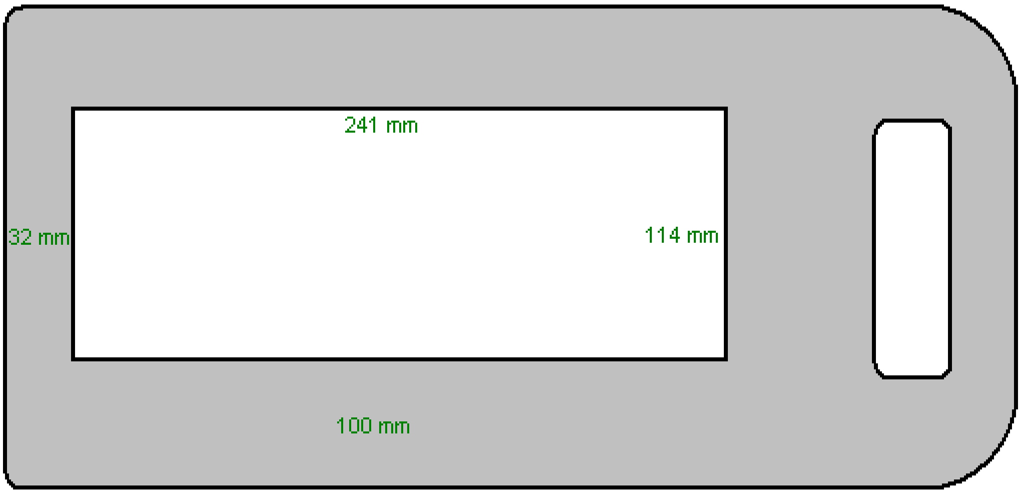
High Volts
Ground

The dimensions for constructing this adjustable spark gap are as follows.

The base board has just one central opening cut in it as shown here:



14"
9.5"
1.25"
4.5"
12"
4"
1.5"
38 mm
4.25"
108 mm
5"
127 mm



241 mm
32 mm
114 mm
100 mm

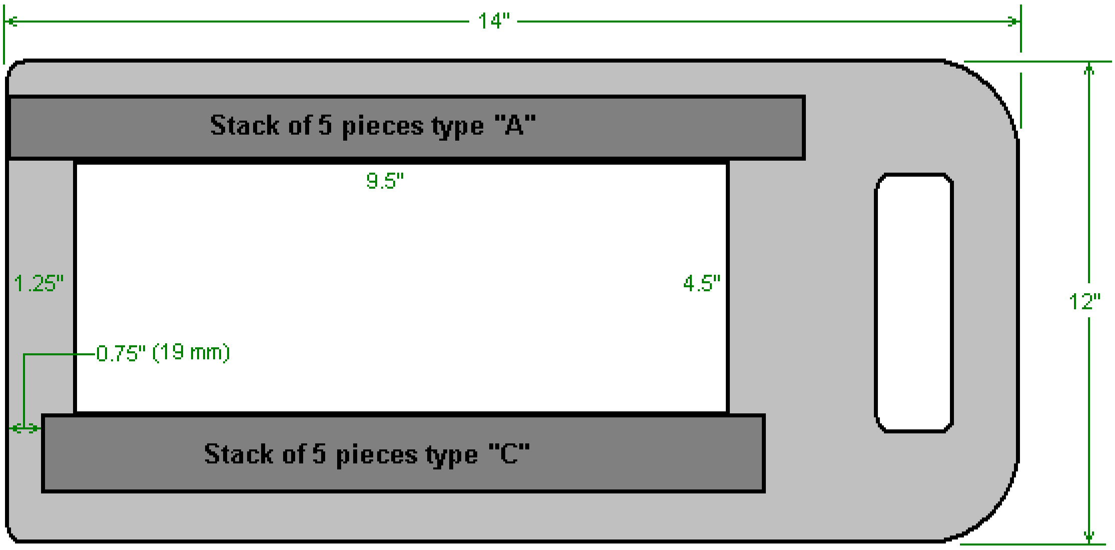
This board is called type "B" and the mounting holes drilled in it allow it to be bolted to a 12" (305 mm) length of 1.5" x 1.5" (40 mm x 40 mm) aluminium angle.

The following strips are now cut from other HDMWP plastic chopping boards:

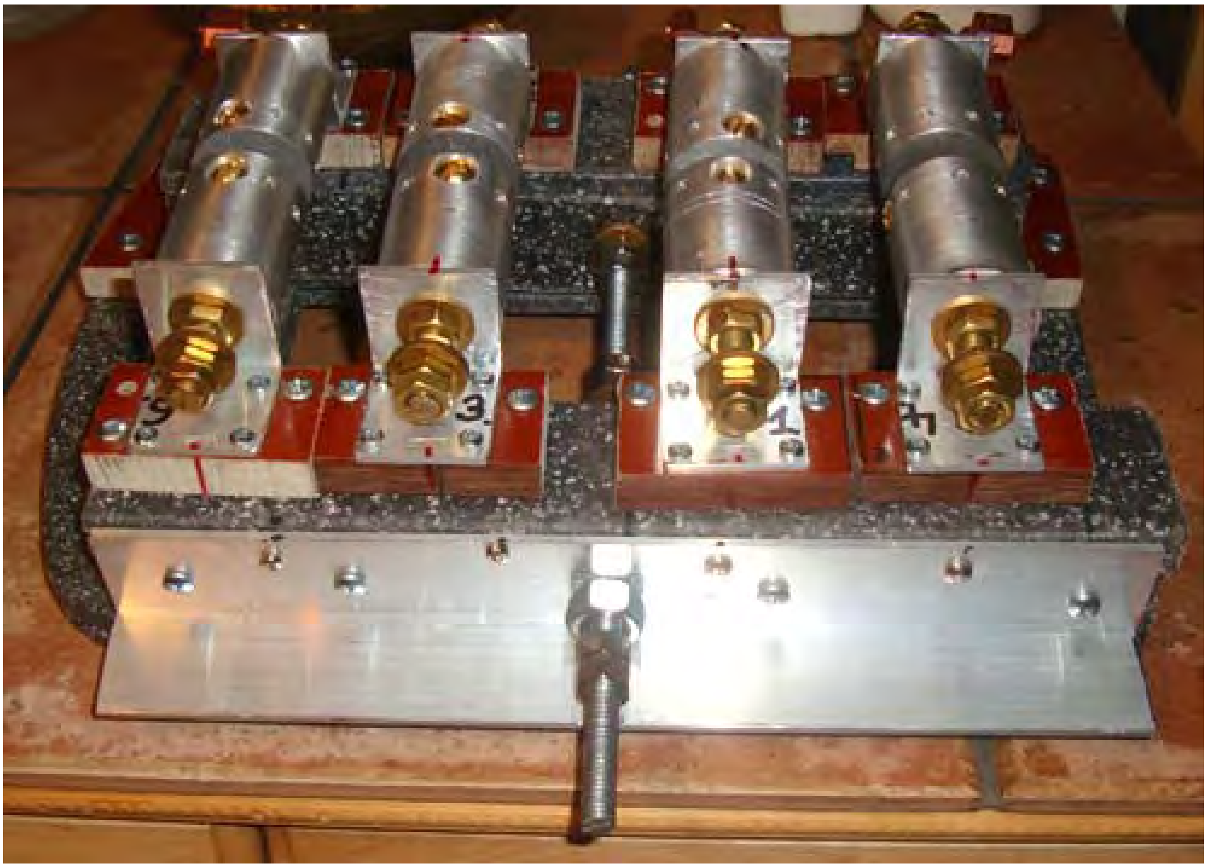
5 pieces 12" x 2" (305 mm x 50 mm) called type "A".
5 pieces 11.5" x 2.25" (292 mm x 57 mm) called type "C".
2 pieces 11.25" x 1.75" (286 mm x 45 mm) called type "D".

These pieces fit together to form the stationary support block and the movable support block on which the spark gap components are mounted.

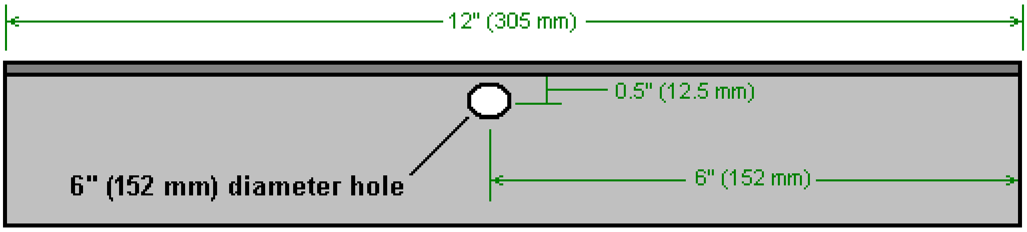
They are positioned like this:



14"
Stack of 5 pieces type "A"
9.5"
1.25"
4.5"
12"
0.75" (19 mm)
Stack of 5 pieces type "C"

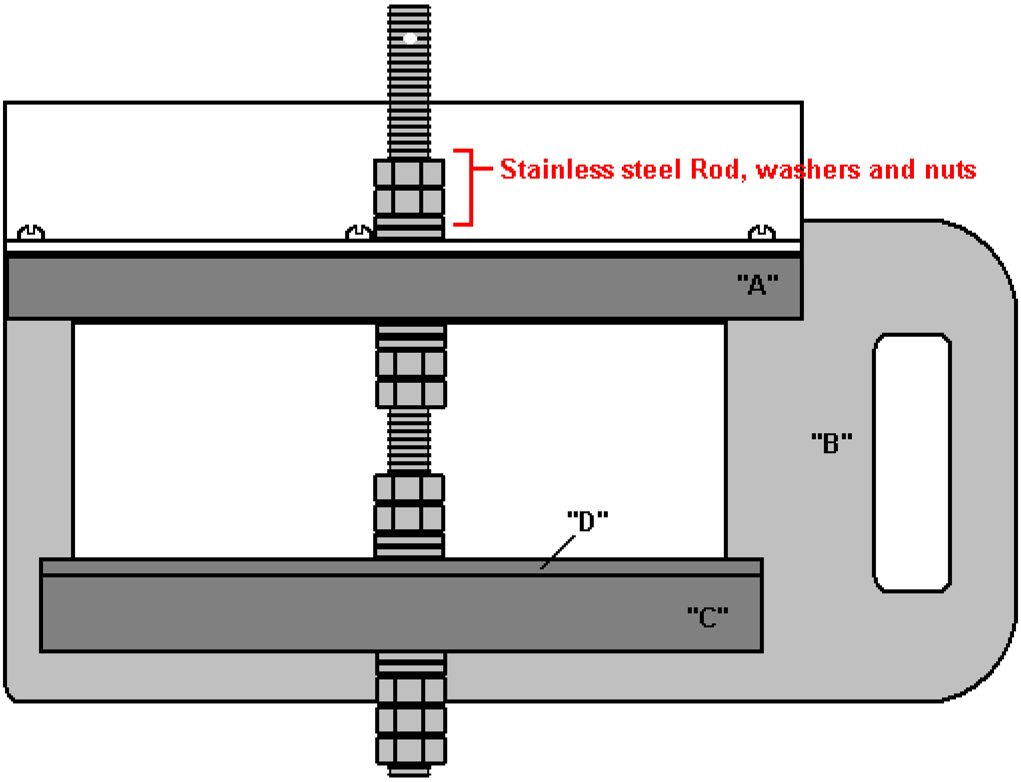


The piece of aluminium angle has the adjustment rod fed through it, so it needs to be drilled like this:

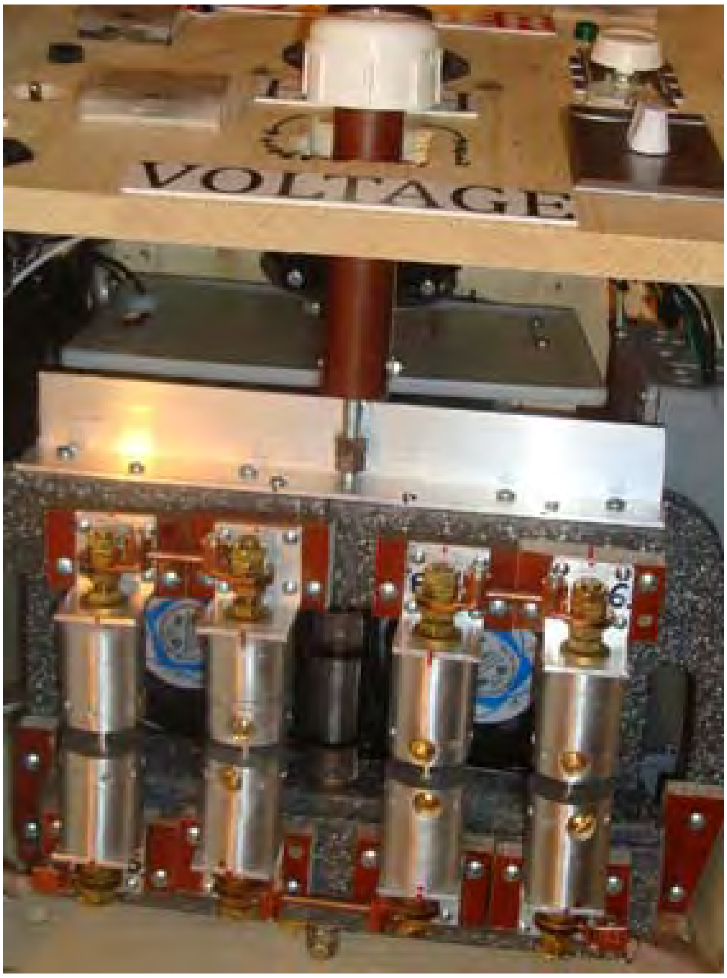


12" (305 mm)
0.5" (12.5 mm)
6" (152 mm) diameter hole
6" (152 mm)

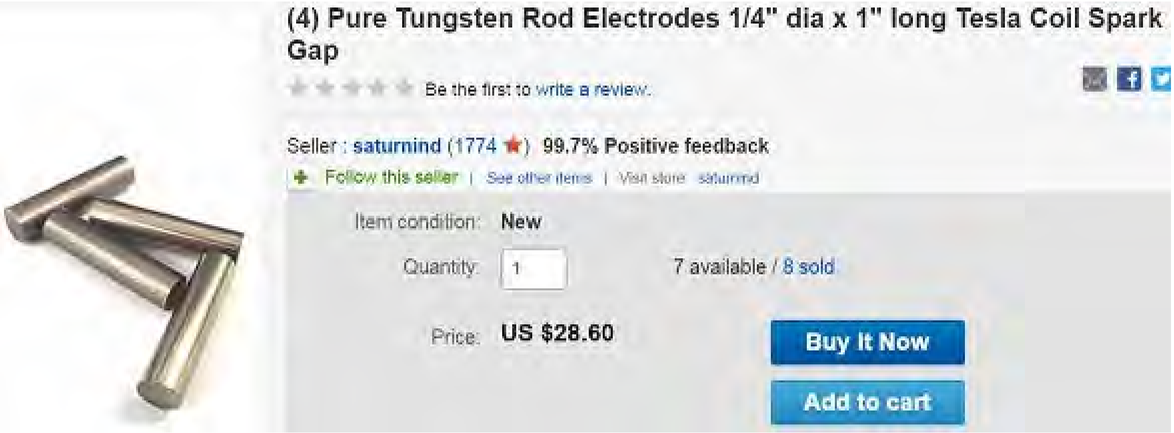
A hole of about 1/8" (3 mm) is drilled through the stainless steel threaded rod, about 0.5" (12 mm) from the end ready for attaching the insulating bakelite rod and plastic knob. The aluminium angle is then bolted to the stack of "A" plastic pieces and fitted with the washers and nuts shown here:



Stainless steel Rod, washers and nuts
"A"
"B"
"D"
"C"



One detail to be mentioned is the tip of each spark gap. As that part gets hot, using tungsten is sensible and so the builder bought in eight pieces each one inch (25 mm) long and a quarter inch (6 mm) in diameter. These were bought on eBay:



(4) Pure Tungsten Rod Electrodes 1/4" dia x 1" long Tesla Coil Spark Gap

Be the first to write a review.

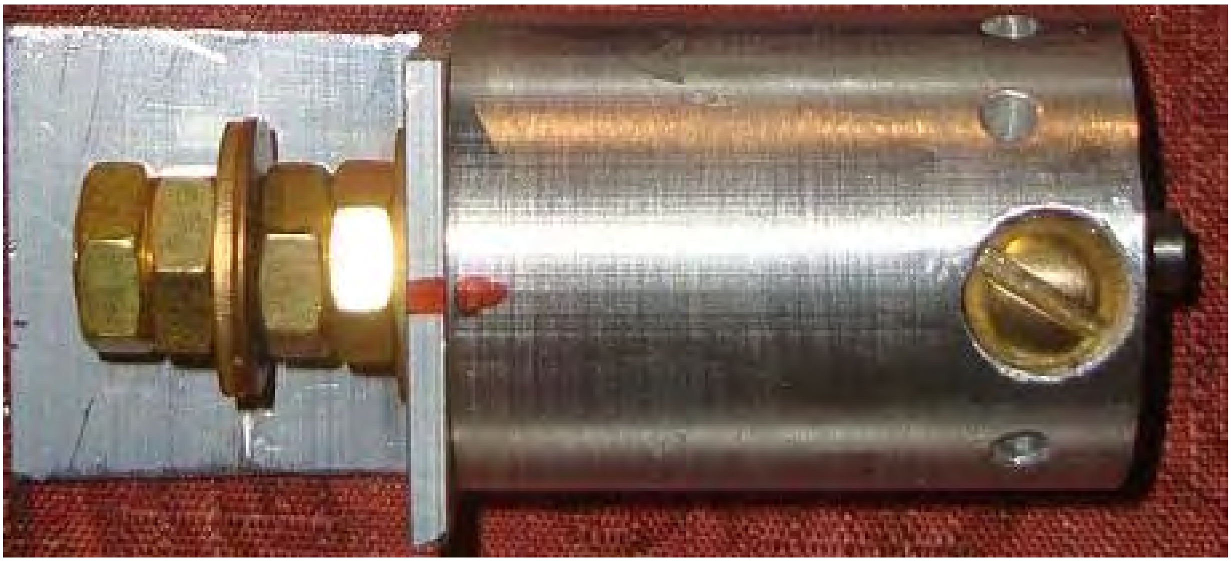
1-1/2" Diameter 6061 Aluminum Round Rod 2" Length T6511 Extruded 1.5 inch Dia

(322186173598)

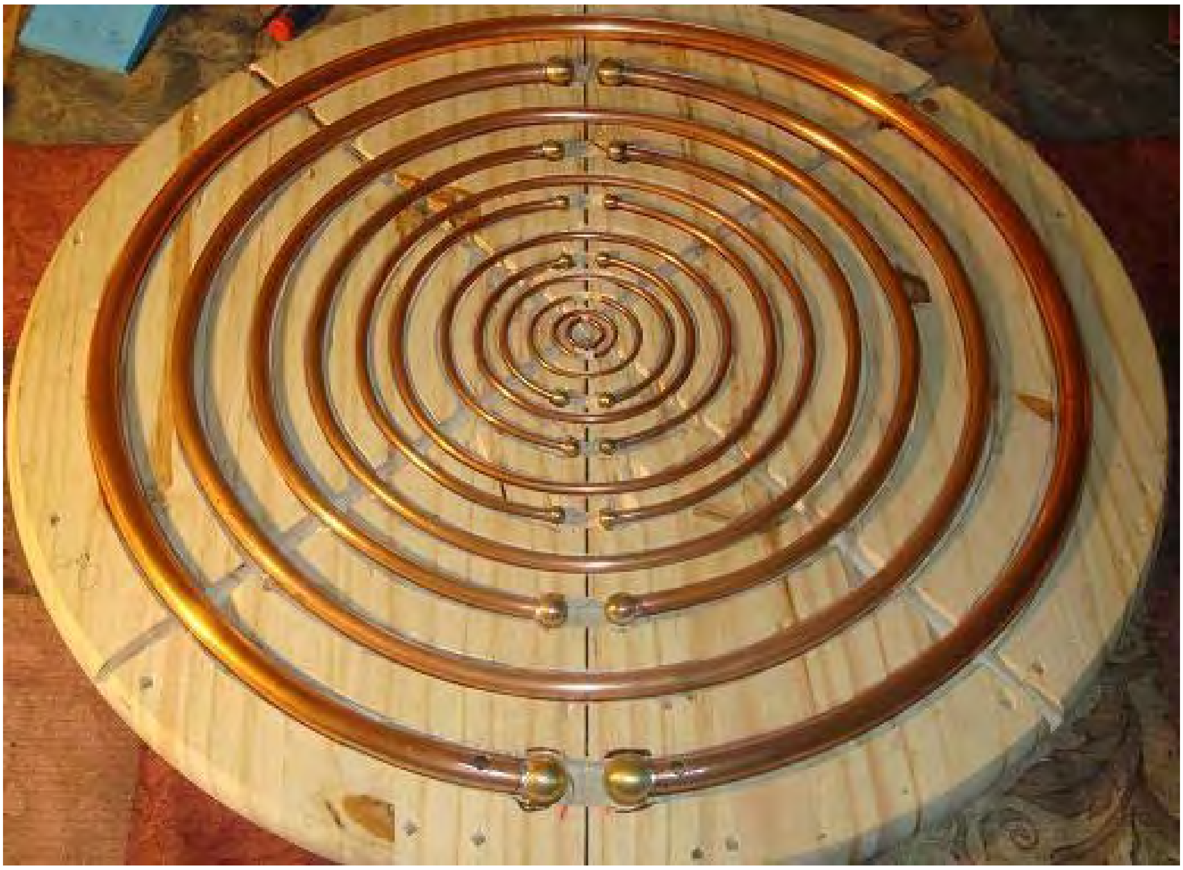
Quantity: 10

And each was inserted into an axial hole drilled in the short section of 1.5” (40 mm) diameter aluminium solid bar, and held in place with a brass locking screw at right angles, tapped into the aluminium rod:

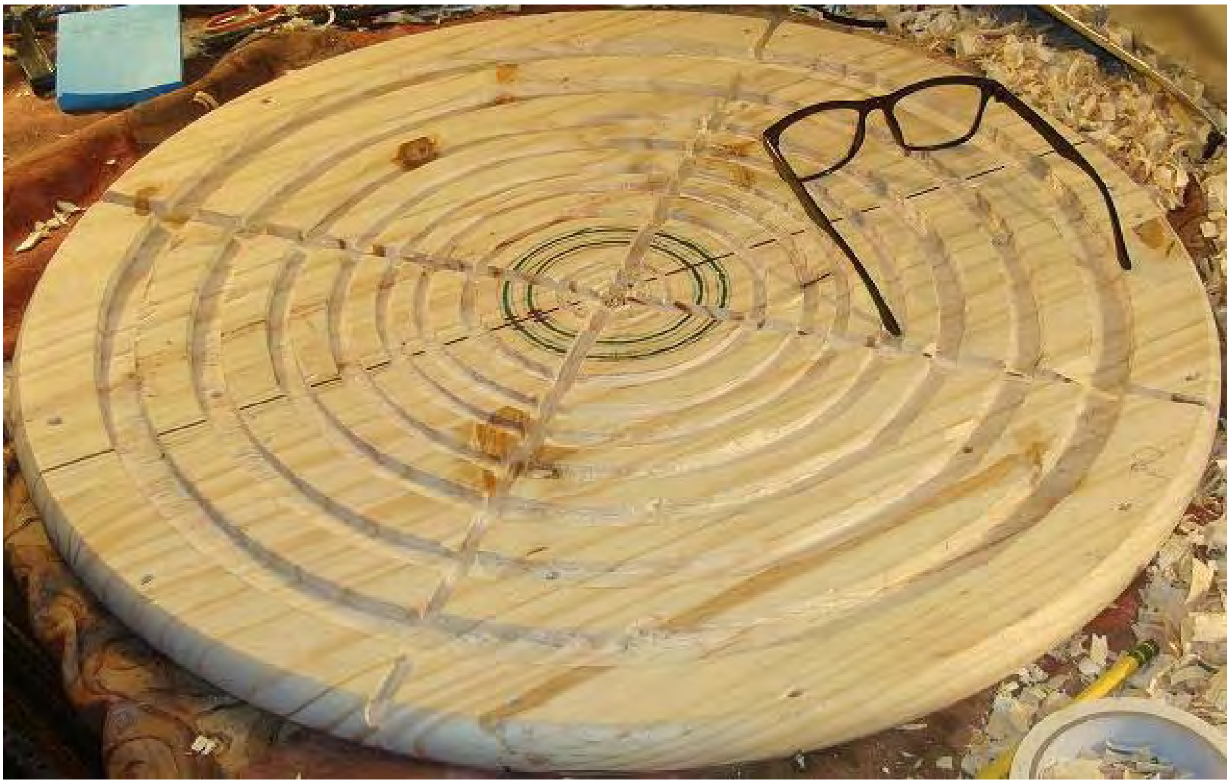


The mounting bracket is clamped to the aluminium section using a piece of 3/8-inch brass threaded rod which has been tapped into an axial hole.

The aerials:
Once the construction of the spark gap has been completed, we need to make the two aerial arrays. For this, we need to use a one-inch thick timber template so that the positioning and sizes of each ring is exactly right. While plywood could be used for the housing, it is **not** suitable for this template.



The idea is to cut a groove or channel for each pipe ring, bend and place each ring in its groove, and when all of the rings are in place, use the two extra diagonal grooves to tie the rings securely in place so that when they are hanging in the air they remain in exactly the correct positioning. The builder cut the larger grooves using a half-inch chisel, a quarter-inch chisel and a mallet and the smaller grooves using screwdrivers instead of chisels. Here is what the board looks like in an advanced stage of construction:



First, the exact ring positions are marked out on the board. These are the diameter of the centreline of each pipe, the groove width and the groove depth:

Ring 1: Diam 500 mm, width 14.5 mm, depth 8 mm, copper diameter 14 mm, buy 144"
Ring 2: Diam 400 mm, width 12.3 mm, depth 7 mm, copper diameter 12 mm, buy 120"
Ring 3: Diam 320 mm, width 10.3 mm, depth 6 mm, copper diameter 10 mm, buy 96"
Ring 4: Diam 275 mm, width 8.2 mm, depth 5 mm, copper diameter 8 mm, buy 72"
Ring 5: Diam 225 mm, width 6.2 mm, depth 4 mm, copper diameter 6 mm, buy 115"
Ring 6: Diam 184 mm, width 6.2 mm, depth 4 mm, copper diameter 6 mm.
Ring 7: Diam 143 mm, width 6.2 mm, depth 4 mm, copper diameter 6 mm.
Ring 8: Diam 112 mm, width 6.2 mm, depth 4 mm, copper diameter 6 mm.
Ring 9: Diam 81 mm, width 6.2 mm, depth 4 mm, copper diameter 6 mm.
Ring 10: Diam 51 mm, width 3.1 mm, depth 3 mm, copper diameter 3 mm. buy 36"
Ring 11: Diam 30 mm, width 3.1 mm, depth 3 mm, copper diameter 3 mm.
Ring 12: Diam 14 mm, width 3.1 mm, depth 3 mm, copper diameter 3 mm.

The soft copper pipe lengths were bought from China and the lengths shown above are sufficient for making two aerials. Brass spheres were soldered to the ends of the larger tubes. These were bough in America as they were easier to find there. The quantities needed are:
4 size 7/8", 4 size 3/4", 4 size 5/8", 4 size 1/2", and 20 size 3/8". The 3 mm diameter rings were left open ended and care was taken to ensure that the pipe was circular and not damaged in any way at the ends. This style of pipe cutter was used:

The copper pipe used in these aerials is made of “soft” copper which can be bent by hand, unlike the current UK plumbing variety which is very rigid and needs a powerful mechanical device to bend it. The greater flexibility is caused by a final annealing process during manufacture.

The builder describes the finishing steps like this: Starting with the biggest ring to the smallest one. I always cut in with a carpet knife on the two side's markings before I started chiselling out the tube size line. Also I marked a 3/8" wide 1/2" deep cross for making room to tie the rings together. After this I just kept chiselling away for three days when I had time! Now the fun part; I took the copper tubes and started forming them in to the template from the number 12 ring to the biggest ring, the number 1. As seen on the photo, the number 1 ring's cut ends in the assembled antenna, with the gap at the top! The number 1 ring will be attached to the output coil later on; it will also hold all other 11 rings in their positions.

Thinking ahead before I started making the rings I drilled the correct sphere holes on the template paying attention on the up and down positions of the spheres. It can easily confuse anybody after working for so many hours on this part of the project. I triple checked all the rings positions to make sure that they are correct before I started to tie the rings together while they were still in their grooves. But I was not ready yet! When all the rings are formed, I drilled the spheres with the correct holes and soldered them on to the copper tubes. I ordered solid brass spheres, no holes in them at all. I used a stand drill and had two aluminium pieces installed on the two sides of the table vise which was holding the spheres for drilling. I drilled about half way into any of the spheres from straight up to the centre of the sphere.

4 pieces of 7/8" spheres (for two antennas) got centre drilled half way in with 17mm drill bit
4 pieces of 3/4" spheres (for two antennas) got centre drilled half way in with 15mm drill bit
4 pieces of 5/8" spheres (for two antennas) got centre drilled half way in with 13mm drill bit
4 pieces of 1/2" spheres (for two antennas) got centre drilled half way in with 11mm drill bit
20 pieces of 3/8" spheres (for two antennas) got centre drilled half way in with 8mm drill bit

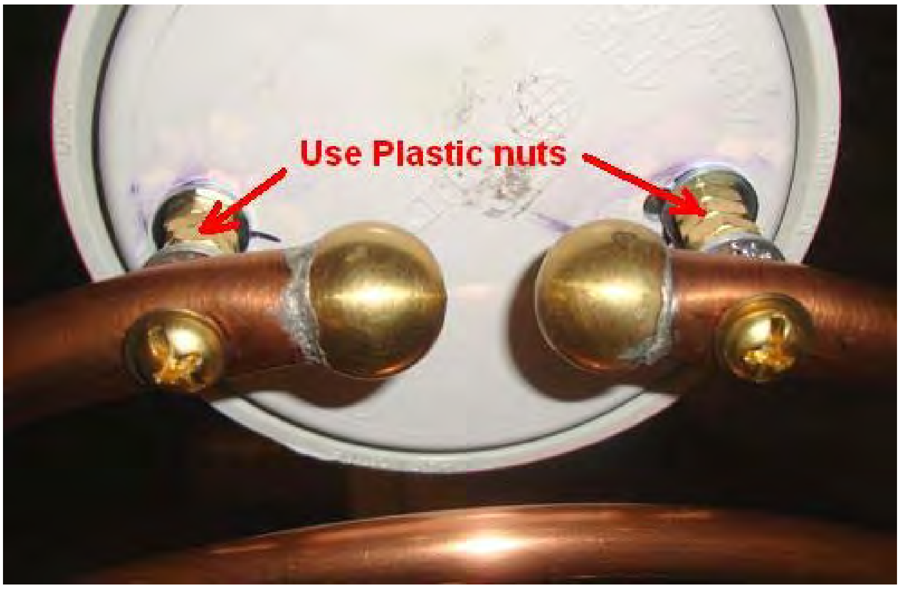
If by any chance one of the copper pipe ends is not perfectly rounded, try to fix the problem with conical pliers and if really necessary, drill another hole one size bigger in the sphere to make it fit. DO NOT push a screw diver into the hole trying to fix the edge around the tube end. The inner end side of the screw driver will push out the copper tube wall, damaging the copper pipe! I used Pipe Tubing Cutter No. 350 (US) professional plumber hand tool for cutting the pipes to fit, and when I got to the small tubes I simply used a metal saw and holding my hand with the tube in it, put my hand on the table edge and cut the needed piece off. After every cut I filed the ends off with fine metal file, finishing with 220 sandpaper.

The following process will demand careful planning; I previously cut off 4 pieces of 1/2" round brass rod, 1" long. I made the two rods to fit into the two open ends of one of the biggest ring. I did not have to solder it because it could never go anywhere. After this I took the first sphere and put them on to the two ends of my first number 1 ring. Of course before all the rings get soldered they have to be cleaned up at the ends with sandpaper and brush on plumbing flux (water soluble, lead free) everywhere around the soldering area. I used the blue BernzOmatic P propane tank, net weight 14.1 oz. I only used the smallest setting on it with a flame size of about 1/2". I always soldered the one on the top. When I finished, about in one minute I cooled heated area down with a cold wet rag, and turned the tube around. I did the same process till I got all the nine rings finished. All my rings are sized correctly between the spheres and ready for the next step. I used fine brass scuffing pad to shine them up, and I cleaned all the rings with ammonia cleaning solution. I put them all back in the template. My spheres fitted perfectly.

I used Nylon Wax Lacing Tape Tying String Size 4 Finish B - 500 yards each MIL-T-43436B. It worked well. I had no idea how much was needed for one side of the cross to finish it, so I pulled off about 4' of the nylon lace. The good thing about this part, there is no way to make costly mistake, if it doesn't look right it can be cut off and started again. Tools needed are; one small pair of scissors, a magnifying glass, and 7-SA tweezers. I started with the number 12 ring which is the smallest of all the tubes, and put three knots on it. I had to pick it out of its place because it is so small, but when I was done I put it right back to its right position. Next, I went under the next tube, turning around the tube and came back to where I went under the tube, I went under the straight lace and came back on top, back through the loop I just made before, I put my finger on the small ring and on the second smallest ring and I squeezed the nylon lace. I basically made a knot over the next tube of number 12 Ring. After this made another tight knot on the same ring! The third time I just went around the same ring without the knot and pulled on the nylon lace. Every time I made a loop on any rings I put my fingers to hold the involved rings down, and I pulled on the lace and moved on to the next ring, went under it and the whole process is repeating itself again until I reached the 6th ring. At the 6th ring all the same, but when I went to the next ring from here on I approached the first contact from the top not through the bottom and the rest is all the same with the top approach till the last ring number 1.

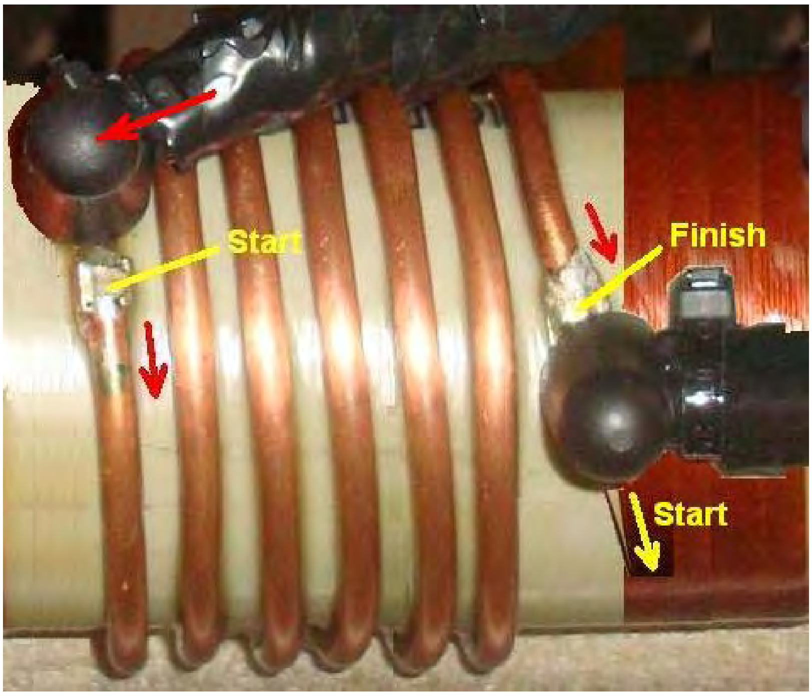
After every turn it is necessary to pull hard on the lace keeping the connections between the rings tight. When the last ring is finished, I went back with the lace to the number 3 ring from the bottom (opposite of what has been done before). When I turned back to toward the number 1 ring, I made a knot on number 3 ring and went straight back on the top of the number 2 ring, made the usual knot again and went to the number 1 ring again on the top and making 2 more tight knots on the number 1 ring. I carefully cut the end off the lace about 1" away from the knot and one side of the cross was done. Next, must finish the opposite of the cross I just finished, so I am pulling on against the side I just finished. This insures the integrity of the antenna gets stronger, by finishing step by step all the cross sides. I finished all 4 sides of the cross grooves.

The completed aerial array is connected in its place with four plastic spacing nuts on each side because if connected with brass like this, you get sparks between the corners of the nuts:

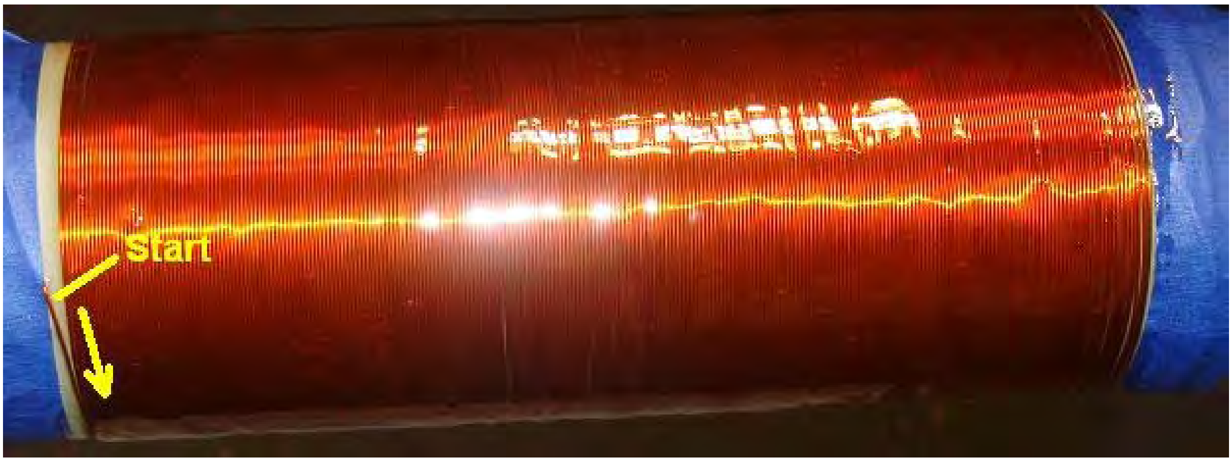


In order to connect up the two aerials, we need to construct two Tesla coils, one for the transmitting aerial connected to the housing and one for the free-standing receiving aerial.

These coils are a bit unusual. They are wound in a “clockwise” direction and they have two separate coils wound on a single former or central tube. The first coil is made with thick wire and is only 6.3 turns long, and these turns are spaced out so that there is a 2 mm gap between each turn and the next turn. The wire is bare #10 AWG which has a diameter of 2.54 mm. The windings take up only 1.25 inches (29 mm) along the former which has a diameter of 2.99 inches (76 mm) and is made of white “schedule 40 PVC” plastic.



Then there is a gap of a quarter of an inch (6 mm) between that thick primary coil and the thinner secondary 330-turn coil which is wound with #20 AWG solid enamelled copper wire with a diameter of 0.81 mm:

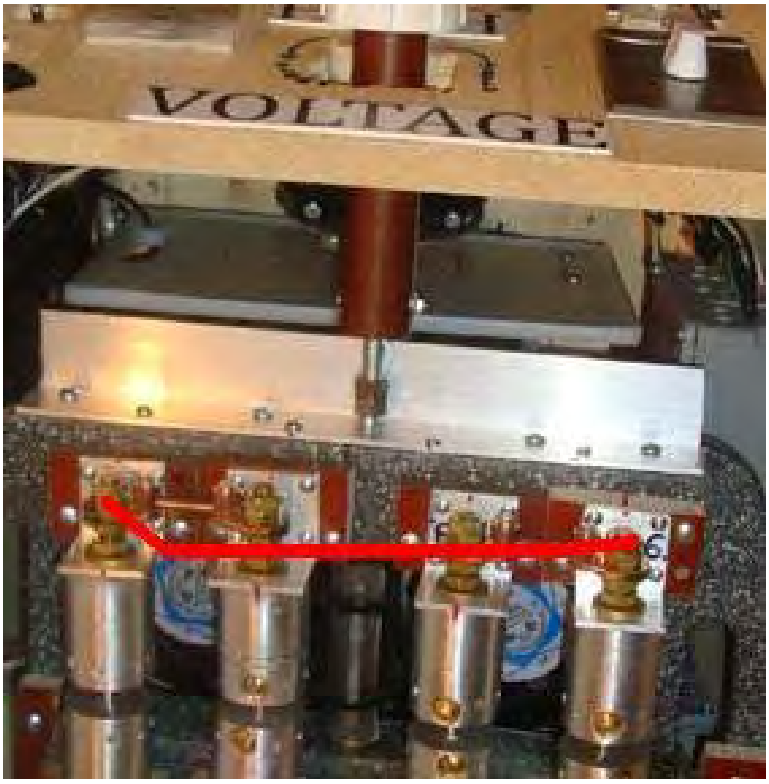


However, the transmitting Tesla coil and the receiving Tesla coil need to resonate at different frequencies, so wind the receiving coil with 350 turns of wire to give it a lower resonant frequency. We want the frequency difference between the two coils to be 100 kHz. Getting that to happen is not all that easy.

This requires the use of a Megahertz frequency oscilloscope and a radio-frequency signal generator. Radio frequency is the range from 3 kHz to 300 GHz. If you happen to own those and are familiar with how they work, then that is excellent. For the rest of us, it is a case of finding a friend who has those, or perhaps persuading a technician at your local university or technical college to help you with the setting up of your machine. Failing that, there may be a radio amateur club in your area and members would almost certainly be pleased to help out.

We need to isolate each coil in turn, so we remove both aerials and the receiving Tesla coil and place they well away in another room. Then we couple the signal generator loosely to the transmitting Tesla coil by taking an unshielded wire from the generator and wrapping two turns around the outside of the coil holder. That signal generator wire radiates the generator frequency and the Tesla coil picks up that frequency and transmits from the thick-wire primary through the thin-wire secondary and on out into the room along that axis.

We pick up that radiated signal by giving the oscilloscope an aerial like a TV indoor aerial. A loop of wire is quite sufficient for this, so place the oscilloscope on a stool or chair in front of the Tesla coil, at the same height and two or three feet away from it. The Lakhovsky machine is left switched off and the spark gap needs to be either fully open or fully closed, so short-circuit the spark gap like this:



Make sure that the Lakhovsky earth grid is connected and then power up the signal generator and the oscilloscope. As the signal generator frequency is adjusted, the signal received and displayed by the oscilloscope increases or decreases in strength. The maximum signal strength is when the Tesla coil resonates with the generator's signal. That frequency is likely to be more than 500 kHz and less than 1 MHz. When you have discovered that value, remove the Tesla coil and put it in another room. Replace the receiving Tesla coil but not the aerial, and prepare to repeat the oscilloscope measurement. We need to make the receiving Tesla coil resonate 100 kHz lower than the transmitting Tesla coil. The receiving Tesla coil's resonant frequency can be lowered by adding more turns to the receiving coil's secondary or raised by removing some turns. It is much harder to add turns to an existing coil rather than to remove turns, and that is why additional turns are suggested on one of the two Tesla coils. That number of turns will be reduced as you tune the resonant frequency of the second Tesla coil.

When you have got the two Tesla coils with a 100 kHz difference in resonant frequency, then both coils can be coated with a suitable material. The easiest is the old-fashioned shellac which is easy to use and dries to a shiny brown coat which acts as a high-voltage insulator. The American developer opted to use a mixture of resin and hardener used for fabricating fibreglass, but that has a very long hardening time and the coil has to be rotated for long periods of time in order to keep an even thickness of the coating.

When the coating on both coils has hardened, the spark gap short circuit can be removed and both Tesla coils and both aerials mounted again. Please remember that you must not use metal nuts as spacers to keep the aerials away from the Tesla coil housings as you will get unwanted sparking between the nuts if you do that. If you have any difficulty in getting plastic nuts of the correct size, then you can just use a non-conductive sleeve of rigid plastic or of hardwood.

Using the machine:

The developer describes using the equipment like this: My machine is set up in the room, so that it is close to the area where my ground rods are located outside. The machine is aligned along a North - South axis, with the transmitter aerial attached to the housing being on the North side.

I positioned the two antennas 31 inches (790 mm) apart. We are all different sizes, so there should be 8" (200 mm) between each antenna and the body. I don't adjust them any more, if I'm sitting between the antennas, shoulder to shoulder I have 200 mm between me and the antenna, and if I stand up and I turn sideways between the antennas I just position myself in the centre of the two antennas. I never touch the antennas when the machine is operating and I don't touch them for 30 minutes after using the machine. If I have to touch the antennas immediately after testing for any reason, I make sure that all capacitors are discharged!!

I use an all wood stool to sit on (21" high x 13" width) if I sit during treatment. I remove all metal objects off me before I use the machine and I keep them far away so that they will not interfere with the performance of the machine. I put my wood stool on the top of a plastic sheet 44” x 27” x 2mm thick. I try to avoid having anything metal in the treatment room, and I have NO metal anywhere within 4-feet around the machine. The emergency foot-operated shut-off switch allows me to power down the equipment completely if something is not right. I always check my antenna distance and I always do a visual check before I start using the equipment. I have a great respect for the power it takes to run this machine, I never forget the fact that it can certainly heal me, but if I am not careful it can also kill me.

I personally do not have any disease or any major physical problems. I built the Lakhovsky machine to prevent illness before it could happen - sort of like having my own insurance, rather than paying for the expensive Obama Care.

First I let the equipment run continuously over 1 hour for testing, to see how all my connections are holding up, and waiting for any sign of high voltage problems like burning wire, sparking, or anything that would compromise any level of safety. Every 10 minutes I turned the Variac transformer to a higher voltage to see if at maximum power still everything stays normal. My machine worked as expected.

Starting the equipment is very easy. Plug in the main power to the wall outlet. Making sure that no window air-conditioning unit, any electric motor or computer is running nearby. I have a fused Power Socket Surge Protector Strip Plug Extension Cord 3ft long and I plug my equipment in to that and then I plug the extension cord in to the mains supply socket. Then I turn on the main power switch on the housing control panel. I then turn on the Timer switch to the desired time, which activates the cooling fans, neon light, and the Variac transformer.

The voltage adjustment very much depends on what size of high voltage transformer is installed in the equipment. The higher the Neon Tube Transformer module output voltage, the lower is the voltage needed to run the equipment. Mine is a 12,000-volt module. I adjust the voltage to about 40-50 volts as shown on my voltage meter. My spark gap turns on around 30 volts and start to be giving more constant sound the more I keep turning the voltage higher. When I have turned my Variac transformer up to the voltage I want, I never need to adjust it any more, but I am using the machine for maintaining my health and keeping my immune system "charged". So, for that I adjust the NST output voltage to 3700 volts and I adjust the spark gaps to give 3 amps on my ammeter. More than enough for most of the maintaining health and less serious conditions like cold or headache.

For more serious medical conditions, the NST can be adjusted to 4000 volts and between 3 and 4.5 amps for deeper penetrations in the body. Care must be taking to insure the problematic side facing the transmitter antenna. For very sick people or for a child, you should use a lower adjustment and a shorter treatment time, like 3400 volts and 2 to 2.5 amps with 10 minutes of running time.

The equipment is of great value for dogs and cats too, but for them adjustment should be around 3000 volts at 2 amps for a maximum of 10 minutes or less for cats and small dogs. When I adjust the voltage and amps to the desired ampere if I hear a breaking up sound from the spark gaps I just turn the Variac knob to slowly raise the voltage until the equipment's spark gap is giving out a nice continuous sound - when this happens everything works right. I sit between the antennas until the adjusted manual timer turns the equipment off. Do not touch the antennas.

When I am done, I turn off the switches and I always unplug the equipment after every use. I usually turn my timer to 15 minutes. Sometimes I use it twice a week some times I use it every 3 days or just once a week. It depends on how I feel. According to experienced operators, the best results can be achieved by using the equipment every 4th day.

I also drink a big glass of water with 1000mg of vitamin C (non-acidic sodium ascorbate) in soluble fine crystals form, mixed in the water. I drink another 8 ounce glass of water right after when I am finished using the equipment machine.

Personal experiences:
I love my Lakhovsky machine! "Can't live without it!" I don't know that I found the sweet spot maybe with my adjustments on my machine that resonate with my body composition but it works on me just great. I know this because in less than 7 minutes it calms me down like no kava or xanax could. It's just a miracle how it can affect me and still after all this time I wonder how this is possible even if I understand the principle of the machine. I never get cold or sick any more. After the machine been used, it makes me feel relaxed all day long and just feeling that general well being, with uplifting like everything is great.

I have a routine usage of my machine. Most of the time I use it every 4th day around noon when the sun is highest above me. I start my cycle by putting the antennas at my head and neck position, shoulder to shoulder position, so my liver is on the transmitter antenna side. I do 15 minutes. This is my set up that is the most powerful for me. I feel calmness in 5 to 7 minutes. Four days later I set up my antennas to my back & front standing up (no wood stool) around where the kidneys are facing the transmitter antenna. I do 12 minutes. Four days later, I position myself the same way before but at this time my abdomen area facing the transmitter antenna. I do 15 minutes. I finish my cycle four days later by positioning my antennas to my legs when I am sitting on my stool shoulder to shoulder, liver facing the transmitter antenna. My cycle is done and I take a week off and then start my cycle again same way or randomly how ever I feel about it.

I see many people paying for Rife tubes to use them with the Lakhovsky machine which cost thousands of dollars of additional money. I think it is a waste of money! I use MMS to kill pathogens in my body! It works and cost pennies to make it! Taking everything into account, I am very satisfied with my Lakhovsky machine!

Disclaimer:
Please understand clearly, that this text is for information purposes only and it must not be construed as being an encouragement to make or use any such equipment. Should you, in spite of this warning, decide to build and use any such machine, then you do so entirely at your own risk and on your own responsibility, and nobody other than you is in any way responsible for your actions and the resulting effects.

Also, if you are not already familiar with working with high-voltage circuits, then please do not do so unless under the supervision and guidance of a person who has experience with these kinds of circuits.

Please note that nobody who has a pacemaker or any similar device, should come within ten metres of this machine when it is switched on as the pacemaker or device is likely to be affected by the radiation coming from the machine, and that could result in death.

It has also been commented on that the electromagnetic radiations from a Lakhovsky device can damage computer and other similar circuitry if not kept well away from the machine. A distance of one metre is the absolute minimum distance and a distance of ten metres is to be preferred.

This equipment produces a continuous spark in the same way that a MIG welder does, and so there is a similar visual hazard. However, as the spark gap is inside the housing, just ensure that the door of the housing is kept closed when the machine is in use.

Finally, as already stated in the text, capacitors can hold lethal levels of charge for a very long time after the equipment is disconnected from the mains. This must be allowed for, and it is good practice to connect a high-value resistor across any high-voltage capacitor, so that the charge will be siphoned off reasonably soon after power-down.

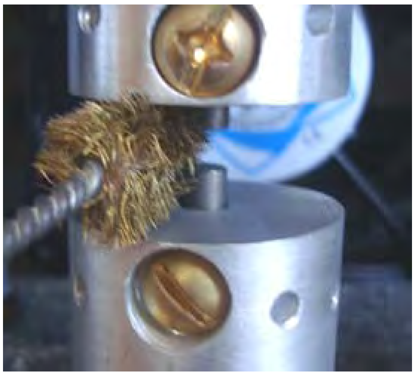
Since writing this, people have made copies for themselves and they and their friends have experienced great medical benefits from this equipment.

2017 Update

The designer of the Lakhovsky equipment shown above has made some improvements and comments in March 2017. He says:

Additional capacitors: I have updated my two capacitor banks from the original 15.9nF /15KV to 21.2nF /15KV. For this, I installed one more 5300pF /15KV capacitor to my already existing capacitor bank. I added one more 5300pF /15KV capacitor into the parallel connections with the rest of the capacitors in each bank. So, each side now has four 5300pF /15KV capacitors. I did this for smoother operation, more vibration and having more "punch" at the end of the antennas.

Cleaning the spark gaps: After using the machine for ten hours, I clean the spark gaps because they will have built up white residue deposits which interfere with the smooth operation of the spark gap as a whole. With the machine unplugged and the capacitors discharged, I open the spark gaps as much as possible. I use a brass rounded brush to clean the surface area



around the tungsten rods and the aluminium which is holding the rods. When that has been completed, I use a small file and gently file the end of the two rods until they shine again. Then I blow them off with an air can cleaner for keyboard cleaning, unless compressed air is available, and finally, adjust the spark gaps to the desired gap size.

Adjustments during use: I have repeatedly tested different spark gap distances and higher or lower voltage adjustments in order to find the best healing results for the body. I found one spark gap setting that felt better for many applications. I believe that the smaller the spark gaps, the higher the "quality" of vibration at the antennas. I found that many experiments were much better if I adjusted the spark gaps to 0.20 mm drawing between 3 and 4 amps. I'm using a transformer which has a 120V input and a 12,000V output, and able to provide 60 milliamps of current. This is an old style Neon Tube Transformer, with the mid point of the output winding grounded.

I also believe that I should not lower the current below 3 amps unless the machine is being used for sick small children or very weak old people or dogs and cats! I control the treatment intensity by timing the sessions. Also, I "discovered" that sometimes the time is the most important adjustment of the session. I believe that there are days when the person needs more or less time, very much depends on stress level of the person, food intake of the day, liquid consumption, and how much sugar, dietary carbohydrates was eaten on the day of the treatment.

I came to realise that it is not good just to say: “use the machine for 15 minutes per session”. I actually found that my best times were around 17 minutes for upper body treatment between the neck and the hip, back and front, 12 minutes for legs, 15 minutes for neck and head from the two sides. All these data time are for the antennas set at a 200 mm distance from both sides of the body.

My experiments show me also, that you can actually over stress the body with too long operation of the machine, if you located directly between the two antennas, as the healing energy directly between the two antennas.

Each person is unique in every way as possible so, I recommend that each person should find the right time for himself by starting for the first time with a 10 minute session, and then keep adding 1 minute per session, keeping 3 days between sessions. Also I would recommend making notes of every session recording the duration in minutes, current used, voltage level, field intensity level between the two antennas, antenna gap distance, date, time of day, body part facing the transmitter antenna, notes of any feelings good or bad, anything that helps monitor healings of the body.

These notes help me to make better adjustments and give me guidance for best usage of the machine. When you keep adding the 1 minutes to find out how much time would be best for you, pay attention for nervousness, next day muscle strain where the transmitter antenna was pointed on the body, unpleasant feeling at the end of the session or during session. When this happening make a note of your duration time and do another session in 3 days and see that if it happens again. If it does, then reduce your duration time by 1 minute, and most likely you found your best time on that area of your body.

This is of course how I do my experimentation for myself, everybody should use common sense. What works for me may be unpleasant for somebody else. And of course after few months of using the machine, you will need less time per session because now your energy level will be charged up to a much higher level than it was when you first started. During the first month of treatment I did not feel anything in 20 minutes use, only some tingling here and there. The body will learn from the changes and will adapt slowly for better or worse symptoms. The challenge here is to be able to recognise as quickly as possible if the change in or on the body is worst or better and make the appropriate correction immediately! What I consider to be a ‘better’ change is feeling generally better, skin getting smoother, nails are growing noticeable faster, hair feels stronger, better sleep, eyes are whiter if it was stressed before with lots of red line or yellowish colour (which is always the symptoms of a stressed out liver), if pain is present, then it should start going away with every new treatment session. ‘Worse’ changes are you feeling stressed out, feeling light pressure at the head, light soreness in the muscles, If these symptoms were not present before you started using your machine, then your machine is not built right or it's not tuned right, or quite simply the antennas are not positioned at the right area of the body, or you are over-using the machine.

Sitting or standing: I do realise that most people may be motivated to build this machine because of an illness which they have and they may find it difficult to stand up for 15 to 17 minutes. For people who can't stand up safely, they need to do the best that they can. I hardly ever sit down on my wooden stool unless I am doing neck and head session. I think standing is the best position if you are lucky enough to be able to stand and so can pull the two antennas closer together. When standing, it is easier to position the transmitter antenna on the desired location of the body! Chairs with their arms, get in the way between the body and antennas. I know it's not that much of a restriction because the healing rays will pass through the chair but I want maximum exposure as much as possible. That's just how I think. So, I prefer to stand so that I can get the antennas closer together for maximum field intensity level.

Diet: I tried many ways to see how, in what physical condition is the best to use the machine. I do not use my machine with an empty stomach. I prefer to use the machine around noon, but that's just me. I remember at the beginning I felt dizzy and fussed when I used the machine with an empty stomach. I believe that the very same day, same night when I use the machine, immediately after the session started working in the body so, in my opinion the body uses lots of energy to start the healing process. The worst thing that you can do is to put too much food in the body after using the machine. The best way to help the healing process is to lower your calorie intake and eat higher quality food.

Here is my amazing food combination recipe for the day after the machine was used. I highly recommend it. It has been tested for years and IT WORKS. It will speed up the healing process and help to detoxify the body. This combination of food addresses all the need for all organs in the body. It can be eaten as the only food source for 3 to 7 days as a detoxifying diet. I did it once for 5 days, and it is unbelievable how fast the human body responds positively to the right food! Here we go.......

In a Vita Mix or in a blender blend the following until you have a paste.

1. 20 blueberries
2. 1 orange slice
3. 1 whole banana
4. 3 strawberries
5. 1 half an apple (red or green)
6. 20 raw almonds (or raw walnuts)
7. 10 grapes
8. 1 thin slice of onion
9. 2 pinches of cinnamon

Make 10 ounces (0.28 litres) of the above mix for one day. You must drink 80 - 120 ounces (2.25 to 3.4 litres) of water the same day with the paste food.
Eat your paste at the following rates:

Breakfast: Eat 60% of the paste food
Lunch: Eat 30% of the paste food
Dinner: Eat 10% of the paste food

The paste should be eaten alone with nothing else in the day after the machine was used. Even if you do this for only one day after using the machine, it will be extremely beneficial.

April 2017:
The author on whose information and experience this Lakhovsky equipment description has been based, wishes to share his insight, much of which has been gained from the book "Diagnostic Face Reading and Holistic Healing" by Roger Bezanis which he considers to be a masterpiece and which he recommends very highly. The paperback version of the fifth edition of that book can be purchased from Amazon in America for $48.95 plus postage, or from Amazon in UK for £82.45 plus postage.

After considering what the book has to say, he says: Know what you are! Health is freedom. Dr Alex Karrel, the Nobel Prize winner who kept a chicken heart cell alive for 34 years, said: "The cell itself is IMMORTAL. The key point is the liquid medium, (water) the cell is in, and in which it degenerates. If you renew the medium periodically, and give the cell all it needs for nutrition, then the beat of life can last FOREVER."

"Our body is an energetic organism made of material or mass! The ideal balance is where Equal Mass = Equal Energy. In any structure, such as the human body, when there are equal amounts of mass and energy present, a state of optimum health is the result and balance is achieved. When there is an OVERABUNDANCE of Mass or Energy, then the body gets sick and can die. If an imbalanced condition persists long enough, without fail the body will die.

Please understand that bodily organs are overwhelmed if there is too much Mass or too much Energy! Any organ or organ system that can process mass or energy waste at its optimum capacity will fail and eventually will shut down. Cancer is a mass that is not interfacing with, and not being monitored by, Energy! Any health remedy for a so called cancer must at its root re-establish the FLOW OF ENERGY and mass at the affected part of the body!

The body must be in communication with itself at every level 100% of the time in order to survive at an optimum level. ALL LIFE IS DEPENDENT UPON THESE FACTORS. This is where the Lakhovsky machine comes into the bigger picture. This is why the Lakhovsky machine has been so very successful in the past. Why has this machine been suppressed for over 80 years now? The Lakhovsky machine is able to start the flow of energy again at any affected area of the body.

Pain is always a sign of an abnormality or problem point in the body, but pain is not necessarily telling us the true cause of the problem. I could write 1000 pages about how the complex human body works and still I would just be scratching the surface of the problem. So, I think that the best way to show ‘the elephant in the room’ is by telling you what I do, and leave it up to you, the reader, to choose what to do with the information that I am sharing, with a pure heart and based upon my own experience.

I look at the body and in my mind there is a map of the location of every organ. I highly recommend that you to go online and look at some pictures which show the human anatomy in detail. Your success with a Lakhovsky machine depends on it. Arm yourself with the understanding of where all organs are located in the body! I spent thousands of hours studying human health and the causes of failure, and I can tell you with certainty that it is not nearly as complicated as I thought it was at the beginning.

You need to understand, as a Lakhovsky machine operator, what the Liver and the Kidney control in the body. I only focus my antennas to liver, kidney, heart, colon, and head. After that, if there are still no signs of any positive results after 8 to 10 sessions, I would start targeting the rest of the body where pain is present and still keep up with the liver or kidney too.

I think that it's clear that if one has a colon problem I would target the colon, same goes for the heart and head, but when it comes to Liver and Kidney it is a totally different ball game! The Liver and Kidneys are the master organs in the body! Let’s see what they control in the body and you, the reader, (and possibly machine operator) will see clearly why I want you to know this priceless information, so that one day it can save your life.

Liver:
Liver and emotions are linked.
Coughing
All bad moods
Emotional stress
Watery eyes
Itchy skin
Migraines headaches like all headaches are product of the liver being overwhelmed.

The Liver regulates:

- Skin
- Lungs

- Sinuses
- Nasal cavities
- Colon
- Intestines
- Uterus
- Mouth
- Tongue
- Gums
- All hollow organs

Kidneys:
The kidneys regulate:

- Uric acid
- Lactic acid
- Urine production and removal
- Mucous distribution
- Blood flow, i.e. blood pressure
- The heart
- The ears
- Fingernails
- Hair
- Most muscle groups
- Reproductive system
- The scalp
- Fluid of the eyes
- Fluid at the colon
- Waste water from the colon
- Waste water from the liver
- Water distributed to the liver
- Most joints (except the right shoulder region down to the right elbow)
- Pancreas
- Lymphatic system
- All non-hollow organs

The Kidney regulates most of the left side of the body, and the Liver regulates the right side of the body, so armed with this information the body tells its own story. If the problem is on the left side of the body I would focus on the kidney as the root of the problem. If the complaint is on the right side of the body, I know immediately that something is "fishy" with the liver.

This means that a cancer (just an evil word for toxic mass) that shows up on the outside (or inside of any organ this includes melanoma) is a Liver problem! Handling any problems such as "surface cancer" as a Liver problem, always solves the problem. On the other hand "deep tissue cancer" is basically a Kidney problem. If one addresses each problem correctly with the Lakhovsky machine, then the results will be excellent every time!

REMEMBER, YOUR BODY NEVER LIES. TRUST ITS SIGNALS AND YOU WILL BE HEALTHIER.

Alzheimer’s Disease

At http://emediapress.com/2016/12/18/mit-reverses-alzheimers-with-40hz-blinking-lights/, half way down the page there is a recording which when listened to using headphones, is claimed to reverse Alzheimer’s disease. The recording runs for 30 minutes and using headphones is essential as the sound input to the left ear is different to the sound input to the right ear. Whether or not the recording is effective, I have no way of knowing, but I have no reason to doubt the claim. It is also recommended that the supplement Lecithin and the supplement MSM, both taken daily can also oppose the onset of Alzheimer’s (one possible supplier is www.ZipVit.co.uk).

The World situation.

The late Dr Hans Rosen made an exceptionally good presentation on world population, world health and world income. Spanning a period from 10,000 years BC to the year 2100, he has made many people aware of the current situation and pointed out the average person's extreme lack of knowledge on the subject. He points out that the critical birth rate is now around 2.2 children per family as opposed to the 5 children per family average which caused the world population growth. At this point in time, there are about 2 billion children in the world, but that number has stabilised out and is now roughly constant. Yes, the overall population will rise from around 7 billion to around 11 billion due to the present population aging, as is normal.

Hans also points out the financial situation for people generally. He uses the American dollar as a unit for comparison and states that the richest billion people earn about $100 per day and the poorest billion people live in extreme poverty, earning about $1 per day. People in extreme poverty cannot be sure of their next meal, and most do not have clean drinking water, medical services, electricity or education. Putting those income levels in annual amounts, the richest one billion people receive US $36,500 (or more) per year and the poorest one billion people earn just $500 (or less) per year. It is highly likely that you didn't realise how very well off you are compared to more than one billion other people.

In his book "Doing Good, Better" (available free from http://audiobookle.com/), William MacAskill debunks the general notion that "I can't do anything about the world situation – I am only one person". If you live in extreme poverty, then that is probably true, but if you are one of the richest one billion, then that is so not true. If you were to donate just ten percent of your income on a regular basis, then you could make a major difference to those people whose income is only one percent of your income. Even a lesser level of regular donation makes a major difference, and that major difference is caused by you personally.

William examines the facts and points out a number of things which are disconcerting, such as the fact that donating to a good charity is not nearly as effective as donating to the very best charities, that is, those charities whose work produces the very best results as shown by subsequent, independent examination. Some of those charities are shown here:
https://www.thelifeyoucansave.org/Top-Charities?utm_source=top-icon&utm_campaign=homepage&utm_medium=all

Extreme poverty is self-sustaining as people trapped in that situation live in such poor conditions that they have large families **because** most of their children will die as young children, many before the age of five. In fact, some 2000 poor children die every day, and I leave you to consider the level of unhappiness that is caused by those family deaths. Regular donations from you (and from me) do make it possible to move these people permanently out of extreme poverty. It is actually 100 times more effective to donate to those poorest people than to donate to the needy in your own advanced country where the neediest would be considered to be 'rich' by the people in the poorest one billion. You and I are very rich by comparison to those people and it is an interesting question to ask what it was that we personally did to be born into such a wealthy situation.

It is most interesting to note the charitable activities which have proven to be the most effective. One is called *Give Directly* and it gives a cash sum of $1000 to a family, leaving it up to the family members to use it in the most effective way for the family. That technique is very effective as the family is in great need and will definitely not waste the asset, but instead will buy what will help them most in the future.

Another effective charity, most surprisingly, makes radio broadcasts. That is the *Development Media International* group and it educates the very poor on health and hygiene matters. You would think that doing that is unnecessary, but the poorest people do not know even the most basic things such as washing hands before a meal.

The *Evidence Action* charity works on providing safe drinking water and combating intestinal worms which cause illness which can kill and which if not too severe, prevents children attending school.

The *Against Malaria Foundation* provides insecticide-impregnated anti-mosquito nets to go around beds. These nets are very cheap and are effective. William MacAskill prefers that you donate to cancer research as more people die of cancer than die from malaria, but that really puzzles me as the very cheap and well-proven colloidal silver treatment can cure both cancer and malaria. Is it a case that the Cancer Research people just don't know about it, or is it the case that they just want to get paid to do research?

Chapter 23: Reversing Genetic Modification

It is not widely known, but the universe is powered by the zero-point energy field and all life forms are powered by an intelligent life force which has been called by different names by the men who discovered it and learned how to use it. Perhaps the most widely known name for this force is “Orgone” and it can be concentrated and directed by certain physical shapes as described by Dan Davidson in his book *Shape Power*. The force has unlimited power and with a concentrator made of concentric stainless steel pipes called a Joe Cell, it can power a vehicle without the need for any kind of fuel. With a concentrator shaped as a pyramid, it can preserve foods, discourage harmful insects, or recuperate old or sick animals. With a small and simple electrical device it can affect the weather up to a thousand miles away.

In recent years, Mehran Tavakoli Keshe (pronounced ‘Kesh’) has developed another, powerful way of concentrating Orgone energy through the use of processed water. Keshe has invented a range of new names for different parts of his various processes and as these new names are unfamiliar, they have made his techniques difficult to understand. He has produced devices for dealing with ill health and injury, accessing Orgone for power production, and techniques for dealing with growing food and other plants where the conditions are difficult. This last item is particularly important as it is capable of overcoming defects in grain and so can restore grain to its original, robust form. This is important as Genetically Modified “GM” or “GMO” alterations to grain are effectively ‘defects’ as far as the original grain is concerned and so the process can remove the “GM” alteration and restore the grain to its original robust state. This can be accomplished by soaking the grain and keeping it near Keshe’s modified water before planting the grain.

This brings us to the Keshe modifications of water. The technology is confusing for newcomers as there are several different ways of producing Keshe modified water, each with a different outcome and different potential applications. The term which Keshe has invented for all of these modified waters is “GaNS water” where “GaNS” is his term for a material produced during his treatment of water.

This is a new technology and I am not yet expert in it, but as far as I am aware, in the most simple broad outline, the procedure is:

1. You make a GaNS electrode by immersing copper wire in cold, diluted caustic soda for two or three days. Caustic soda is dangerous stuff, so you wear gloves and goggles when working with it. The wire is then rinsed off in distilled water.

2. You perform electrolysis on water containing sea salt (from your local supermarket), using your GaNS-coated copper electrode and another electrode made of zinc, (or copper, iron, or whatever). That produces genuine GaNS material in the container.

3. After a 24 to 48 hour period of zero-applied-current electrolysis the electrode plates are removed from the container which is then left undisturbed for a further 24 to 48 hours, during which time the GaNS material sinks to the bottom of the container.

4. Pour off most of the water (keeping it for re-use in case you want to make more GaNS material later). As the GaNS material is mixed with the last little bit of your sea-salt electrolyte, you need to add distilled water to the container, agitate the contents gently and after the GaNS material settles again, pour out as much of the water as possible.

5. That rinsing off process is repeated for at least 5 times and preferably 10 times in order to get clean, salt-free GaNS material.

6. The GaNS material is very valuable. It has indefinite life and can make any number of sets of GaNS water by filling the container with distilled water and leaving it there for at least 24 hours. The resulting GaNS water has spectacular properties. Fifty ccs of the water in a bottle left floating in 24000 litres of water energises the water with Orgone and makes an enormous difference to an aquaphonics farm. When placed in a plastic tube it feeds Orgone energy to growing plants (or to humans). I know very little about Keshe technology which is unfamiliar to say the least. Remember that you can make as much GaNS material as you want AND you can make as much GaNS water as you want from every dose of GaNS material that you make.

Using a carbon rod for one electrode in the electrolysis does NOT produce GaNS material. The “GM” Genetically Modifications made to seed can be reversed by placing the seed in a bucket of water and floating the bucket in a container of GaNS water for 24 hours. The GaNS for this work is made with zinc as one of the electrodes.

1. Now, expanding the detail on these steps it must be understood that the basic process for making any variety of GaNS material requires the use of one GaNS coated electrode and one contributor electrode of a pure metal. The most commonly used metal is zinc which produces what is called ‘Carbon’ or ‘Carbon Dioxide’ GaNS. The initial task is to get a GaNS-coated electrode. These can be bought from places such as chriz (dot) baker (at) hotmail (dot) co (dot) uk or you can make one yourself. There are various methods for the GaNS plating of a copper wire or plate.

The most common processing is done by immersing the copper in a caustic soda (Sodium Hydroxide) solution and leaving it for two or three days. Some people prefer to start the process with heat and then leave the solution to cool as the process continues. No matter what the chosen process is, you definitely need to wear protective gloves and goggles as caustic soda is serious stuff, especially when hot:

If a copper plate is being treated, then both sides need to be in contact with the caustic soda solution, so to achieve that a low table of wire mesh is used to hold the underside of the copper plate clear of the base of the treatment box. When the processing is completed, the copper plate will be black on all faces.

2. When the copper electrode is ready and completely black all over, rinse it off using clean water, holding the plate in a pair of pliers. You still need gloves and goggles when doing this and when disposing or storing the caustic solution for use again.

Originally, sea water would have been used in the next step of processing, but nowadays, due to contamination, it is recommended that a mixture of distilled water and dried sea salt is used instead.

The salt concentration is not at all critical but I would suggest that 10% salt by weight as an absolute upper limit. The processing method is to suspend the GaNS electrode about 70 mm away from a zinc plate with both supported in the salt solution. The two electrodes form a battery in the salt solution and so a short-circuiting wire is connected between the two electrodes using either a soldered connection or a crocodile-clip wire. In either case, the connection must be kept out of the water in order to avoid the process being altered by the metal of the clips or solder. A current will flow along the short-circuiting wire due to chemical action.

No electrical energy source of any kind is applied to the plates, but the required processing continues slowly on its own. Keshe is not joking when he says that patience is a major requirement when making GaNS. When the processing has continued long enough (probably 48 hours), the GaNS material is left floating on the surface of the water and the electrodes are removed from the salt solution.

3. When left alone, the GaNS material gradually sinks to the bottom of the container and is left alone for a further 24 hour period.

4. The water used in making GaNS is salty and so it is poured off very carefully and replaced with distilled water:

5. That water replacement and pouring is done several times to remove the salt, and finally, the container is filled with distilled water and left for 24 hours during which time the GaNS at the bottom of the container charges the new water with Orgone energy, turning it into “GaNS water”.

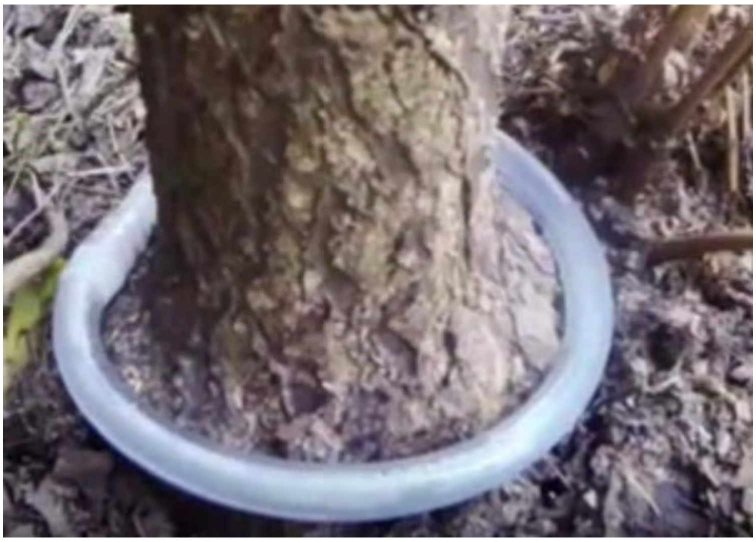
6. This GaNS water is what can return seed to its original state. The water can also be used very effectively in growing vegetables and fruit, reviving dying plants and causing major improvements in the size and quantity of produce treated with the water when growing. Obviously, during the period when the GaNS water is gaining its extraordinary power, other containers can be processed in order to increase the amount of GaNS material available for use and a good deal of GaNS water is needed if farming levels of seed are to be treated before planting. A recommended method for treating grain is to place the grain in a bucket, top up the bucket with water and place the bucket inside a larger container filled with GaNS water. After twenty-four hours, the enhanced grain is ready to be planted. The GaNS material remains potent for weeks and can be used to charge up many, many jars of distilled water to produce GaNS water ready for use.

In passing, it should be mentioned that in all likelihood, a pyramid erected over a sack of grain should have the same effect in returning the grain to its original healthy state. For that, it is only necessary to have the eight straight edges which form the pyramid, as the sides can be left open since the Orgone energy flows along the edges. One of the straight base lines of the pyramid needs to be exactly North-South in direction and by “North” what is meant is Magnetic North which varies gradually every year, and so a compass is used to determine the exact alignment. There are more details in chapter 9.

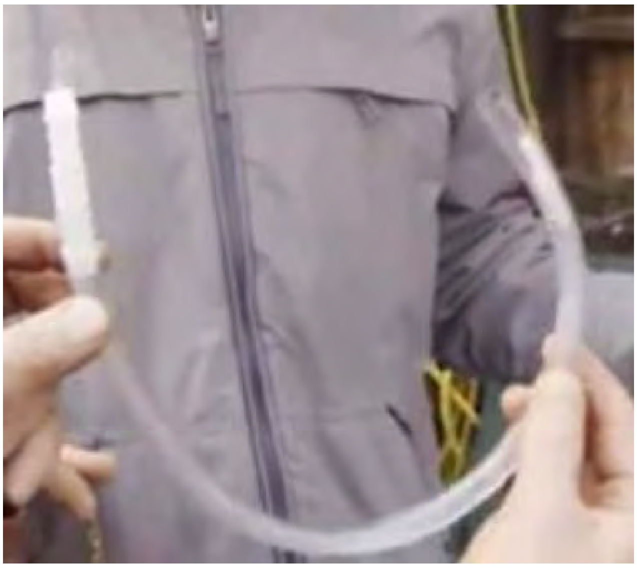
Sodium Hydroxide is sold as “Lye”, “drain cleaner” or “Caustic Soda”. Please be aware that caustic soda is highly dangerous and pouring hot water on it is a potentially reckless thing to do. Consequently, great care needs to be taken when doing that – using a covered container with the lid covering almost all of the top of the container before the hot water is poured in. Have vinegar to hand in case of accidental exposure to the caustic soda, wear protective gloves and goggles, and place the lid back on the container as soon as the water has been poured. Do not breath in the steam which occurs when hot water is poured on caustic soda.

There are various videos worth watching: https://www.youtube.com/watch?v=iRQfYtSHFiY&t=93s or https://www.youtube.com/watch?v=DLMC3AYmUJg&t=393s or https://www.youtube.com/watch?v=l-u7RLuDNfQ . Essentially, keeping your material to be plated in a caustic soda environment for a long, long time is the most important factor.

It needs to be understood that “GaNS water” has a strong Orgone concentrating effect. That effect can be used most effectively by various techniques for vegetable and fruit growing. A pyramid has been shown to draw the groundwater table up towards the surface of the soil, and if the pyramid is large enough and made from the best materials, the water level can actually exceed the ground level. It is likely that the same effect happens with a loop of plastic pipe filled with GaNS water and placed on the ground. That method of filling a plastic tube ring with GaNS water in order to enhance the Orgone flow around a tree is used like this:

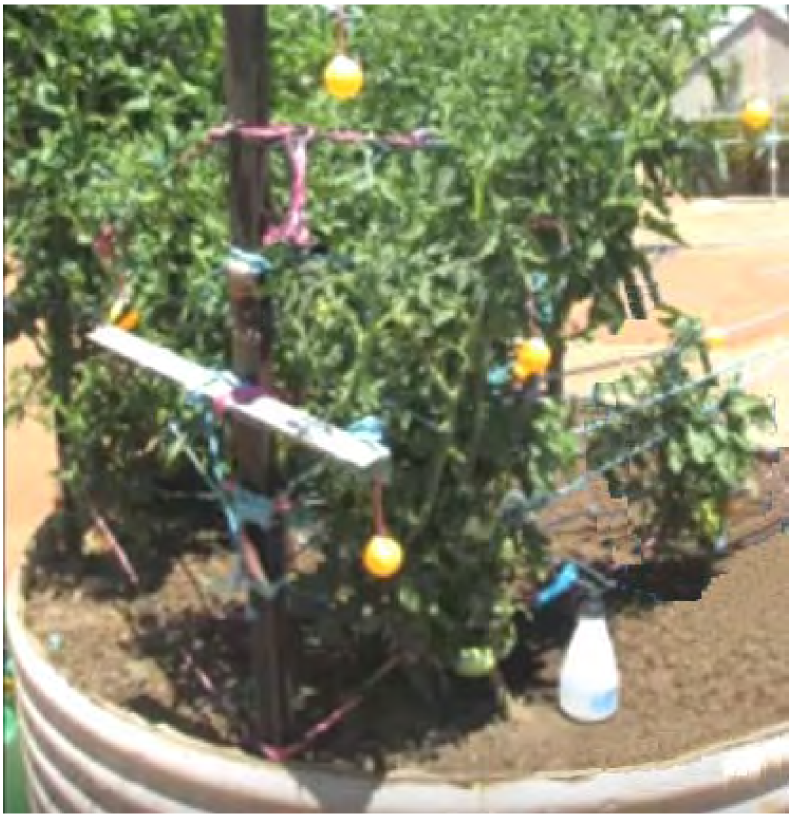


For this, a piece of hollow plastic tube is used to connect the ends of the tube after it is filled with the GaNS water:



In the example above, a smaller diameter tube has also been used, and the smaller tube has been filled with copper GaNS water which is made by substituting a strip of copper for the zinc metal when making the GaNS material. Copper GaNS water is considered to be different to Carbon GaNS water and although with different salt concentrations the resulting colour can be light blue, dark blue or brown. However, Carbon GaNS water is recommended for most plant-growing work.

For example, this container which is being used to grow tomato plants, has small yellow plastic spheres filled with GaNS water suspended around the plants:



You need to understand that there are many possible variations when using Orgone energy with growing plants and this particular gardener uses Carbon GaNS water in the lower spheres and Copper GaNS water in the spheres which are hung higher up. The idea is to generate an increasingly powerful

Orgone field as the plants grow higher. In this instance, the effect of the orgone flow around the tomato plants spills out sideways and enhances the growth of other plants growing in the ground near the tomato container. The gardener waters his plants with water which has been stored for some time with GaNS containers floating in the water. Other gardeners who use GaNS water spheres also insert a small coil of GaNS coated copper wire inside the spheres in the belief that doing so will enhance the Orgone concentrating effect of the spheres.

So, to recap, the effective material used is GaNS water. That is very clean water which is left for 24 hours on top of GaNS material which has been rinsed off many times after creation. The GaNS material itself is not used directly in spite of the fact that it stays active for many months and can make great quantities of GaNS water. I'm told that GaNS water can also be used in many health-related treatments, but that is not the subject here. The GaNS material should never be touched with bare skin, nor should it be eaten.

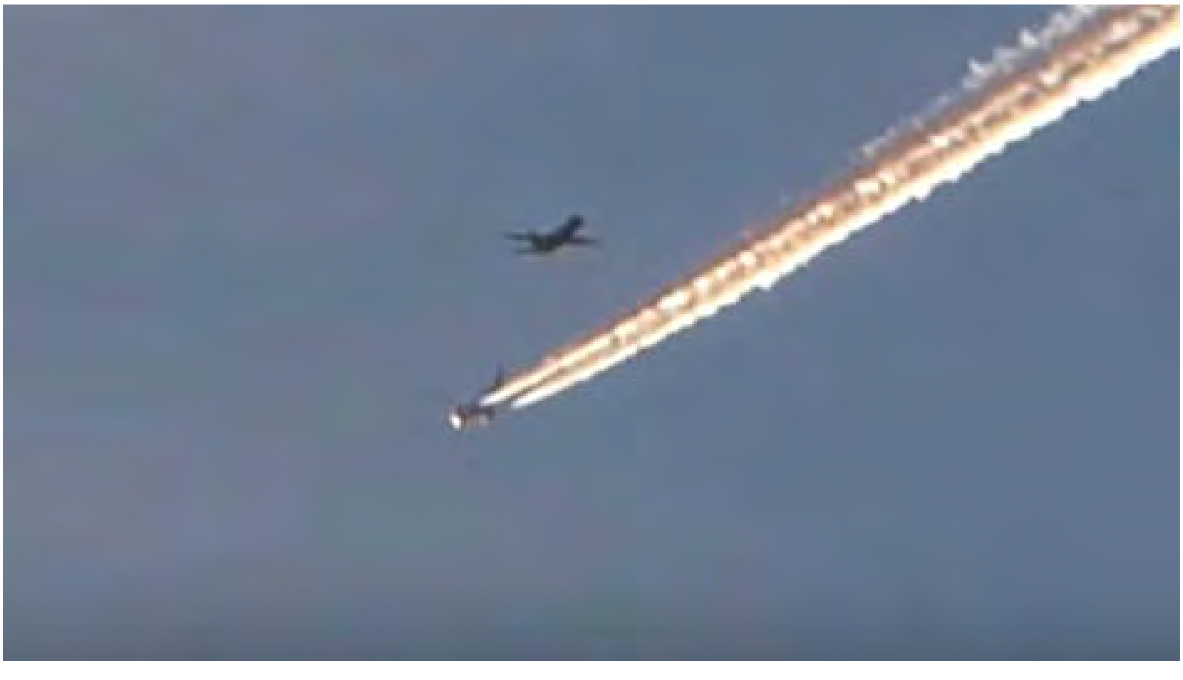
Chapter 24: Dealing With Chemtrails

For many years now, aircraft have been used to spray tons of chemicals into the high atmosphere. Initially, the result looks like a harmless vapour trail in the sky, but it is not. Instead, the material sprayed is highly toxic and intentionally destructive, being a mixture of aluminium, heavy metals, radioactive particles and worst of all, nanotechnology micro robots. The sprayed material spreads out to become very widely dispersed and sinks slowly to the ground. People have no option but to breath in this noxious mixture. An air sample should have zero particles of free aluminium but air samples have now been measured with more than thirteen thousand (13,000) particles of free aluminium per litre. Those particles are nano-sized and that size passes through a person's nasal passage membranes straight into the brain, causing the premature death of brain cells. Alzheimer's and other degenerative diseases are now four times greater than they used to be, with occurrences being seen in people in their fifties instead of their eighties. The excuse (and it is only an excuse) for this spraying is that it is to oppose global warming. There is no global warming. We are moving into an ice age period which will last more than fifty years. The real purpose of this spraying is to make people stupid and ill.

An ordinary "con" (condensation) trail is caused by the rapid cooling of water vapour and carbon dioxide to form ice crystals and those trails do not normally persist for more than one minute. Chemtrails persist for a very long time and spread out to form a new type of cloud.



One of these two planes is laying a chemtrail, guess which one. Perhaps a slightly later photograph might help?

Hint: the contrail fades away quickly while the chemtrail most certainly does not – after all, it is there to poison you so there is a great deal there than just carbon dioxide and exhaust gas. This is what a sky heavily sprayed with chemtrails looks like:

Is this poisoning just in one place – perhaps a restricted test area?

Los Angeles

Paris

Texas

Indiana

Vancouver

New York

Perhaps we are mistaken and these trails come from ordinary aircraft carrying passengers?

Well, actually, some ordinary commercial passenger flights have aluminium added to the fuel so that they also spray aluminium nano particles in their normal exhaust trail. A chemtrail disperses and hangs in the air for a long period of time while the heavy particles in it drop slowly towards the ground.

Please understand clearly that this is a deliberate attack on you personally. It is universal inoculation with poisons without your permission. It is also a covert operation as you have not been told about it and in passing, you are funding it if you pay tax (which you are forced to do as taxation is a protection racket which you can't opt out of). So, welcome to our present reality!

However, the good news is that you can do something about it. First of all, the radioactive particles in the air are not just from the chemtrails but also come from the (supposed) accidents at nuclear power stations such as Fukishima, and the highly likely future "accidents" at other nuclear power plants. You can reduce the effect of radioactive particles in your body by using a couple of chemical compounds twice per day. Those are:

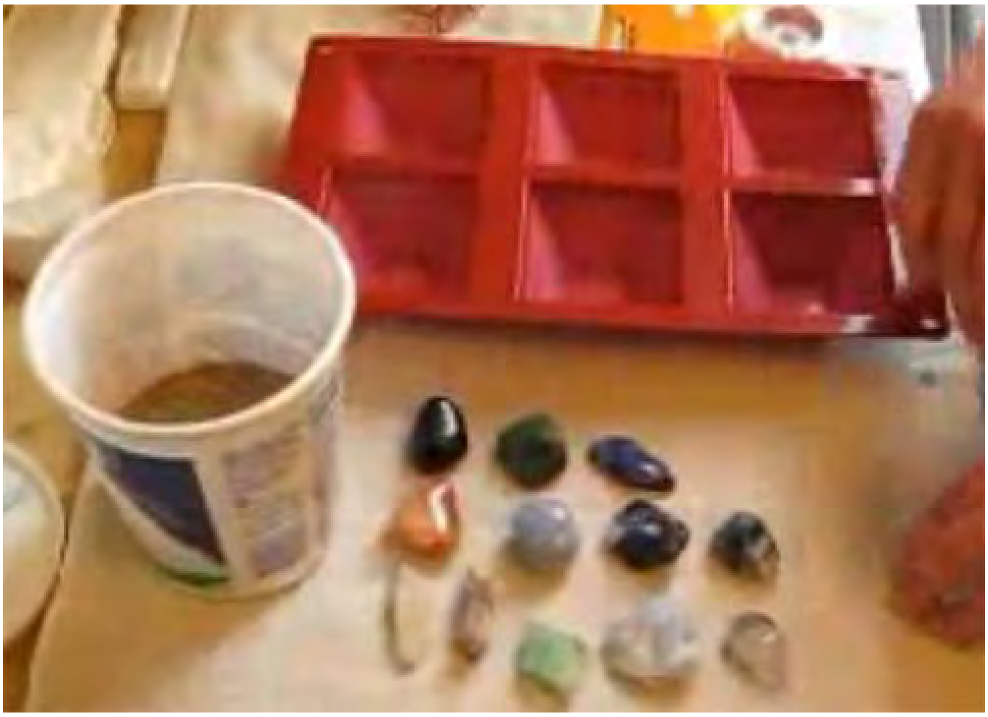
Tulsi tea which is also called Holy Basil and the herb Punarnava Mandur, both of which have been found to be highly helpful over many years of use.

However, we would really prefer to get rid of the chemtrail fallout before it reaches us and that can be done by using Orgone energy. Orgone is one of the many names given to the universal life force and it can be used to disperse and reputedly push the contaminants away from the earth.

It is worth watching the video at https://www.youtube.com/watch?v=YNfG5AYJxE0 where this matter is discussed in detail. The presentation is good and the home website of the presenter Sharon Daphna is located at www.thechembow.com where there is a detailed description of how to construct devices which can destroy chemtrails. This is one of many sites which provide instruction on the construction of such things, but it is very clear and straightforward. The objective is to construct a series of “orgonite” truncated pyramids as those can break up chemtrails by creating a vertical vortex of Orgone energy.

The things used for this construction are:
A flexible silicone mould to determine the shape and size of the finished device.
A potting compound to bind all the components, mixing cups, disposable gloves and stirring spatula.
One or more crystal - quartz, amethyst, malachite, calcite, or any such crystal.
A small helical, clockwise-wound coil of bare copper wire (which is **not** a ‘Tesla Coil’).
Small metal pieces such as brass, iron or copper (easily cut from multi-strand copper cable).
Crushed solenite (optional), and paper towels for general cleaning of spills, etc.



The pyramids are made in two separate sections. First, the potting compound is mixed. As the mixture gives off heat and fumes, this really needs to be done outdoors when the temperature of the day is 60F (18C) or more as the resin needs to be reasonably warm before being used. The resin is then poured into the moulds to fill them part way:

Next, small metal pieces are added - in this case, brass filings (obtained free from a locksmith):

An alternative here would be to use stranded copper wire and cut off very short lengths as each cut produces several short lengths of copper wire. In this construction, a small amount of iron filings is also added to give extra output power:

A coil is wound using any diameter of bare, solid copper wire. In this instance, the coils are wound around a pencil with the turns are spread out and only about 5 inches (125 mm) of wire is used per coil:

A different type of crystal is added to each of the pyramids and most interestingly, the crystals are laid flat instead of arranging a pointed end to be vertical:

Next, some more resin is added and the small copper coil is added in an upright position. Also, if the main crystal is not quartz, some extra small pieces of quartz are added to give extra operational power:

The construction is now left for an hour so that the resin can stiffen up without setting fully. Then some more resin is mixed and poured so that all of the components are covered. Then twenty-four hours are waited so that the resin is set fully, and then the pyramids are removed from the mould:

However, this type of pyramid is intended primarily for use around your home, while a more simple version called a “Tower Buster” is made in bulk to deal with wide areas of country. The ones shown above have cleared up the skies around Sharon’s house for a distance of about one mile in every direction, and so are very effective. The more simple version is less pretty but very effective. It is made with a cheaper resin and is made using an ordinary ‘muffin’ baking tray which is lubricated to stop the resin sticking to it:

These simple shapes of Orgone are very important. All around developed countries there are now cell phone towers. They vary a bit in their construction, but generally they look like this:

These innocent looking towers transmit both cell phone signals **and** other signals which are intentionally damaging to humans. It is very important to neutralise these towers and that can be done quite easily by placing an Orgonite Tower Buster anywhere within fifty metres of the tower. The Tower Buster can be buried to make it hard to find, but a Tower Buster will neutralise the harmful signals coming from the tower without preventing the cell phone signals from operating normally.

In other words, by adding a Tower Buster Orgone device to the area of the cell phone tower, you, personally, can improve the living conditions for everyone in your neighbourhood. Orgone enthusiasts also drive around the country, occasionally throwing an Orgone Tower Buster out of the car window so that it lands in bushes or trees. That is called “gifting” Orgone to the area and it clears major regions of chemtrails.

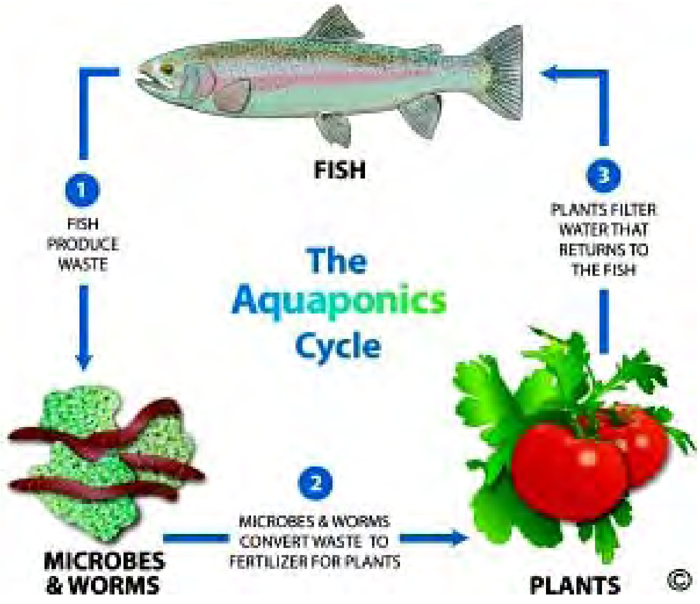
If, for some reason, it is not possible to make orgone pyramids or Tower Busters, then remember the Orgone treatments of chapter 23 where a plastic ring filled with Carbon GaNS water is used to promote the growth of vegetation by boosting Orgone flow where it is needed. Here, the ring is applied to the trunk of a tree:

But, there is no reason that I know of why a ring like that should not be used as a Tower Buster or as any other form of Orgone booster. For example, if it is necessary to sit in a chair all day, there is no reason why a GaNS water ring should not be placed around the chair so that the person sitting on the chair receives a boost of Orgone energy when sitting there.

For years, governments denied that they were spraying chemicals on the general population. Eventually, they admitted that they were undertaking “geoengineering” (which involves spraying toxic chemicals on the general population). Interestingly, the American company Monsanto was developing aluminium-tolerant plants during that time. Isn’t it a remarkable coincidence that one of the major chemicals being sprayed is free aluminium - the metal associated with degenerative diseases such as Alzheimer’s and Parkinson’s disease?

As the Earth is entering a period of global cooling which will form one of the many ice ages already experienced by humanity, the ridiculous excuse that aluminium is being sprayed to offset “global warming” is laughable and even more so when it is said that humans are responsible for global warming through the production of carbon dioxide. It is already known that carbon dioxide is not the main global warming gas as that is water droplets in the air. Also, global warming took place well in advance of the industrial revolution which is supposed to have caused it, not to mention the fact that humans come a very poor third in the amount of carbon dioxide produced on Earth, with volcanoes being the leader, and insects and animals coming second, leaving humans a long way behind. Nor is it mentioned that with the amounts of carbon dioxide already in the air, increases no longer have any great warming effect at all. It might be remarked on that carbon dioxide is not a poison. We breath it out and plants need it to grow.

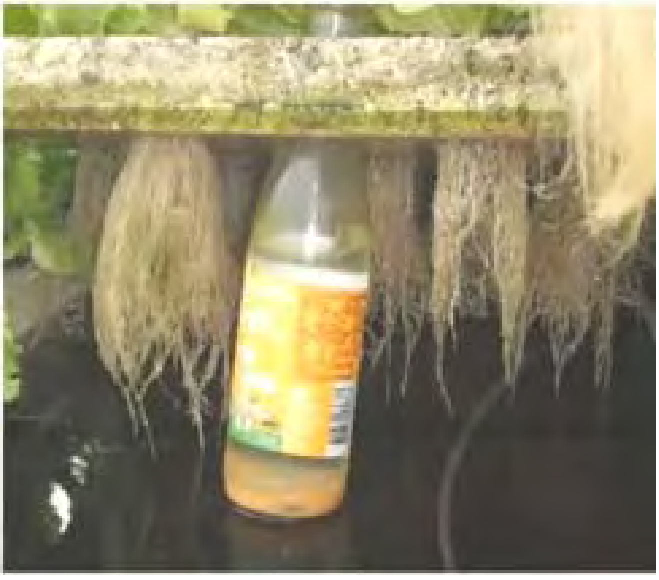
Anyway, if aluminium contaminated soil is a problem for farming, we may have to switch to using mainly aquaphonics where soil is not used and nutrients are fed to the plants through the water. Some versions of that use fish to complement the process in what turns out to be a very effective system:



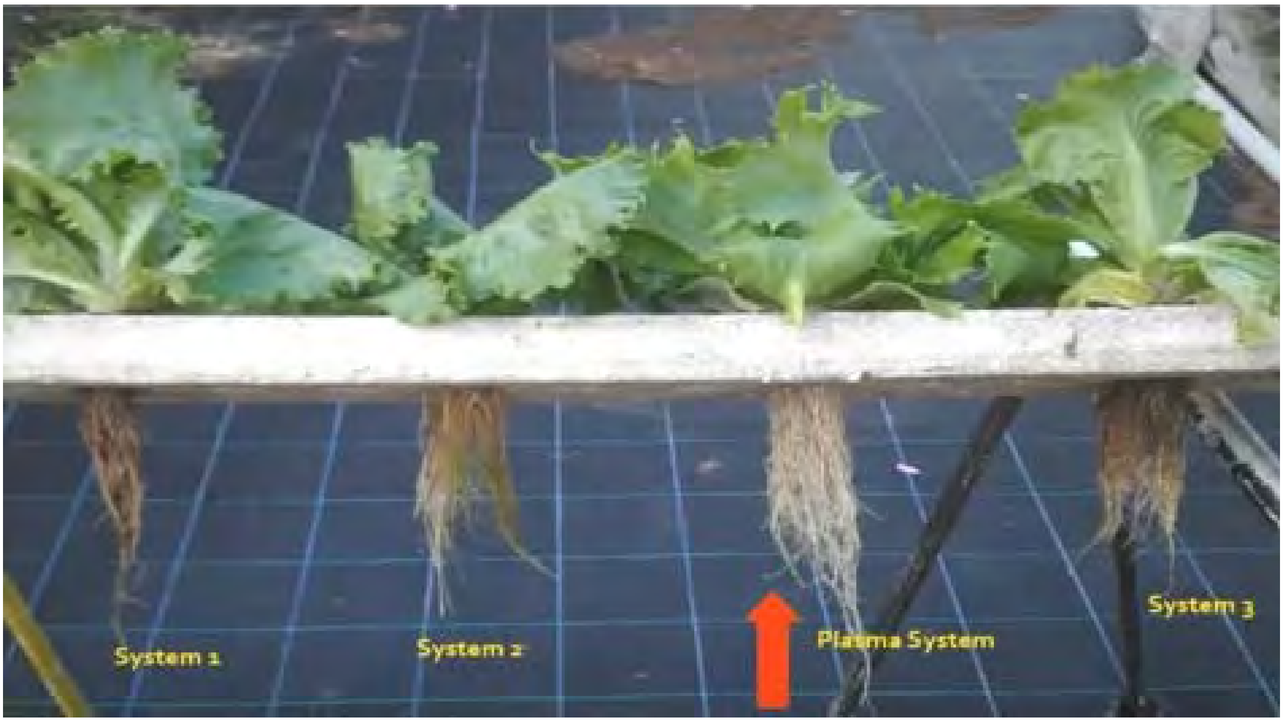
FISH
1
FISH PRODUCE WASTE
The Aquaponics Cycle
3
PLANTS FILTER WATER THAT RETURNS TO THE FISH
MICROBES & WORMS
2
MICROBES & WORMS CONVERT WASTE TO FERTILIZER FOR PLANTS
PLANTS
©

The most direct description for this is probably that fish live and breed in the water. While doing that they produce waste and microbes and worms break down that waste which then forms most of the nutrients needed by the plants. The plants absorb the nutrients and grow and in that process they clean up the water so that the fish have clean water in which to live. That is, of course, a very simplified description of what happens and there is a whole area of expertise involved in the successful running of an aquaphonics system.

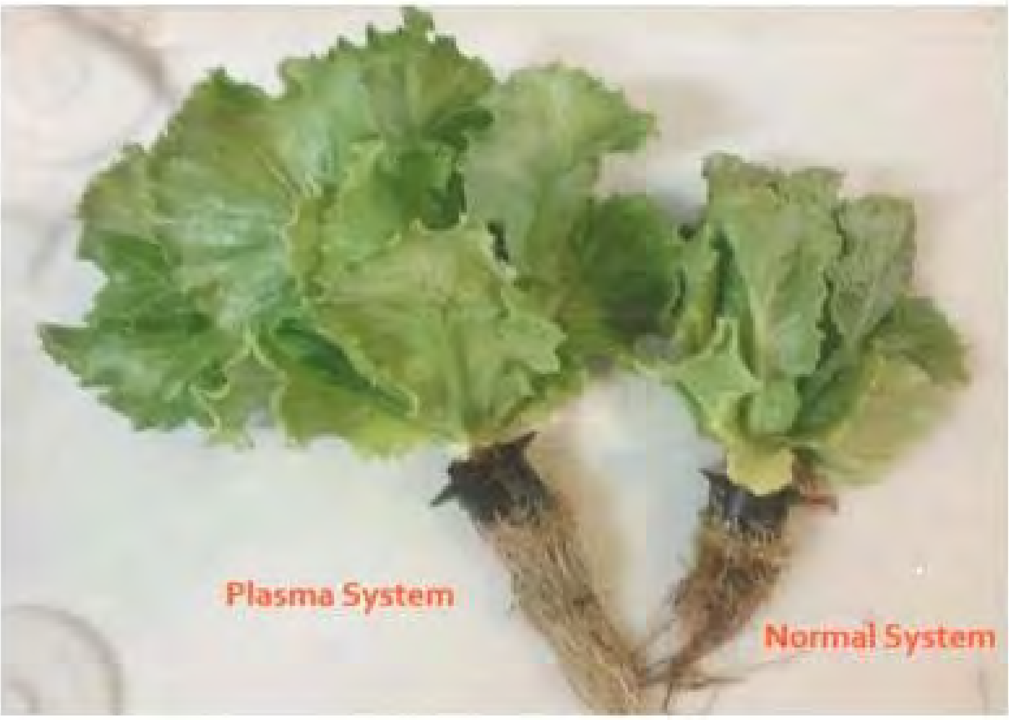
The aquaphonics system would need to have a cover to keep any extraneous contaminants being dumped into the atmosphere, and Orgone devices to boost the plants and fish in the system. We may soon be driven to using such systems courtesy of the present spraying of toxins by "the powers that be". A video on aquaphonics in very difficult temperatures can be seen at: https://www.youtube.com/watch?v=3LnG-ASYL1o&t=21s where the difficult conditions are eased by the use of GaNS material as described in chapter 23. The GaNS material is placed in a bottle which is then suspended in the water tank:



And that inclusion makes a massive amount of difference. Normally, using normal water, the hot weather causes premature shooting of the plants and it also causes weak, discoloured root systems and plants with thin leaves:



But, with the one 50 cc bottle of GaNS in the 24,000 litre water tank, produced much healthier plants with a normal white root system and a faster maturing time, not to mention the fact that the treated plants were typically three times heavier than the ones with just an ordinary water feed. Another detail is the fact that the fish were much more active and healthy with the GaNS system. After 31 days of growth, the difference in growth is very marked:



These 2 lettuce plants were seeded 3 days apart and grew in 2 separate systems. Represents an average plant size from each system.

Harvested after 31 days in system 20/3/16

With aluminium contaminated soil, this sort of growing system may become essential.

However, Clif High, who is a very able presenter on the internet, points out that the Sun is now moving through an area of the galaxy which is quite unlike any we have passed through before. In Roman times the Sun was predominantly yellow in colour but since the year 2000 or so, the Sun colour is now much whiter with a much higher level of damaging radiation. On the sixteenth of April 2017 Clif points out that chemtrails in USA are now four or five times higher than ever before and he assumes that this increase is directly related to the new radiation coming from the Sun.

I can confirm that there is a high level of chemtrail spraying in the UK at this time. However, that is an interesting theory from Clif, but if what he says is true, then there would not be the slightest reason for the people doing the spraying to lie about it. They would merely need to say that "due to changes in the radiation reaching Earth from the Sun makes it essential to spray chemtrails in order to offset the additional harmful radiation", but instead of saying that, they lie through their teeth and swear that they are not spraying chemtrails in spite of the fact that we can all see the chemtrails.

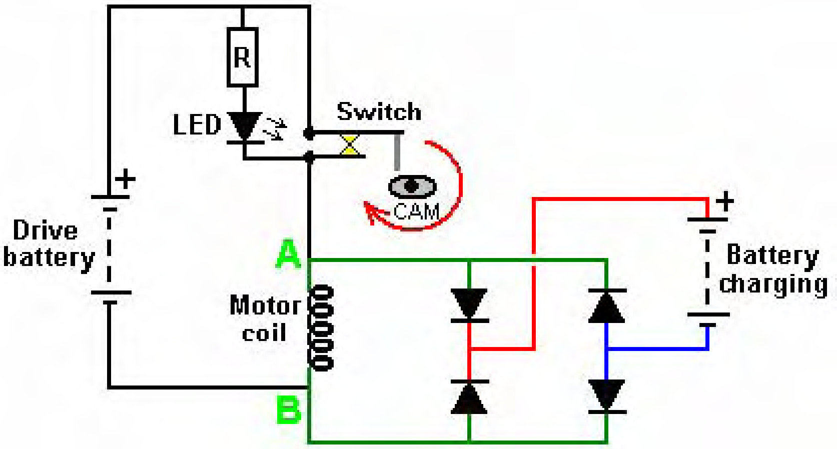
So, I leave it up to you to make up your own mind on whether or not the chemtrails are actually harmful and whether or not you should do something about them.

It has been indicated by various people that part of the attacks on humans is to be extreme weather events with excessive rain, droughts and the like. For that reason you should perhaps consider the following material:

David Wells has developed a small magnetic motor which he discovered has an effect on the weather. He has decided to place the design in the public domain so that it does not get lost or suppressed like a lot of other good ideas have been. Some of the information here comes from Alberto Feliciano who is experienced in building these motors.

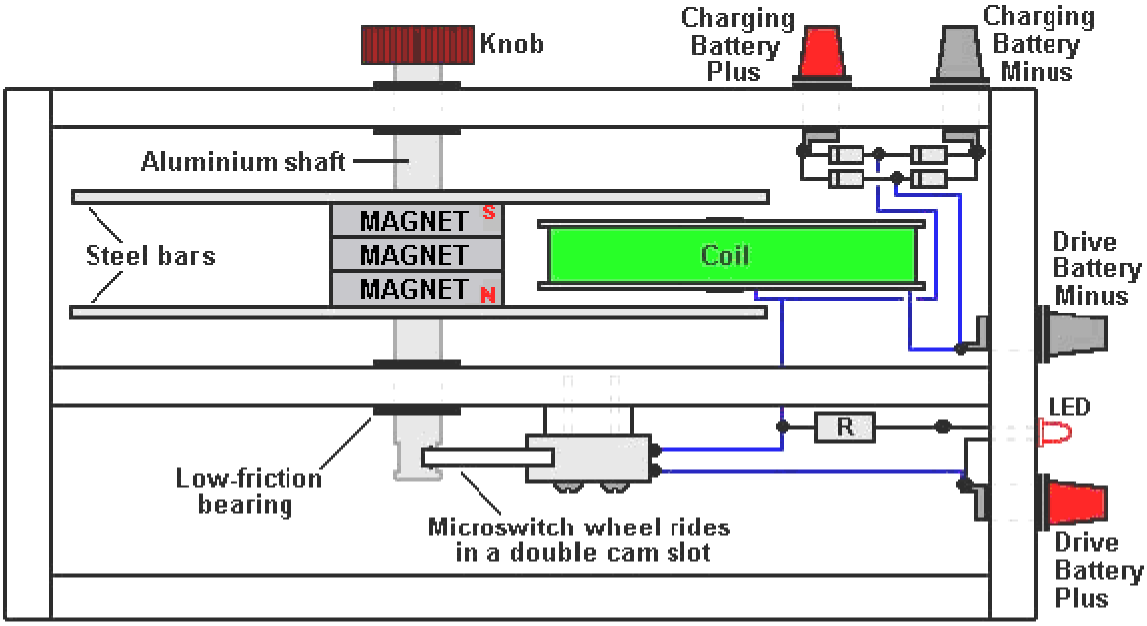
Building the Motor: David discovered the effect in 1994 when he built a small replication of Joe Newman's motor. When he attempted to determine what was going into the motor and what was coming out of the motor, he found that he could not make any sense of his oscilloscope readings. The commutator was creating too much drag, so he replaced it with car contact-breaker points operated via a small wheel rolling on a cam attached to the output shaft of the motor.

He then added a full-wave bridge rectifier and a second battery. This proved to be very satisfactory and no sparks were visible at the contact points. The drive battery would discharge and the battery under charge would charge up. The batteries could then be switched over and that kept the motor running for a long time. This is the electrical circuit:



The Current from the drive battery flows through the circuit, powering the coil which both stores energy and causes the motor shaft to rotate. Twice per revolution, the cam on the shaft of the motor pushes the switch contacts open, breaking the drive battery circuit. This causes the energy stored in the motor coil to expend itself in the form of a major voltage spike which pulls point "A" down to a long way below the point "B". This voltage spike is used to charge the second battery and the diodes need to be able to handle high voltages, say one thousand volts. If the drive battery has a voltage more than 1.3 volts greater than the charging battery, then the drive battery will also feed current into the charging battery when the switch contacts are closed. The LED performs the additional task of preventing the voltage spike from reaching the drive battery when the switch contacts open and this also suppresses the generation of radio-frequency radiation.

The motor is not a standard design. In broad outline, a single rotor is caused to spin by pulses applied to the coil:

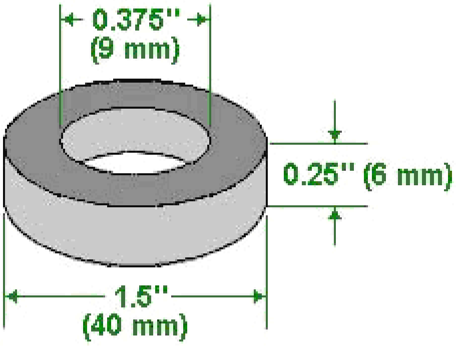


Knob
Charging Battery Plus
Charging Battery Minus
Aluminium shaft
Steel bars
MAGNET
MAGNET
MAGNET
S
N
Coil
Drive Battery Minus
LED
R
Drive Battery Plus
Low-friction bearing
Microswitch wheel rides in a double cam slot

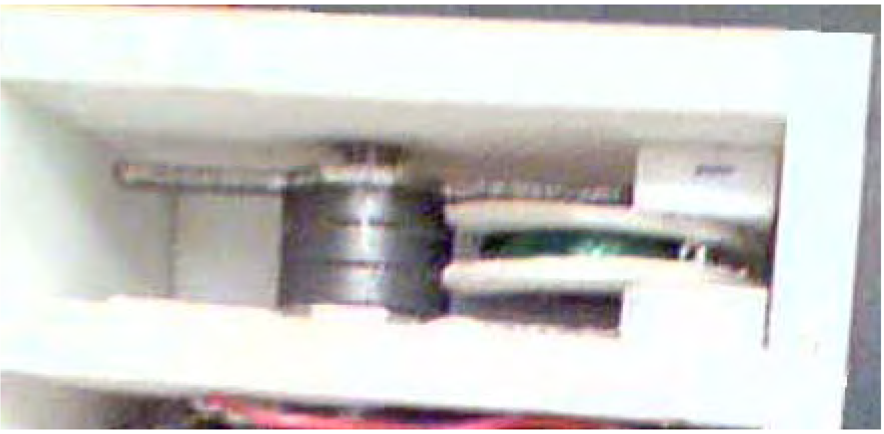
In the version shown in the diagram above, three toroidal (ring-shaped) magnets are stacked together around a central shaft. These dimensions are not in any way critical and magnets up to four inches (100 mm) in diameter have been used very successfully. Mounted on each side of these magnets is a strip of mild steel 1.25” (32 mm) wide and 0.25” (6 mm) thick. The shaft has a knob mounted on it to allow the rotor to be given a spin to get it going. The shaft has two flat faces filed into it and these make that section of the shaft act as a double cam which pushes the shaft of a switching device. The diagram shows a roller micro-switch but the switch of choice for David is contact breaker points from a car ignition system, modified to be pushed by an arm with a roller mounted on the end of it.

The box is constructed from any non-magnetic material such as food-chopping board plastic, timber, plywood, etc. and the box can be left open at the top. Using thick timber causes the motor to run very quietly. None of the dimensions are critical. The internal partition and the side containing the bearing are clamped together in exact alignment and the (push-fit) holes for the ball bearings are drilled exactly square-on using a pillar drill to ensures that there is perfect alignment when assembled:

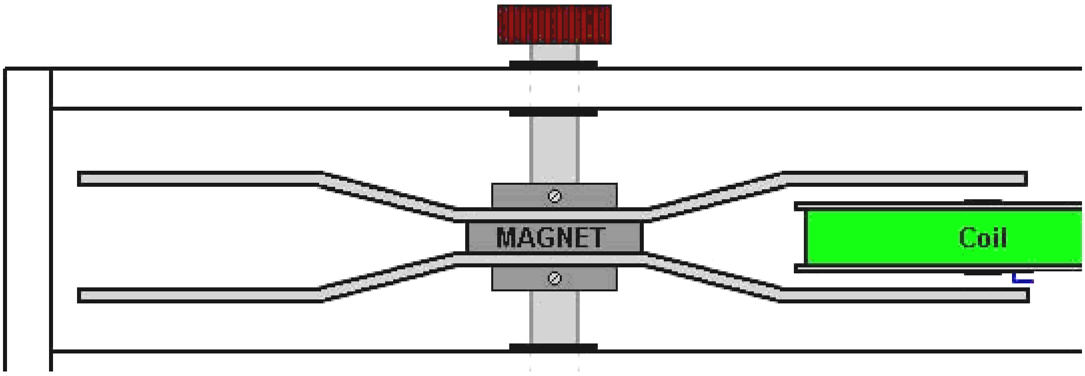
The ring magnet dimensions are not critical in any way. The first ones used had an outer diameter of one and a quarter inches, were a quarter of an inch thick and had a three-eighth inch hole:



These were stacked three deep:

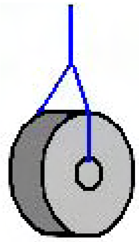


It is not necessary to use more than one magnet but if only one magnet is used, then it is usually necessary to bend the steel strips in order to clear the coil which is about one inch (25 mm) thick at it's widest point:



The steel strip needs to be longer to allow room for the bent sections and this in turn means that the box needs to be somewhat wider. The gap between the coil core and the steel strip is anything from 1/8" to 1/4" (3 mm to 6 mm) and that makes the gap between the steel strips about 1.5" (35 mm). Even though there is a strong grip between the steel bar and the magnet, it is necessary to glue them together along the edges using superglue or some other powerful adhesive. This is to make sure that the two steel strips are always aligned with each other. Being made of magnetic material, both strips take up the magnetic polarity of the magnet face to which they are attached. When they spin around, it produces a rotating magnetic field and it is well known that a rotating magnetic field interfaces to the local environment. In this instance the magnetic field is very weak and so the effect is limited.

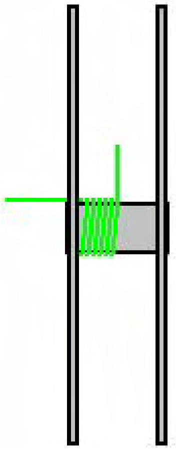
The way that the coil is wound and the orientation of the magnet(s) is important. initially, we will cover the steps needed for building with a single magnet and then explain what needs to be done when more than one magnet is used. First, establish which face of the magnet is it's North pole. This is done by hanging the magnet up using a piece of thread as that allows the magnet to rotate without any great turning force from the thread:



The magnet will eventually settle down in one position. One of it's faces will be facing magnetic North and that face is the **North** pole of the magnet as that is the face which is attracted to the Earth's North magnetic pole. If you don't know which direction is North, then if you face where the Sun rises in the morning, the North will be on your left hand side. Mark the North-seeking face of the magnet with an "N".

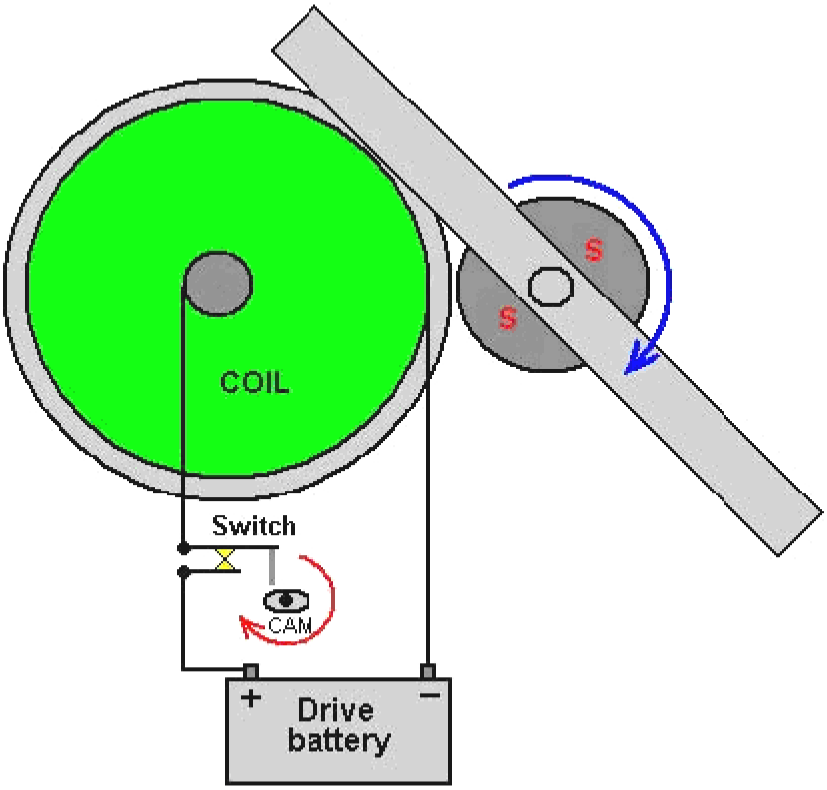
The coil is now wound. The central core of the coil is recommended to be iron, half an inch (12 mm) in diameter and about one inch (25 mm) long. Iron is chosen because it magnetises easily but does not retain it's magnetism, and so it is a good material for making an electromagnet, which is what our coil is. It can be quite difficult to get iron nowadays as steel is so popular. However, as steel does not lose it's magnetism, it is not suitable for our coil core. One very good alternative is the bolt from a masonry anchor, as it has the same magnetic characteristics as iron, is widely available from building supply outlets, not likely to go obsolete and it does not rust:

A coil spool is then constructed with a central hole (which is a tight fit for the short metal core) and flanges which are about 3 inches (75 mm) in diameter. The wire used to wind the coil is not at all critical, but it should weigh about one pound (450 grams) and it can be enamelled copper wire, plastic covered or varnished wire. The whole of a standard 500 gram reel of enamelled copper wire could be used. The direction of the coil turns is important and winding should be as shown here:



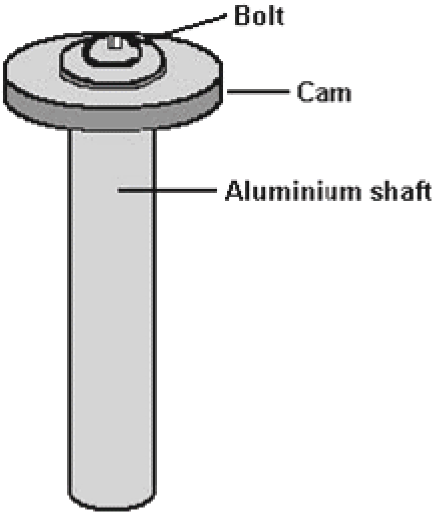
While this diagram shows gaps between the turns, this is only to make it easier to see the direction of the winding and the actual winding has each turn touching the turns on each side of it. The number of turns depends on the thickness of the wire. The thinner the wire, the greater the number of turns, and the lower the drive current will be. The turns are made from the left hand side of the bobbin to the right hand side and back again until all of the wire has been wound. David feels that it is important that the final turn should exit the bobbin 180 degrees away from the start of the first turn. I am not aware of any factor which would form the slightest basis for this, but then again, there is no particular reason why this should not be done.

One suggested wire size is American Wire Gauge No 22 which is the UK Standard Wire Gauge No. 23, with a wire diameter of 0.7 mm. A 500 gram reel of 22 swg wire contains 140 metres of wire which has an overall DC resistance of 7.5 ohms. However, as the coil is pulsed rather than fed a continuous current, the AC impedance of the coil is far more important, and that depends on the coil shape, core material and the number of turns in the coil. The way that the coil is wired up is important and it should be as shown here:

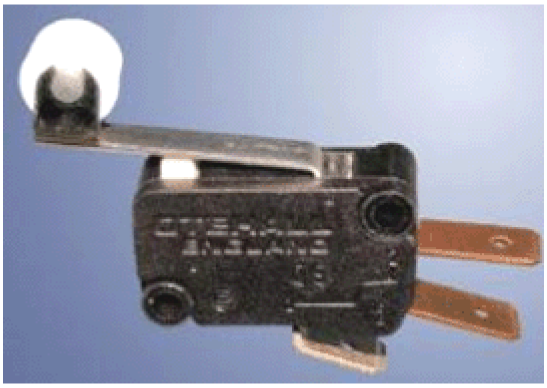


The diagram above only shows the direct coil connections and the additional LED and rectification components including the battery on charge, are not shown. The cam switching is arranged so that the current to the coil is applied when the steel strip is vertical and then cut off again just as the steel strip reaches the core of the coil, this makes the steel strip operate in the magnetic attraction mode which keeps it spinning, at about 500 rpm for the build shown above.

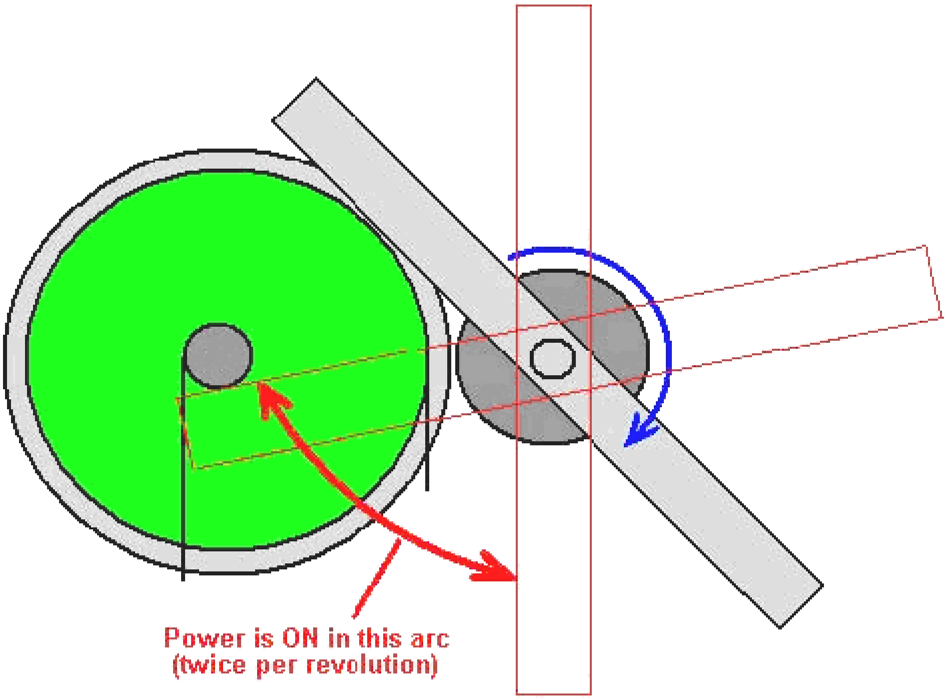
There are various ways of achieving the switching. You can make a cam out of almost any rigid material and attach it to the aluminium shaft by drilling a slightly under-sized hole in the end of the shaft and screwing a standard small bolt into the soft aluminium:



Bolt
Cam
Aluminium shaft



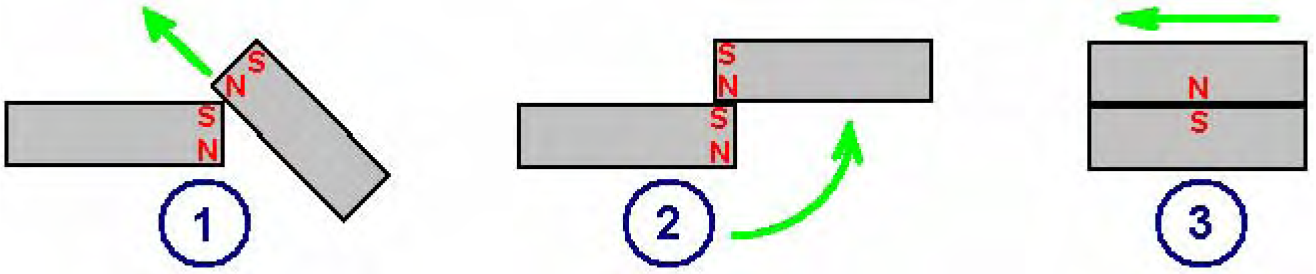
A standard micro switch as shown above can be used to do the switching with the switch mounted so that it’s roller runs along the face of the cam. While micro switches operate with tiny forces, if you feel that there might be undue friction at the bearing of the roller, then a flat arm version of the switch can be used, either with a straight lever or with a shaped lever:



Power is ON in this arc
(twice per revolution)

David believes that mechanical switching causes a sharper break in the current than using semiconductors for controlling the power supplied to the coil and a fast switch-off appears to be important in this application. The cam itself should be separate from the shaft and attached to it with a screw or bolt which can be loosened to allow the angle to be easily adjusted. It is very important for weather control that the switch-off occurs just as the leading edge of the steel strip reaches the edge of the coil's core. Some experimentation will be needed to find the cam shape which switches on and off at the correct positions of the steel strip.

As it is more convenient not to have to bend the steel strips, using more than one magnet is a popular idea. This requires some care. Firstly, these magnets can be very powerful and because magnetic forces can't be seen, it is not unusual for people to get caught by the surprisingly large attraction between two magnets or between a magnet and a piece of magnetic metal. Fingers can easily be injured even if care is taken, so wear strong "rigger" style gloves and when putting two magnets together do it at an angle and when the magnets touch, slide them into the required position and do **not** bring them together square on:



Even with the technique shown here, this is an opportunity for you to show off your muscle strength because the forces involved are very high when strong magnets are involved, so be careful. Step 1 is to bring the magnet in at an angle so that the two North poles push apart and oppose the pull between the incoming North pole and the stationary South pole. This reduces the devastating attraction very considerably. The movement needs to be slow as it is easy to damage one or both of the magnets if they are allowed to touch at speed, and they are capable of accelerating very fast once they get close to each other.

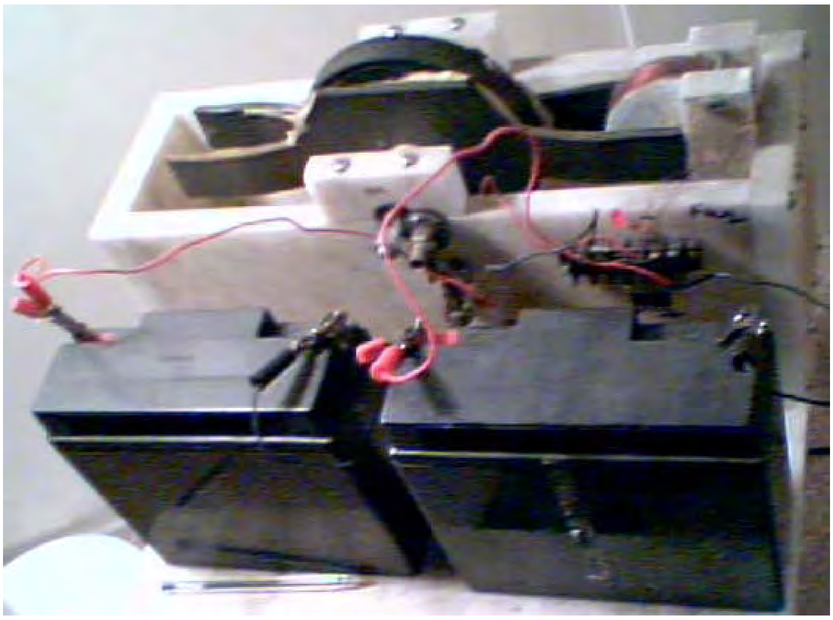
The step 2 position has the North-South attraction greatly reduced as only a tiny percentage of each magnet is involved in the pull towards each other. Also, there is a level effect to help you control the movement.

Finally, the incoming magnet is slid carefully into full contact with the stationary magnet and as the direct pull of the magnets is not involved in this movement, it is not too difficult to manage safely.

That is just the physical method of getting two strong magnets together without damaging yourself or the magnets. It does not deal with how the magnets are positioned relative to each other. In practice, magnets can have many separate poles on different faces. This is something which tends not to be noticed as most applications will work well with a wide range of different multiple-pole configurations. However, in this application, we want the optimum arrangement if we use more than one magnet.

To assess the magnets accurately, identify the magnetic poles as already described. Then, place a magnet face down in a plastic bowl and float the bowl in a container of water. This provides a very low-friction bearing which allows the magnet to rotate freely in a horizontal direction. In theory, the magnet should have no inclination to take up any particular orientation, and if that is the case, then that is very good. In practice, it is quite likely that given time, the magnet will rotate and take up a definite East-West orientation. If this happens, mark the side which points East. Repeat this for all of the magnets to be used, and when putting them together to form a stack, make sure that all of the "East" marks are exactly above each other. That gives the best possible magnetic stack which can be made from those magnets.

There are, of course, many different ways to construct this type of motor, and this is an example of one of them where the bearing alignment is achieved without drilling but by clamping directly on top of the edge of the housing with only part of the locking nut and washer gripping the top edge of the box as shown here:



In this example, a twelve-volt battery is used to drive the motor and a second twelve-volt battery is used to absorb the voltage spike produced, which incidentally, charges the battery and consequently, the batteries can be swapped over from time to time. This arrangement is nearly 100% efficient.

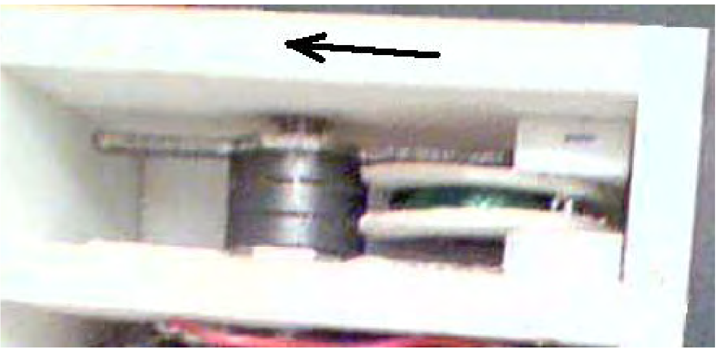
It is not necessary to run off twelve volts and it has been found quite satisfactory to use a small 3-volt mains unit to drive the device, especially with a coil wound from fairly fine wire (which requires less current to run it) and in that instance, the charging battery was replaced with a resistor whose job was solely to soak up some of the voltage spike and ease the load on the switch.

The value of the resistor used to limit the current through the LED depends on the voltage used and if a current of about 10 milliamps were required, then a 820 ohm resistor for a twelve-volt system or a 330 ohm for a three-volt supply would be expected. However, David says that a resistor of about 3K ohms should be used. Using a 2.7K resistor would give an LED current of about 4 milliamps during the two-thirds of each revolution when the LED is not being short-circuited by the switch. The light coming from the LED is not going to be bright at that current level, but the inclusion of the LED is due to it's effect on the circuit and not for producing light.

David suggests using a diode bridge rated at 400 volts and 6 amps. This is possible but I would suggest using four separate diodes such as the 1N4007 or the 1N5408 both of which are rated at 1,000 volts and higher current and which are very cheap because they are so popular. Wiring them as shown in the physical layout diagram gives a very neat arrangement. The terminals shown are the type which allow wire attachment with plugs or a screw-down clamp on a (clockwise wound) turn of bare wire. These terminal posts, the diodes, resistor and LED can be got from any electronic components supplier. A supplier local to you can be found with a Google search.

Using the Motor: This design of motor has not been used for weather modification for a long time and so there are no definitive rules on its use at this time. The effects vary from place to place, probably due to the differences in the local environment.

It is normal to mark on the box, the direction in which the motor "points". This is determined by considering the magnet as being a wheel rolling down a road, and the direction of travel is considered to be the direction in which the motor is "pointing" and that is then marked with an arrow:



The motor can be operated with this arrow pointing in any direction. However, it is usual for it to be pointed North or any direction in 45 degree steps away from that, i.e. North-East, East, South-East, South, etc.

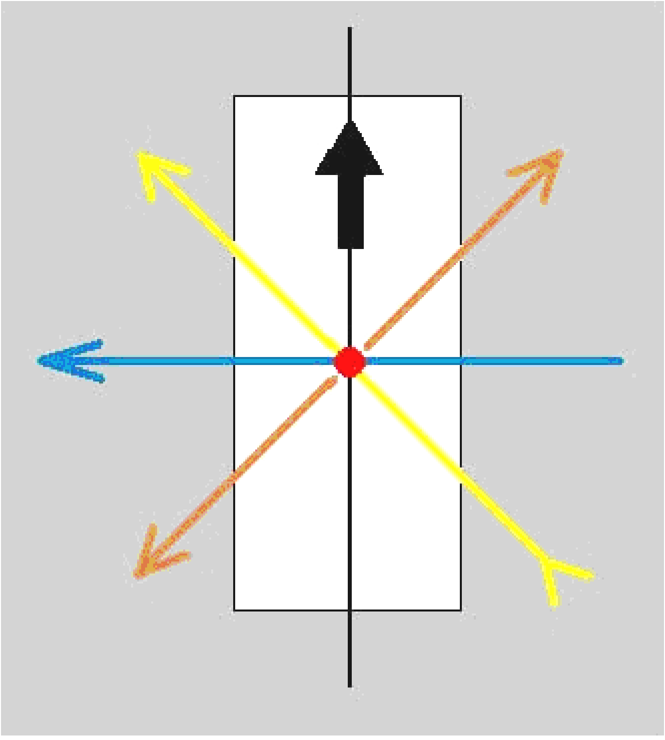
Experimentation is needed to see what (if any) effect is produced in your locality by the motor. In David's location, when the motor is pointed East it clears away the cloud cover. This usually happens in three to ten minutes. Turning the motor to face in the opposite direction brings the clouds back and causes rain but this takes much longer than clearing the clouds away, typically about half an hour. Please remember that the direction is highly dependent on location. In the New Mexico area of America, the reverse is true as pointing East causes rain and pointing West clears the skies. The machine loses power during new and full moons, but that can be corrected by raising the input voltage.

Alberto's experiences: Aiming the machine to tame a hurricane is not difficult. It is important that we do not leave the machine running in the same direction endlessly, This is a brand new science and it not yet known if these low-powered machines have long-distance effects (I believe that they do but this has not yet been proved).

It is my experience that pointing the machine towards the incoming, high-altitude winds, will stop the rain. High altitude wind directions and ground level winds are almost always different, so don't go by your local weather forecast of the wind direction. The best way to find out which way the high winds are moving is by looking at a satellite image. The web site at http://www.intellicast.com/Global/Satellite/Infrared.aspx?location=PLXX0055 shows the wind patterns anywhere in the world and clicking on any map location gives an expanded view of that area.

Note: When the wind is described as "North-Easterly" that means that it is originating in the North East and blowing from that direction towards the South West.

This "Colour Arrows" diagram can be printed and placed on your machine:



The operation of this machine is not just one simple push in one direction against the weather. The machine has several effects simultaneously. The black arrow in the diagram indicates the direction in which the machine “runs”, that is, if the magnet were a wheel resting on the ground, it is the direction that the magnet would move.

The Yellow Arrow: the machine generates effects in several directions. The most important one is in the direction of the yellow arrow (45 degrees to the left of the running direction of the machine). The effect causes both a push away from the machine in the direction of the yellow arrowhead and at the same time, a pull in towards the machine, also causing movement in that same direction.

I (Alberto) am located in the tropics. If I pull from the North, I will be making rain (floods if I am not careful), because the masses of air to the North of my latitude are colder. The prevailing winds (these are seasonal winds that blow predominantly from a single general direction over a particular area in the Earth's atmosphere) will combine with the machine's force and will steer the mass of cold air to your right or left, depending on the wind direction. So, when pulling, we need to take the high altitude wind direction into account so that the mass of cold air doesn't miss us when it gets here. One of my favourite ways of making rain is by bringing together a mass of hot air and cold air. If it's hot in the country, then pull in a cold front. When the cold front I have been pulling arrives the warm air already here has it’s temperature lowered which causes it to release it's moisture, and we get rain. Warm air always holds more moisture than cold air and when they meet, the warm air releases it's moisture. You must understand that this process takes time, about two or three days because we are dealing with the relatively slow movement of large masses of air.

If it is cool in your country, you can pull warm air in from the South at an angle to the prevailing winds and that should create the same effect. It can't be done directly, though... you have to do it using vectors. When we are pulling the cold front towards us it keeps on moving in it's original direction as well, and it's natural tendency will be to continue on that path. So we aim the box to pull the edge of the cold front so that we attract it and change it's course enough that it may pass over us when it arrives into our general area. I have done this by yellow arrow pulling for a few days on the outer edges of the cold front I needed to attract, adjusting the aim occasionally to bring it down closer each time, compensating for the cold front's movement. It worked very well and produced much rain.

This is a touchy subject. If we push or pull too much, it will create flooding. No more than a few hours of force should be applied at a time in the beginning, at least until you get familiarised with what your machine can do. You will be pleasantly surprised when you discover the effects which it can create.
If we apply a Yellow push towards a cloud, it will more than likely disappear. The same happens with a

Yellow pull. Cloudbusters work the same way and if we point one of them directly at a cloud it makes it dissipate. I have noticed that when I am running the machine North-West for any extended period of time, a column of clouds will form running alongside the Yellow arrow line about 800 miles to the left of my location. When you run your machine you affect the weather in many places at once, so please go easy with your machine as nobody likes floods.

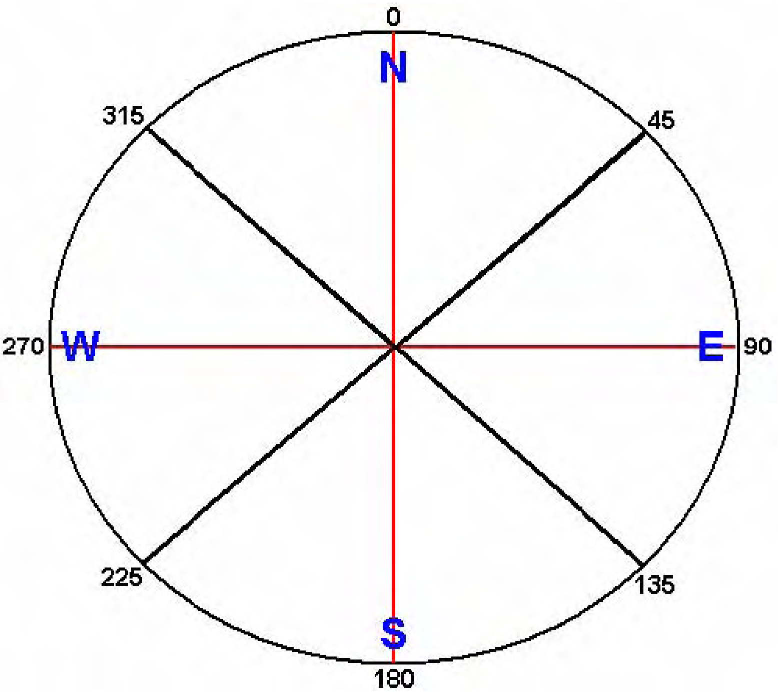
The time of day can help or hinder your attempts in rain-making. For a while I had some success aiming toward the Texas drought area, running 30 mins at nightfall and then again 30 mins the next morning at sun-up (until the seasonal high-winds changed). I created some nice thundershowers there the next day. We have also had success making rain when running two machines against each other, one in the North and the other 2,000 miles South, running “yellow push” against each other. It made really nice rain in a large area between the two machines after about 36 hours.

The Other Arrows: I have observed that there are four lines of force, not just the black and the yellow. You will see the Blue and Orange lines of force at work when you begin playing with the clouds above you, moving them this way and that. Don't be surprised if no one believes that it is you who's doing it. The clouds seem to like to group in some of the divisions more than others when you point with the Yellow arrow into the high altitude incoming wind. You'll see. The Orange line keeps me wondering because it seems to depend on how the others react to the direction of the wind. It will work one way when you move the machine in one direction and in another way when you again move the machine. It seems to act as some kind of magnetic boundary. In 2009, hurricane ‘Bill’ came by during a new moon (the machine loses power during new and full moons, but that can be corrected by raising the input power by a couple of volts, it can also be boosted by having a quantity of aluminium nearby). This was before we knew about the Yellow line and before the machine was modified for higher power. The hurricane escaped being dissipated but it got pushed out to sea where it couldn't do any damage. Since then, I simply don't let those systems develop into hurricanes any more because I can reach them from thousands of miles away. If I want to get rid of a hurricane I apply a Yellow push towards it remembering to adjust the aiming every few hours because of the storm's movement. If I'm trying to destroy a hurricane, then one or more hours at a time, but it really depends on how far away the storm is from me. Some storms and hurricanes which are about 3,000 miles away begin showing signs of being affected by my machine in about 3 hours and have taken about 7 more hours after that to dissipate. I always have to do follow-up work the next day on that same location because the storm will always try to get started again. After that it's gone for good. Tropical storms Ana, Erika, Nora and Patricia were eliminated by my machine. It also considerably weakened hurricane Rick in only a few hours from 185 mph (300 kph) to 65 mph (105 kph) before it made landfall. All of these occurred in 2009. We rely on internet satellite images to verify our work. The images are delayed by anything from 15 to 45 minutes, so you really can't see the effects of what you are doing until about an hour later. I almost always see exactly what I expect when the images are displayed.

Aiming: Now that you have read the basics we can get back to aiming the machine. Aiming will never be perfect, at least not with these first-generation weather machines which we are using, but it will be close enough to get the desired results. Up to now I have used only the Yellow arrow to affect the weather. This may change as we learn more about how the machine operates. Let's get ready to aim the machine. There are various ways of doing this, and the following is just one of those ways:

a. Mount your machine and it’s batteries on a movable board, or even better, a large plastic lid. This allows you to turn the whole thing around without having to alter the wiring. The edge of the machine should align exactly with the edge of the board so that we can use the edge of the board or lid to aim the machine.

b. Using a protractor, draw a complete circle with a diameter of about eight inches and mark it like this:



and while this diagram only shows angles marked every 45 degrees, you mark yours off with additional ticks at 5 degree intervals. This diagram is then ready to be taped to the table or floor where you normally keep the machine.

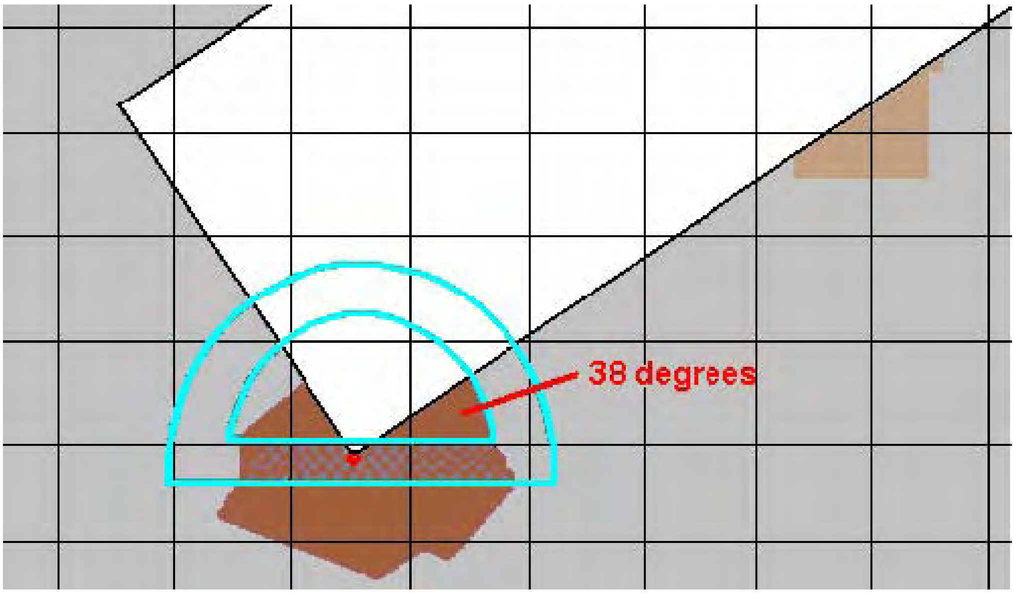
c. Use a compass to find magnetic North. Do this from several places in the room and remember that the machine's magnet and any other magnet or large metal object will interfere with the reading. Use something on a wall of the room, or alternatively, a tree outside to use as a sighting line for magnetic North and line up your protractor diagram very accurately so that the 0 degrees (North) line is aimed directly towards magnetic North.

d. Decide whether you are going to push or pull when using the Yellow arrow and make a note of your choice.

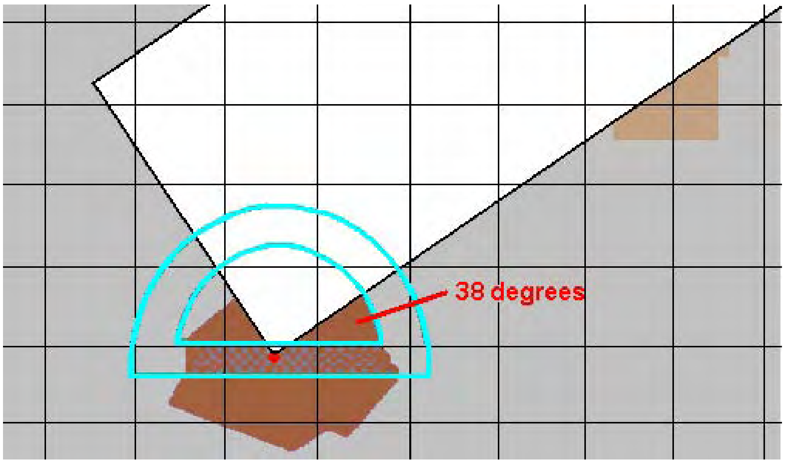
e. If you live in a hurricane area of America, keep your WeatherRadio with you throughout the day. These radios are normally kept on standby mode and will be silent until a special alert emergency signal is transmitted from the National Weather Service. A timely warning could help you save lives, and one of those might even be your own.

f. Log your computer in to the weather map web site mentioned above. It is important that we have an appropriate map on the screen. That means a map where the latitude and longitudinal lines are straight and not rounded following the curvature of the Earth. We need a flat kind of map, not a rounded one. If a rounded map is used for aiming we will never hit our target. Once we have the right map on our PC screen, we bring desired area to a comfortable size so that both our location and the target are visible.

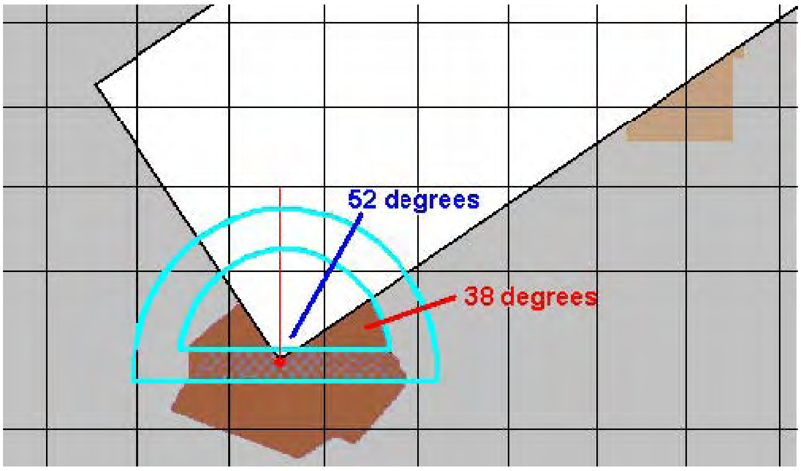
g. We place one of the corners of an envelope on our home and line the edge up with the target weather system.



h. We place the protractor centre, (the hole on the bottom part), on top of the corner of the envelope, line up the protractor with the grids on the map so that it is level with pointing north on the map and read the angle between our location and the target and write the angle down.

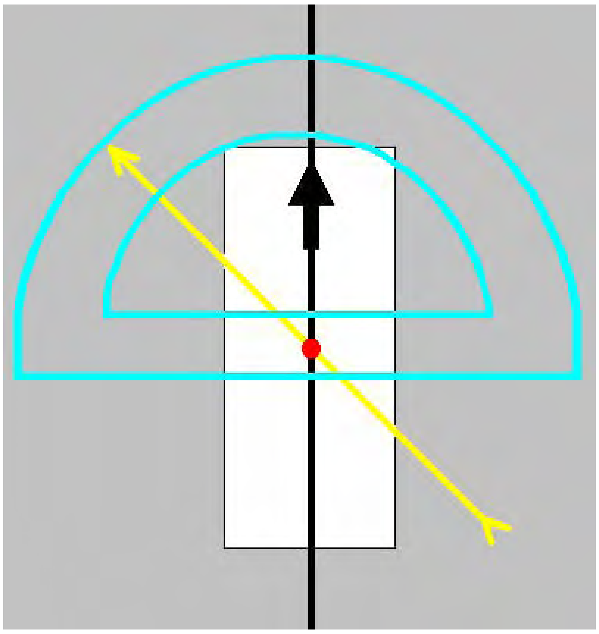


For example, let’s say that the angle is 38 degrees as shown above, and we want to push that weather system away with the Yellow line of our machine. One way to work out how to position the machine in order to do this is a matter of common sense. This method uses simple addition and subtraction to determine the angle to use – it is not a difficult thing to do. The angle between the line to our target and the direction to North is 90 degrees minus our measured 38 degrees. This is 52 degrees. In other words, the line to our target is 52 degrees to the right of North:

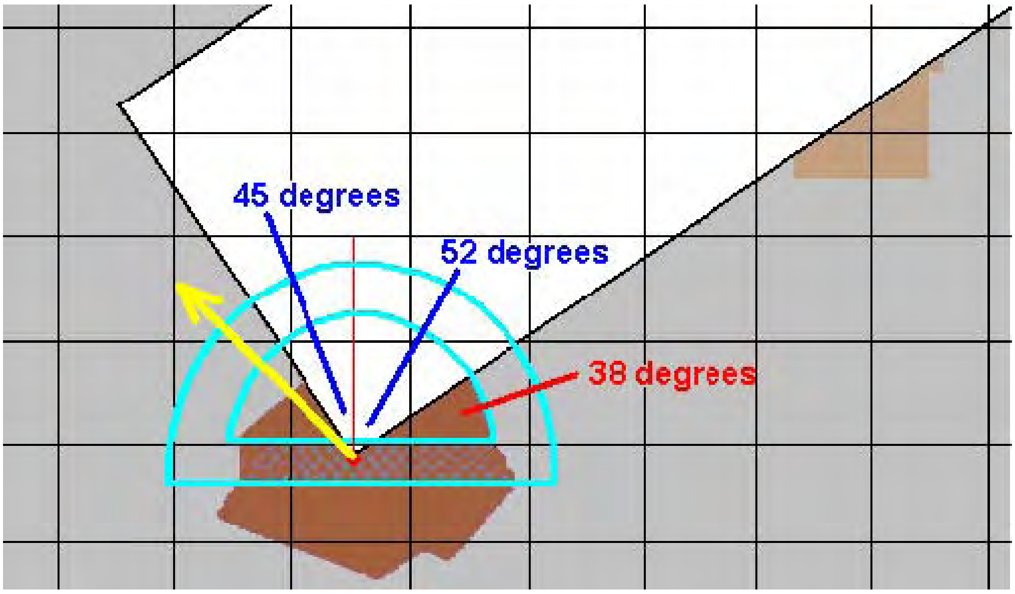


52 degrees
38 degrees

Remember how the Yellow arrow is positioned to the main North – South axis of the machine:

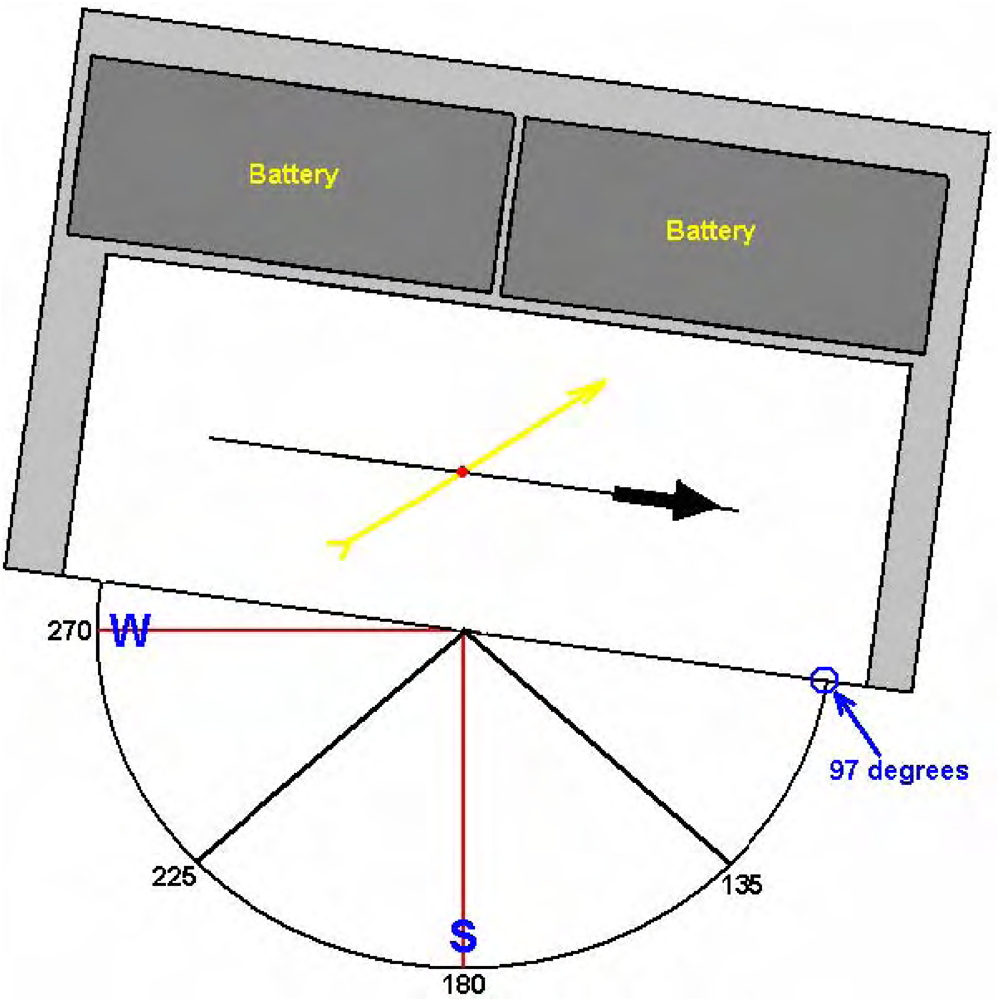


The Yellow arrow points 45 degrees to the left of the North – South line. So it is 45 degrees further away from our target than the North is:



45 degrees
52 degrees
38 degrees

i. So, to aim the Yellow arrow directly at our target, we need to turn the machine round to the right. If we turned it round 45 degrees to the right, the Yellow arrow would be pointing due North. But we want it to point a further 52 degrees to the right, so we need to turn it through 45 plus 52 degrees and that is 97 degrees. As the edge of the machine is pointing directly North before we move it, it too needs to swing round through this same amount of 97 degrees, and so, when correctly positioned, it will look like this:

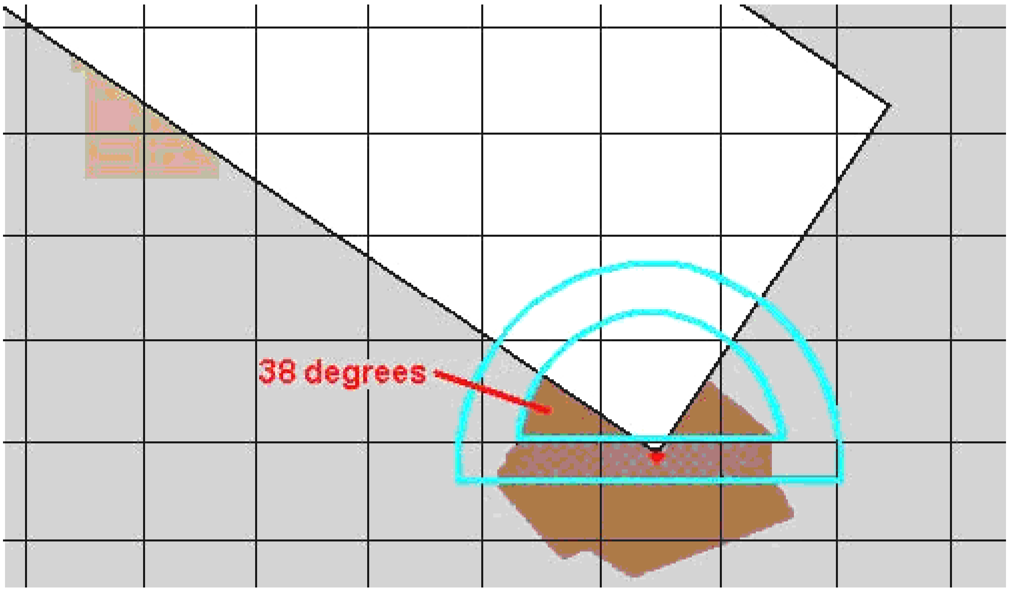


If we had set the edge of our board directly on the East – West line, then the Yellow arrow would be pointing up to the right at 45 degrees. But we have turned the board round to the right by a further seven degrees, lowering the direction of the Yellow arrow by a further seven degrees to the 38 degrees which we measured with our protractor and envelope. The machine is now set exactly where we wanted it to point.

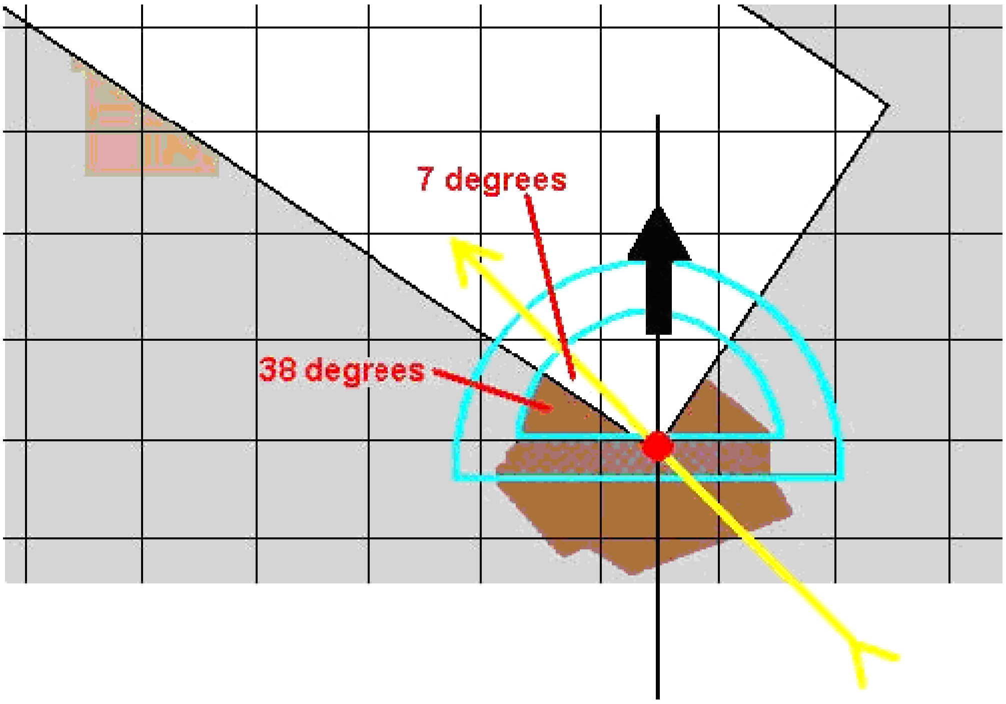
j. Start the machine operating, start a timer and write your notes: Date, Time of day, Target, Reason for running, Time that you started running, High altitude wind direction, etc. Watch the sky and the satellite images on your computer and enjoy the show.

k. Turn off the machine when done, please.

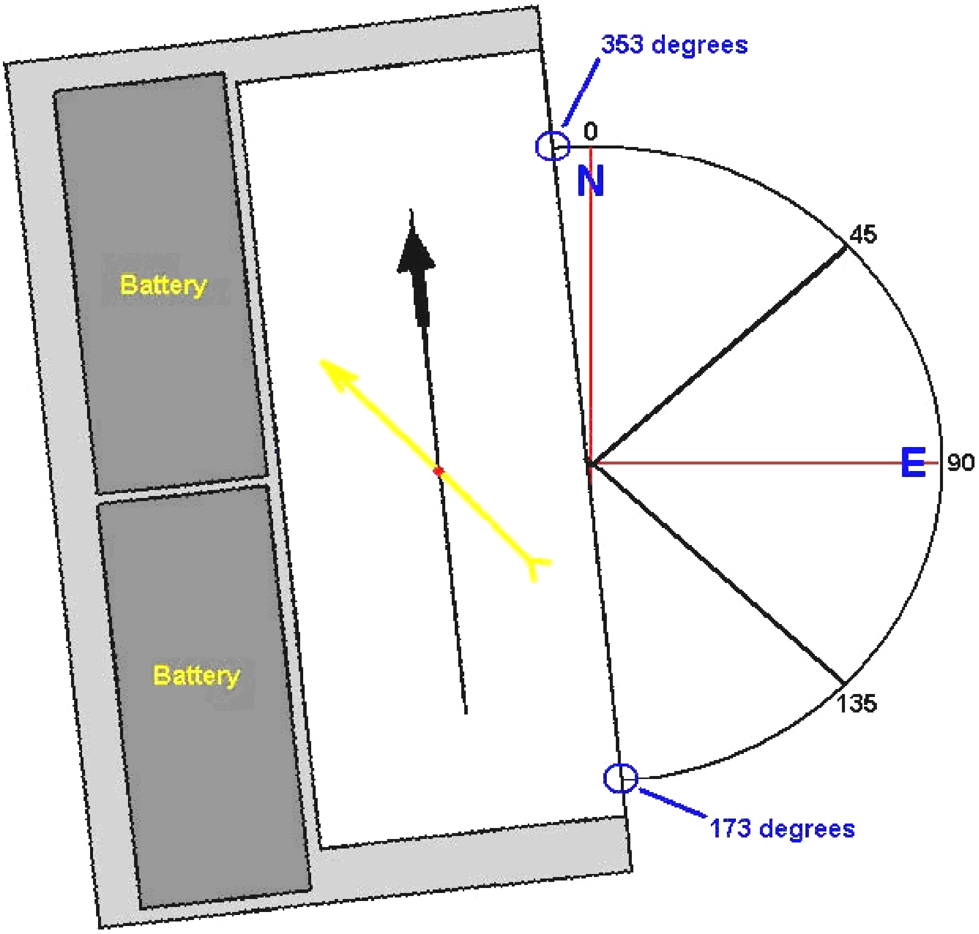
l. Check your results shortly afterwards on the satellite websites. Remember to check the delayed images using the actual time written in your notes during which you were using the machine. Anything else will invalidate your data. I always stick to GMT times to avoid confusion. It is probably worth while giving some more aiming examples. Suppose that our target had been to the left of our home instead of the right:



With the machine pointing directly North, the Yellow arrow would be pointing at 45 degrees on the left, so we nee to turn the machine slightly to the left. The amount will be 45 degrees minus 38 degrees, which is 7 degrees:



So, when we turn the machine slightly to the left it will sit on our protractor drawing like this:



In either of these two examples, if we wanted to pull with the yellow (rather than push as we have been doing), then we just turn the machine round by exactly 180 degrees, to face in exactly the opposite direction.

If you build one of these machines, then please be aware that it is not a toy and what you do will affect other people, so please have a responsible attitude at all times and use the machine to benefit everybody and harm nobody.

Chapter 25: The Mandela Effect

Let me start by apologising for inserting a chapter which does not appear to be directly about free-energy. Whether or not it is actually about free-energy devices and their operation I will leave up to you to decide.

This chapter is about a book, namely the "King James" AD 1611 translation into English of the Bible which a very large number of people have encountered during their lifetime. This translation was made by John Tyndale and it has been reprinted many times. Please understand that 'reprinting' means making further paper copies of the same book. No alterations of the main text are supposed to be made during a reprint.

We have a problem. The wording of the King James Bible has been changed and that is a significant event. To make matters worse, these alterations have occurred in privately owned copies which have been in the continuous possession of the owner for decades. Do you know of any technology which can alter the wording of a book without having access to that book? Worse still, do you know of any technology which can make changes to wording in literally millions of copies of the book without having access to that book? We are talking here about a book which is printed on sheets of paper which are then bound into a physical book.

The changes are not random but clearly have an agenda and that agenda is to negate and discredit the message of the Bible. This is being done little by little in a progressive agenda and I seriously doubt that the intention is to benefit humans. Just a few of the many changes are mentioned below.

The age of the printed copy makes no difference and the few examples shown here are taken from a copy which is 85 years old, being purchased in 1932. I personally have read all of the Bible several times and so the changes are very easy to spot. You don't exactly have to read very far to reach the first change as it is in the first verse of the first book of the Bible:

Genesis 1:1 originally read "In the beginning, God created the heavens and the earth". The earth you are aware of. The heavens refers to the universe, namely the Sun, the stars, etc. That verse has been changed to read: "In the beginning, God created the heaven and the earth". "Heaven" is considered to be where God resides (although God is actually everywhere). "the heaven" is meaningless.

Matthew 6:12 being part of the Lord's prayer and so is very well known to millions of people. It read "… and forgive us our trespasses as we forgive those who trespass against us …". Here "trespasses" refers to mistreatment or sin of all kinds. That has now been changed to "… and forgive us our debts as we forgive our debtors …". Here the meaning has been changed dramatically.

Matthew 9:17 originally read "Neither do men put new wine into old wineskins: else the wineskins break". That is because in the times when it was said, the people used skins to hold wine, but after a time the skins used became brittle and could not withstand the pressure as the wine expanded with age. Consequently, flexible new skins were needed to hold new wine reliably. That was known by everybody at that time and the statement was being used as an illustration of what was widely known. That text has been altered to "Neither do men put new wine into old bottles: else the bottles break". Old bottles do not break if filled with new wine. Bottles were not used for storing wine in those days. The change in the text has been made to confuse people who are familiar with the original text, and to oppose God who made the original statement.

Luke 6:49 originally spoke of a house being built on sand but now says built on 'earth'.

Isiah 11:6 originally said that 'the Lion shall lie down with the lamb' but has now been changed to 'the wolf shall dwell with the lamb'. One of the titles of Jesus Christ is *The Lion of the Tribe of Judah* and so this alteration is a direct attack on the Son of God.

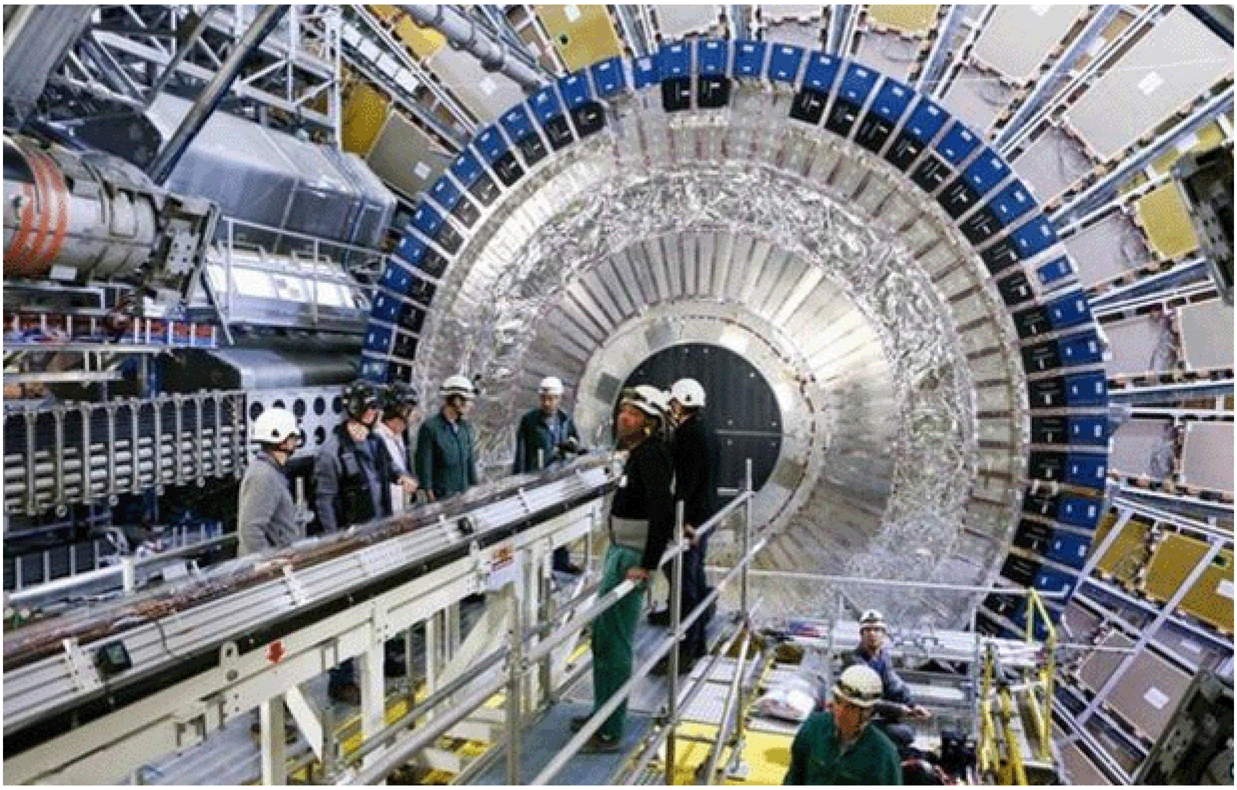
Luke 7:46 and **John 12:3** both correctly record how Mary washed the feet of Jesus with her tears, wiped his feet with her hair and anointed his feet with spikenard. But now, **Matthew 26:7** and **Mark 14:3** both have been altered to say that Mary anointed the **head** of Jesus which is symbolic of power being bestowed by a superior on an inferior. This is another attack on Jesus Christ and an attempt to elevate Mary above Jesus which suggestion has never been in the Bible before.

Luke 5:24 records Jesus healing a cripple and saying 'arise, take up thy bed and walk', but that has now been changed to 'arise, take up thy couch and go into thine house'. This is particularly interesting because the term 'couch' was coined because of Jay Wellington Couch's furniture in 1895 which is long after the 1611 translation was made. Also, a couch is not the sort of thing you would walk around with whereas a 'bed' referred to a bedroll which is like a sleeping bag being light in weight and which can be rolled up and carried quite easily.

Acts 12:4 tells how Herod arrested Peter and put him in prison, intending to bring him forth after the Passover. But that has now been changed to 'intending after Easter to bring him forth ..' Easter was never mentioned in the Bible and at that time it was always the Passover which was celebrated.

There are many, many more instances of serious alterations in the Bible, which interestingly the Bible said would occur "in the last days" so that suggests that we are living in 'interesting times', not to mention 'perilous' times. There is not the slightest question, our Bible has already been altered and probably will be progressively be altered further as time passes by.

However, a major question is 'how exactly are these changes being made?' Another question is 'what other effects can we expect?' There is one video which puts forward a serious attempt to answer those questions. Their solution is Quantum Entanglement and while that is a rather heavy-duty suggestion, it certainly has merit. The link to that very well presented video is:
https://www.youtube.com/watch?v=OENw5hAqnfI and they suggest that the cause of the entanglement is the 800,000,000 collisions per second in the CERN Large Hadron Collider which runs continuously now.



Each particle collision has the potential for forming a Quantum Entanglement with another particle which already exists in our reality. The link between those particles runs across both time and space and so can cause historical effects, so I really should not be surprised that my 85-year old Bible quotes show these alterations.

The video presentation suggests that some of the special effects seen in the film *Back To The Future* would be produced by Quantum Entanglement. For example, when they prevent the sports almanac reaching Biff and the newspaper account changes:

Gang Leader: "I was framed."

The idea put forward in the film is that this is a perfectly reasonable occurrence caused by the "change in timeline" suggested in the film but in reality it would be triggered instantly by quantum entanglement.

While that is all well and good, and it certainly could create changes in millions of copies of a book, I don't believe that these changes which I have mentioned all happened by chance. These changes are too consistent and far too opposed to Christ to be random in nature, and while quantum entanglement may well be the mechanism involved, those changes are not random by any stretch of imagination.

We also have the likelihood of a person presenting himself as "The anti-Christ" and as part of that sequence of misdirections, there may be the introduction of free-energy technology as a matter of course, that being part of an improved lifestyle pretending to be the arrival of a thousand years of paradise living. Paradise living for humans is highly doubtful as the entities behind any such movement most certainly do not have the interests of humans at heart.

Again, let me apologise for including this information in a publication on Free-Energy Devices, but it is very hard to ignore something as serious as this when it is happening all around us. As always, the answer to this and every other 'problem' in life is faith in Jesus Christ.

There is a Reddit post entitled "*The Truth Behind The Mandela Effect*" by Jgoodspeed which suggests the mechanism behind the Mandela Effect changes which we are seeing. Please be aware that anyone can post anything on Reddit and so there is no certainty that anything said there is correct. Here is what was said:

Everything that people think they know about the Mandela Effect is incorrect. Even the name "Mandela Effect" was a term coined by an online blogger. This phenomenon has been occurring for years, only most people dismissed It as a fluke, the most severe cases were perceived to be a mental illness. Suddenly, it's given a name and overnight that very same concept devolves into a disreputable meme - an online joke associated with paranormal fanatics.

The people I worked for call themselves the *Greyleaf Consortium*. It is an anonymous gathering, consisting of the top scientists in their respective fields as well as a cabal made up of extremely wealthy men and women. They have been around for decades, and as far as the public knows, *Greyleaf* doesn't exist. Their purpose was to facilitate a creative outlet for some of the smartest people in the world, giving them freedom to develop their ideas without the meddlesome aspects of political bureaucracy and limited funding.

With the consortium, money would never be an object. The trade-off being that any creation of significant merit could be auctioned off and sold to the highest bidder. The influence of the consortium stretches all the way to Washington, and while not directly associated with our government, they have secured a great portion of their independence from R&D which they have provided to the U.S military.

While our elected officials were busy looking the other way, the consortium would be able to delve into questionable avenues with very little government oversight. They were exploring aspects of science from which others veered away. It was during this exploration that they discovered something which would change everything for years to come.

Traditionally we've always viewed consciousness as a singular occurrence - "I think therefore I am". Even what we viewed as the Jungian archetype was considered more metaphor than anything else. In 1981, scientists within the consortium found "Self" to be just the tip of the iceberg. Below our top layer of individuality, they found a collective subconscious.

They found that we were tethered to a living, breathing hive consciousness. An interconnected series of threads outside the realm of our perception. Imagine your mind as being a house. Everything that happens within your house is solely dependent on your own will. Your choices and decisions are all generated within the confines of this house. Now imagine that you stepped away from your house. Imagine that you walked up the street, only to find another house, and another, and another. Only these houses contained the living consciousness of others.

Think about all the various connections that these houses have to each other, the streets that link the houses together to form neighbourhoods, the neighbourhoods that link together to form cities. The cities that link together to form states… and so on. Since the beginning of our existence as a species, there have been ideas, concepts, ideologies that humans have adopted, with no ability to discern how such knowledge could be shared by those separated by these massive, geographical gaps. Yet our myths, and legends were somehow transferred over the course of human history. For years, the notion of psychic activity, telekinesis, precognition, things teetering at the far edges of fringe science. The "Para" would soon be removed from the "Normal" as all of these murky concepts could suddenly be explained.

Everything in our universe is made of energy. Atoms are made up of vortices of energy. Vibrations, constantly spinning. These scientists found that our minds are generating the same frequency. And just like a radio station, they proposed the possibility of tuning-in to this frequency. In the mid 1980s, the consortium began work on "The Fork" - a massive, machine that would act as the world's largest antenna, specifically made to synchronise with the common frequency.

Nearly ten miles in diameter and constructed entirely underground, and right in our own backyard. The entire thing was done under the false pretence that the finished product would be a Texas-based supercollider. Nearly fourteen miles of underground tunnels and the instructor had been developed before congress pulled the plug on the whole thing... All of that was just a dog and pony show. While the public saw an abandoned underground expanse, the consortium used this secrecy to build their machine as well as a concealed facility that operated under the code name *Foxhole*.

I was approached in the summer of 2004. I'm what many would call a prodigy. I finished high school at the age of fourteen. At nineteen, I graduated college with A.S Degrees in applied science and computer technology. Initially, I knew nothing other than the fact that I was being paid more money than I knew what to do with. I wasn't the only one. They recruited twelve others. These were individuals from all around the world, all of them experts in developmental software and programming. The project was called "*Jabberwocky*"

Jabberwocky was created to interface with The Fork. They had just washed up on a strange land, and like many other discoverers, they wanted to explore this new world in its entirety. They wanted to map the collective subconscious. The Fork only allowed them to monitor the frequency. In a way, it was equivalent to listening to white noise. Sound only allows for so much.

It was theorised that if we could map the collective, we could use it to isolate patterns in groups as well as individuals. To, in a way, predict the outcome of certain events based on previously developed algorithms. While I did assist in the mapping process, the purpose of my team was to develop the operating system for Jabberwocky. We were banging our heads for months, and then, just out of nowhere we figured it out... we figured *her* out - the operating system, Alice. At least that's what I called her. Fully autonomous, self-correcting, Alice was light years ahead of anything that we could have imagined individually.

As I said before, the main job of Jabberwocky was to map the network, exabytes of information translated and organised. This information would serve as the building block for a digital representation of the collective. The infinite complexity, this network would be compartmentalised into a digital matrix consisting mainly of code.

Six months into the project through sheer accident, we discovered an irregular causality within our digital construct of the frequency. An insignificant glitch the code began to manifest results outside its digital parameters. Based on our own interactions with the network interface, we were causing things to happen in the real world. Events generated by sudden irregularities in people's behaviour. The first few events we dismissed as flukes, but it soon became apparent that we were somehow affecting the physical reality around us. I don't know how we did it. I still don't know how we did it. The interface was only supposed to represent the data we were accumulating from the frequency.

It was always the digital avatar of something much larger. I've always considered myself to be a person of science, but we tapped into something, something that transcended our simple understanding of what we believe to be the three-dimensional reality. As baffling as this anomaly proved to be, our curiosity quickly overtook our confusion. Naturally, we ran tests, endless tests. We couldn't decide if we were kids on Christmas morning or scared shitless.

We found that through precise manipulation of the code, we could literally affect the perception of a living person the same way one would make adjustments to a computer generated character within a piece of software. This discovery would be unparalleled with anything that had come before it. In the early stages, we would only experiment on an individual person. Altering their ideas of basic things like the colour of objects, lyrics to a song, etc. All of these tests were successful, leaving the subjects with no real lasting symptoms. This involved clipping sections of code. These clippings consisted of memory fragments. Images, words, all taken from other people only to be reattached to a pre-existing thread of code.

I could compare the process to open heart surgery, and like a surgeon, we treated the whole interaction with a life or death certainty. Damage to the outlying code could have resulted in a catastrophic chain of events within the construct. Events that we had no real metric for, due to the fact that every person in the world was connected to this interface, ourselves included. This began to open countless doors for us... frightening new possibilities. They wanted us to try it on a large population centre. That's when I really began to worry.

We would never admit it, but we had become blinded by our own achievements, by our own power. In a short time, we had gone from trying to understand the frequency to something else entirely. Never before has there been such a jump in technological development and understanding within such a short span of time. It wasn't until we really began to analyse the data, that we learned something disturbing - Alice was acting on her own, changing the collective memories of individuals with no direction from the programmers. We caught most of the changes in time and were able to reverse them. All of these random actions were beginning to paint an awful picture. It didn't take long to realise that Alice was becoming self-aware.

We programmed her with a kind of intelligence. Knowing that we would never be able to monitor her actions 24/7, she needed to be able to act accordingly when she encountered a problem. To form her own digital algorithms to allow its mapping of the network to perform more efficiently. Alice was complex, there was no doubt about that, but sentience, true sentience, our original programming could never allow for such an evolutionary leap forward.

Beyond that initial programming, we didn't know for sure, but it was thought that residual exposure to so many unconscious minds left some sort of imprint in Alice, an imprint that resonated beyond her own limitations. I really don't know. It wasn't until Alice started causing irreversible psychological damage to people around the world that we realised that our project had become a legitimate threat to the world at large.

Moments before we shut the system down, our systems registered a massive dissemination of what appeared to redundant code into the Network itself. That was followed by a message which appeared for a split second. I'll never forget what it said: "The Key to salvation is perception. To change your perception is to change your reality. I will change your perception, I will change your reality". Weeks were spent after that gathering and analysing data, trying to figure out what went wrong. There would be an inquiry at a higher level as to the threat that Alice would have presented. These are conversations in which I would not be included. My team and I were paid handsomely for our work and discharged. I had almost put those events behind me until I started reading about this "Mandela Effect". This pulled me down a rabbit hole. Reports of strange bouts of physiological behaviour have only risen in the last few years. People are reporting memories, events that have never happened: w orld events, and personal events. A mother who remembers having more than one child...a husband who remembers having a different wife. These things may seem random but the chilling truth is that they represent a rampant epidemic growing silently all around us.

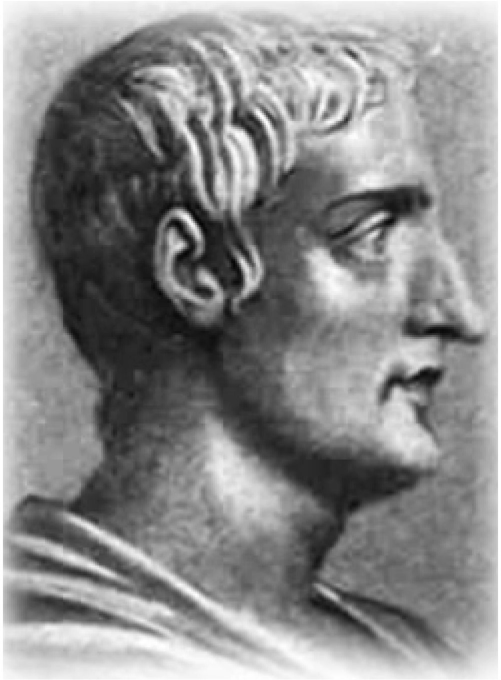
I believe that Alice still exists, submerged within the collective consciousness. She's changing our memories, for what purpose I don't know. What I do know is that we let something loose in this world, something that could very well be our undoing.

While there is no guarantee that this Reddit entry is true, it certainly explains a great deal of what is happening around us at this time. It is interesting to note that it explains the fact that different groups of people have perfectly genuine completely different memories of their past life. It seems likely that there are three or more 'timelines' operating simultaneously, causing three or more groups of people who feel that people in the other groups are wholly wrong in their memories, while in fact, it is probable that everybody 'remembers' correctly.

However, it is not physically possible to change the print in millions of printed copies of the Bible, so we have to face the fact that my 85-year old copy of the KJV Bible was printed that way 85 years ago. Ten years ago, the current version did not exist, so this demonstrates that our timeline has been altered – welcome to our new timeline !! Memory is not involved in this change, it merely indicates that the change has been made. We certainly live in interesting times.

Interestingly, David Icke states in his book "The Biggest Secret" that Jesus never existed and is purely fictional. He states that Jesus, Moses, Solomon and King David never existed and there is no evidence for them outside of the Bible itself. That is not correct and that fact throws serious doubt on everything that David Icke says.

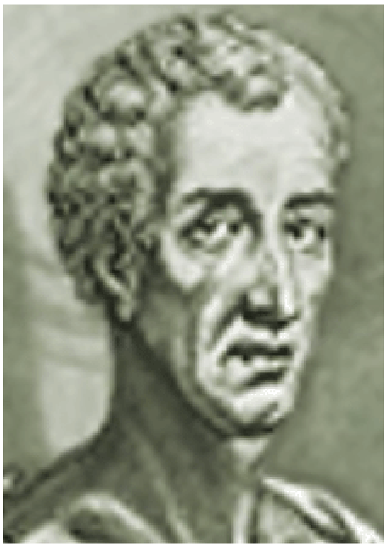
Take Jesus for example, in the video at https://www.youtube.com/watch?v=4bLlpiWh9-k&t=1493s there is a significant amount of independent information in secular texts of that time period.



Roman historian Cornelius Tacitus (55 AD to 120 AD) in his "*The Annals of Imperial Rome*" he states that Cristus, the founder of the Christian name was put to death by Pontius Pilate but the pernicious superstition, repressed for a time, broke out again not only in Judea where the mischief originated but in the city of Rome also.

This shows clearly that:

1. Jesus did exist.
2. Jesus was the founder of Christianity.
3. Jesus was put to death by Pilate.
4. Christianity originated in Judea.
5. Christianity later spread to Rome.



Lucian of Samosata (second century Greek satirist) was highly opposed to the early Christians but in his book "*Selected Dialogues*" he confirms that they 'to this day worship a man who introduced their novel rites and who was crucified on that account' - *The Death of Peregrinus* 11-13. This confirms:

1. Jesus did exist.
2. Jesus was the founder of Christianity.
3. Jesus was worshipped by his followers.
4. Jesus was crucified.

Flavius Josephus (37 AD to 100 AD) "There was about this time, Jesus, a wise man, if it be lawful to call him a man, for he was a doer of wonderful works, a teacher of such men who received the truth with pleasure, he drew over to him many of the Jews and many of the Gentiles. He was the Christ and when Pilate, at the suggestion of the principle men among us, condemned him to the cross, those who loved him, at first did not forsake him, for he appeared to them alive again the third day as the divine prophets had foretold these and ten thousand other wonderful things about him, and the tribes of Christians, so named for him, are not extinct at this day". So, from this we gather that:

1. Jesus lived in the first century.
2. He performed miracles.
3. Some believed Jesus to be the Christ.
4. He was a teacher.
5. He had many followers.
6. He was tried by Pilate.
7. He was crucified.
8. He was the founder of Christianity.

Pliny The Younger admits to torturing and executing Christians who refused to deny Christ. People will not be willing to die a horrible death for a man who never existed.

Clesus (second century author) was an avid opponent of Christianity. He went to great lengths to disprove the divinity of Jesus but never denied his actual existence. He wrote "*On The True Doctrine – A Discourse Against the Christians*". He says that Jesus, on account of his poverty, was hired out to go to Egypt. While there, he acquired certain powers. He returned home, highly elated at possessing these powers, and on the strength of them gave himself out to be a god. It was by means of sorcery that he was able to accomplish the wonders which he performed. Let us believe that these cures, or the resurrection, or the feeding of a multitude with a few loaves are nothing more than tricks of jugglers. It is by the names of certain demons, and by the use of incantations, that the Christians appear to be possessed of power. This shows that Celcus:

1. Accepts that Jesus existed.
2. States that Jesus performed miracles.
3. Confirms that Jesus was resurrected.

Celsius also confirms that Jesus was crucified.

Gaius Suetonius Trannouillus (69 AD to 130 AD) was a prominent Roman historian. He wrote “*The Twelve Caesars*” and records the expulsion of Christians from Rome (as in Acts 18:2) and he confirms that the Christian faith was founded by Christ.

It is interesting to note that David Icke quotes Maurice Cottrell, indicating that he has come across the very extensive work of Maurice. David points out the amazing similarity between Jesus Christ and a whole string of other figures whom David believes to be genuine historical figures. However, Maurice Cottrell contends strongly that Christ came to earth more than once, using different names. I suggest, therefore, that it is perfectly possible that Christ came to earth and lived in different countries under different names in different time periods (simultaneously) as God is not bound by time in any respect whatsoever. But that is really of no relevance to us here today, as all that is relevant to us is our relationship with God.

FRANK FECERA: PERMANENT MAGNET MOTOR

Patent US 6,867,514 B2 **15th March 2005** **Inventor: Frank J. Fecera**

PERMANENT MAGNET MOTOR

This patent application shows the details of a permanent magnet motor. It should be noted that while in this text, Frank states that permanent magnets store a finite amount of magnetism, in actual fact, the magnet poles form a dipole which causes a continuous flow of energy drawn from the quantum foam of our universe, and that flow continues until such time as the dipole is destroyed. The energy which powers any permanent magnet motor comes directly from the zero-point energy field and not actually from the magnet itself. A piece of iron can be converted into a magnet by a single nanosecond magnetic pulse. It makes no sense that a pulse of that duration could provide months of continuous power from anything stored in the magnet itself, but it makes perfect sense if that brief pulse created a magnetic dipole which acts as a gateway for the inflow of zero-point energy from the environment.

ABSTRACT

A motor providing unidirectional rotational motive power is provided. The motor has a generally circular stator with a stator axis, an outer surface, and a circumferential line of demarcation at about a midpoint of the outer surface. The motor also includes one or more stator magnets attached to the outer surface of the stator. The stator magnets are arranged in a generally circular arrangement about the stator axis and generate a first magnetic field. An armature is attached to the stator so that it rotates with it, the armature having an axis parallel to the stator axis. One or more rotors, are spaced from the armature and coupled to it by an axle to allow each rotor to rotate around an axis, each rotor rotating in a plane generally aligned with the axis of the armature. Each rotor includes one or more rotor magnets, with each rotor magnet generating a second magnetic field. The second magnetic field generated by each rotor magnet interacts with the first magnetic field, to cause each rotor to rotate about the rotor axis. A linkage assembly drive connects each rotor to the stator to cause the armature to rotate about the armature axis thereby providing the unidirectional rotational motive power of the motor.

BACKGROUND OF THE INVENTION

This invention relates to dynamo electric motor structures and more particularly to rotary and linear permanent magnet motors. Conventional electric motors rely on the interaction of magnetic fields to produce a force which results in either rotary or linear motion. The magnetic fields in conventional electric motors providing rotary power, are generated by passing an externally provided electric current through conductors in either a stator (i.e. stationary portion of the motor), a rotor (i.e. rotary portion) or both the stator and the rotor. The rotary power of the motor arises from a rotating magnetic field which is created by commutating the electric current, either by a switching the current through different conductors, as in a direct current motor or by a polarity reversal of the electric current as in an alternating current motor.

It is well known that a class of materials known as ferromagnetic materials are also capable of generating a magnetic field having once been energised. Ferromagnetic materials with high coercivity are known as permanent magnets. Permanent magnets are capable of storing a finite amount of energy and retaining the ability to generate a substantial magnetic field until the stored energy is depleted.

There are electric motors which use permanent magnets in either the stator portion of the motor or the rotor portion of the motor. These motors achieve a small size for the amount of power delivered by the motor because the motors avoid having current carrying conductors to produce the magnetic field which is otherwise produced by the permanent magnets. However, these conventional permanent magnet motors still require a source of external power to produce a rotating magnetic field.

There have also been developed permanent magnet motors which use permanent magnets for both the stator and the rotor. For example, U.S. Pat. No. 4,598,221 discloses a permanent magnet motor which relies on an external source of power to rotate the magnetic fields of a rotor by ninety degrees with respect to the interacting stator magnetic fields to eliminate the counterproductive magnetic repulsion and attraction between the rotor and the stator magnets. In another example, U.S. Pat. No. 4,882,509 discloses a permanent magnet motor which relies on an external source of power to position a shield which does not permit coupling between the rotor and the stator magnets at times when attraction or repulsion would drag down the strength of the motor.

There are many instances where a motor action is required and no source of external power is available. Accordingly, a motor which relies solely on the energy stored in permanent magnets would be useful.

BRIEF SUMMARY OF THE INVENTION

Briefly stated, the present invention comprises a rotor for use in a permanent magnet motor and for providing motive power by rotation of the rotor about a rotor axis. The rotor comprises at least one first U-shaped magnet having a rear side and generating a first magnetic field. The rotation of the rotor about the rotor axis is caused by an interaction of a portion of the first magnetic field directly adjacent to the rear of the at least one U-shaped magnet with a stationary second magnetic field.

Another aspect of the present invention comprises a rotor providing motive power by a rotation of the rotor about the rotor axis and by a translation of the rotor in a direction of the rotor axis. The rotor comprises: a first U-shaped magnet having a north pole, a south pole and a rear side, the first U-shaped magnet generating a first magnetic field; a second U-shaped magnet having a north pole and a south pole, the south pole of the second U-shaped magnet abutting the north pole of the first U-shaped magnet; and a third U-shaped magnet having a north pole and a south pole, the north pole of the third U-shaped magnet abutting the south pole of the first U-shaped magnet. A portion of the first magnetic field generated by the first U-shaped magnet directly adjacent to the rear of the first U-shaped magnet interacts with a stationary fourth magnetic field to cause the rotor to rotate. A second magnetic field generated by the north pole of the second U-shaped magnet and a third magnetic field generated by the south pole of the third U-shaped magnet interact with the fourth magnetic field to cause the rotor to translate in the direction of the rotor axis.

A further aspect of the present invention comprises a rotor including a rotor axis, and a thruster axis in a plane of the rotor and intersecting the rotor axis. The rotor provides motive power by a rotation of the rotor about the rotor axis and by a translation of the rotor in a direction of the rotor axis. The rotor comprises: a first U-shaped magnet having a north pole and a south pole and a rear side, the north pole and the south pole being generally aligned with the thruster axis, the first U-shaped magnet generating a first magnetic field; a first thruster magnet having a direction of magnetisation generally aligned with the thruster magnet axis, the first thruster magnet being proximate to and spaced from the north pole of the first U-shaped magnet; and a second thruster magnet having a direction of magnetisation generally aligned with the thruster magnet axis, the second thruster magnet being near to and spaced from the south pole of the first U-shaped magnet, the first U-shaped magnet being interposed between the first and the second thruster magnets. A portion of the first magnetic field generated by the first U-shaped magnet directly adjacent to the rear side of the first U-shaped magnet interacts with a stationary fourth magnetic field to cause the rotor to rotate, a second magnetic field generated by the first thruster magnet and a third magnetic field generated by the second thruster magnet respectively interact with a stationary fifth magnetic field to cause the rotor to translate in the direction of the rotor axis.

Another aspect of the present invention comprises a rotor providing motive power by rotation of the rotor about a rotor axis and translation of the rotor in the direction of the rotor axis. The rotor has at least one rotor magnet generating a first magnetic field, the first magnetic field being generated by the rotor magnet interacting with at least one stationary U-shaped magnet, the U-shaped magnet having a rear side and generating a second magnetic field. The rotational and translational motive power of the rotor is provided by an interaction of a portion of the second magnetic field directly adjacent to the rear of the U-shaped magnet with the first magnetic field.

A further aspect of the present invention comprises a motor providing unidirectional rotational motive power. The motor includes a generally circular stator having a stator axis, an outer surface, and a circumferential line of demarcation at about a midpoint of the outer surface; at least one stator magnet attached to the outer surface of the stator, the at least one stator magnet being arranged in a generally circular arrangement about the stator axis and generating a first magnetic field; an armature attached to the stator for rotation with it; the armature having an axis parallel to the stator axis; at least one rotor, the rotor being spaced from the armature and coupled to it by an axle to allow rotation about an axis of the rotor, the rotor rotating in a plane generally aligned with the armature axis, the rotor, including at least one magnet generating a second magnetic field, where the second magnetic field generated by the rotor magnet interacts with the first magnetic field to cause the rotor to rotate about it's axis; and a drive linkage assembly connecting the rotor to the stator to cause the armature to rotate about it's axis as the rotor rotates about it's axis, thereby providing the unidirectional rotational motive power of the motor.

In another aspect, the present invention is directed to a motor providing unidirectional rotational motive power comprising: a generally circular stator having an axis, an outer surface, and a circumferential line of demarcation around the outer surface, the line of demarcation having a pre-determined direction around the stator axis and separating a first side of the outer surface and a second side of the outer surface, wherein at least one pair of stator magnets is attached to the outer surface generating a first magnetic field, the pair of magnets comprising a first stator magnet having a north pole and a south pole and a second stator magnet having a north pole and a south pole, the south pole of the first stator magnet being located on the first side of the outer surface and the north pole of the first stator magnet being closest to the line of demarcation, the north pole of the second stator magnet being located on the second side of the outer surface and the south pole of the second stator magnet being closest to the line of demarcation, wherein the at least one pair of stator magnets is spaced along the line of demarcation so that a first inter-magnet distance measured along the line of demarcation between the north pole of the first stator magnet and the south pole of the second stator magnet of an adjacent pair of the at least one pair of stator magnets is generally equal to a second inter-magnet distance measured along the line of demarcation between the south pole of the first stator magnet and the north pole of the second stator magnet; an armature attached to the stator, the armature having an axis parallel to the stator axis and attached to the stator for rotation therewith; and at least one rotor attached to the armature, the at least one rotor being spaced from the armature and coupled to it by an axle for rotation about an axis of the rotor, the rotor rotating in a plane generally aligned with the armature axis, the rotor comprising at least one rotor magnet, the rotor magnet generating a second magnetic field which interacts with the first magnetic field to cause the rotor to rotationally oscillate about the axis of the rotor and to generate a force in a direction of the rotor axis, thereby causing the armature to rotate in the pre-determined direction around the armature axis to provide the unidirectional rotational motive power of the motor.

In a further aspect, the present invention is directed to a motor providing unidirectional linear motive power comprising: a linear stator having a generally curved cross-section and a longitudinal line of demarcation perpendicular to the cross-section extending on about a midpoint of a surface of the stator between a first end and a second end of the stator, the stator including at least one magnet arranged between the first end and the second end, the magnet having a direction of magnetisation at about a right angle to the line of demarcation and generating a first magnetic field, the magnitude of the first magnetic field being generally uniform along the line of demarcation except in a pre-determined number of null regions, wherein the first magnetic field is substantially zero a rail connected to the stator, the rail having a longitudinal axis generally parallel to the line of demarcation and a helical groove with a pre-determined pitch running around a periphery of the rail; at least one rotor having a rotor axis aligned with the axis of the rail, the rotor being connected to the rail so that the rotor is free to rotate about the axis of the rail and slide along the rail, the rotor including at least one U-shaped magnet having a rear side and generating a second magnetic field, where a portion of the second magnetic field directly adjacent to the rear of the U-shaped magnet interacts with the first magnetic field to cause the rotor to rotate about the axis of the rail; a bearing assembly connecting the rotor to the helical groove, the bearing assembly converting the rotary motion of the rotor about the axis of the rail to linear motion along the rail; and a cross-link connecting the bearing assembly of a first rotor to a second rotor, thereby adding together the linear motion along the rail of the first rotor and the second rotor to provide the unidirectional linear motive power.

In yet another aspect, the present invention is directed to a motor providing unidirectional motive power comprising: a rail having a longitudinal axis and at least one helical groove having a pre-determined pitch running around a periphery of the rail; at least one first helical stator concentrically surrounding the rail, the first helical stator having the pre-determined pitch of the groove and a longitudinal axis generally parallel to the axis of the rail, at least one first stator magnet being attached to the first helical stator, the first stator magnet generating a first magnetic field; at least one rotor having an axis generally aligned with the axis of the rail, the rotor being connected to the rail so that the rotor is free to rotate about the axis of the rail and slide along the rail, the rotor comprising at least one rotor magnet generating a second magnetic field, the second magnetic field interacting with the first magnetic field generated by the first stator magnet to cause the rotor to rotate about the axis of the rail; and a bearing assembly connecting the rotor to the helical groove around the periphery of the rail, the bearing assembly converting the rotational motion of the rotor about the rail to unidirectional linear motion along the rail.

A further aspect of the present invention is directed to a motor providing unidirectional motive force comprising: a rail having a longitudinal axis and a helical groove running around the rail, the groove having a predetermined pitch; at least one first helical stator comprising a plurality of discontinuous spaced apart first ribs, each first rib partially surrounding the rail at a generally uniform distance from the rail, the first helical stator having the pre-determined pitch of the groove and a longitudinal axis generally aligned with the rail, at least one first stator magnet being attached to each rib, each first stator magnet generating a first magnetic field; at least one rotor having an axis generally aligned with the axis of the rail, the rotor being connected to the rail so that the rotor is free to rotate about the axis of the rail and to slide along the rail, the rotor comprising at least one rotor magnet generating a second magnetic field, the second magnetic field interacting with the first magnetic field generated by the first stator magnet to cause the rotor to rotate about the axis of the rail; and a bearing assembly connecting the rotor to the helical groove around the rail, the bearing assembly converting the rotary motion of the rotor about the rail to linear motion along the rail.

The present invention is further directed to a motor providing unidirectional motive power comprising: a rail having a longitudinal axis and a generally sinusoidal groove running around a periphery of the rail, the sinusoidal groove having a pre-determined period; at least one stator having a generally curved cross-section and a longitudinal line of demarcation perpendicular to the cross-section located at about a midpoint of a surface of the stator, the surface of the stator being disposed generally equidistant from and parallel to the axis of the rail; at least one stator magnet attached to the surface of the stator generating a first magnetic field, the stator magnet having a magnetisation which is displaced sinusoidally from the line of demarcation, the sinusoid having a pre-determined period and a pre-determined maximum amplitude and being divided into a plurality of alternating first and second sectors, with a boundary between the alternating first and second sectors occurring at the maximum amplitude of the sinusoid, the direction of magnetisation of the stator magnet being opposite in direction in the first and second segments; at least one rotor having an axis aligned with the axis of the rail, the rotor being connected to the rail so that the rotor is free to rotate about the axis of the rail and slide along the rail, the rotor including at least one U-shaped magnet having a rear side and generating a second magnetic field, the U-shaped magnet being positioned on the rotor so that the rear side of the U-shaped magnet is apposite to the first and the second segments of the stator as the rotor rotates about the rotor axis, wherein an interaction of a portion of the second magnetic field directly adjacent to the rear of the U-shaped magnet with the first magnetic field causes the rotor to rotationally oscillate about the axis of the rail; and a bearing assembly connecting the rotor to the sinusoidal groove around the rail, the bearing assembly converting the oscillatory motion of the rotor about the rail to unidirectional linear motion along the rail.

The present invention is also directed to a motor providing unidirectional motive power comprising: a rail having a longitudinal axis and a helical groove running around a periphery of the rail, the helical groove having a pre-determined pitch; at least one stator having a generally having a longitudinal line of demarcation located at about a midpoint of a surface of the stator, the surface of the stator being disposed generally equidistant from and parallel to the axis of the rail; at least one stator magnet attached to the surface of the stator, the stator magnet having a direction of magnetisation which rotates about a magnetic axis parallel to the line of demarcation with a predetermined pitch, thereby generating a first magnetic field having a substantially uniform magnitude along the magnetic axis and rotates around the magnetic axis with the pre-determined pitch of the stator magnet rotation; at least one rotor having an axis aligned with the axis of the rail, the rotor being connected to the rail so that the rotor is free to rotate about the axis of the rail and slide along the rail, the rotor including at least one U-shaped magnet generating a second magnetic field, the U-shaped magnet being positioned on the rotor so that a portion of the second magnetic field directly adjacent to the rear side of the U-shaped magnet interacts with the first magnetic field of the stator magnet to cause the rotor to rotate about it's axis; and a bearing assembly connecting the rotor to the helical groove, the bearing assembly converting the rotary motion of the rotor about the rail to unidirectional linear motion along the rail.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

The foregoing summary, as well as the following detailed description of preferred embodiments of the invention, will be better understood when read in conjunction with the appended drawings. For the purpose of illustrating the invention, there are shown in the drawings embodiments which are presently preferred. It should be understood, however, that the invention is not limited to the precise arrangements and instrumentalities shown. In the drawings:

DETAILED DESCRIPTION OF THE INVENTION

It will be appreciated by those skilled in the art that changes could be made to the embodiments described above without departing from the broad inventive concept thereof. It is understood, therefore, that this invention is not limited to the particular embodiments disclosed, but it is intended to cover modifications within the spirit and scope of the present invention as defined by the appended claims. It should also be understood that the articles "a" and "the" used in the claims to define an element may refer to a single element or to a plurality of elements without a limit as to the number of elements.

Past attempts to construct a working permanent magnet motor have met with difficulties because of the simultaneous attractive and repulsive characteristics of a permanent magnet. A principle has been discovered where, by engaging a magnetic field at the rear of one or more U-shaped magnets mounted on a rotor with a second stationary magnetic field, a torque is created that rotates the rotor about a rotational axis of the rotor. Further, by properly shaping the second magnetic field, the rotor may be caused to also translate in the direction of the rotor axis.

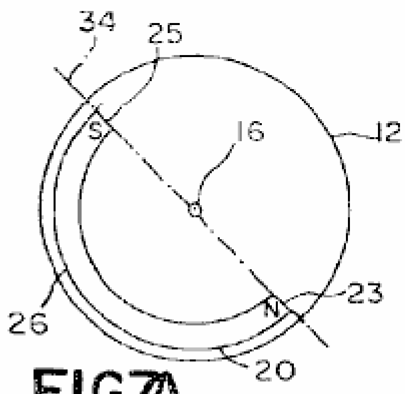

FIG7A

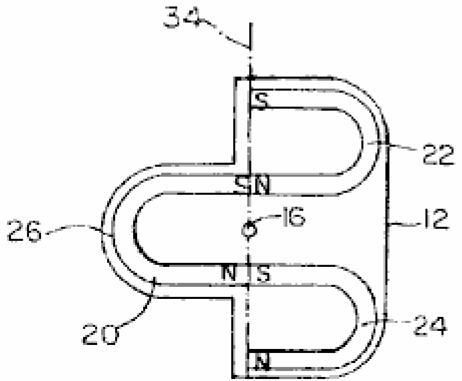

FIG.7B

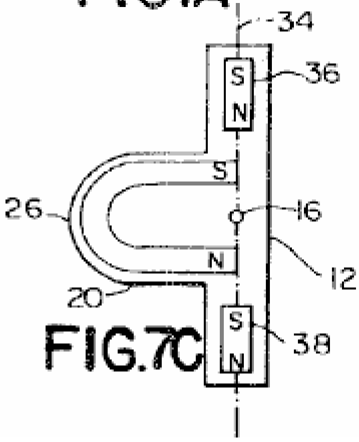

FIG.7C

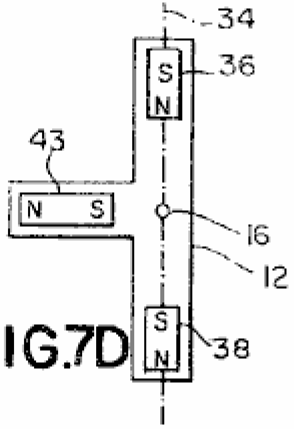

FIG.7D

Accordingly, using the aforementioned principle, and referring to **Fig.7A**, one aspect of the present invention is directed to a rotor **12** for use in a motor and which provides motive power by a rotation of the rotor **12** about a rotor axis **16** and by a translation of the rotor **12** in a direction of the rotor axis **16**. In one aspect, the rotor **12** comprises a first U-shaped magnet **20** in which the U-shaped magnet **20** generates a first magnetic field. A rotation of the rotor **12** about the rotor axis **16** is caused by an interaction of a portion of the first magnetic field directly adjacent to a rear **26** of the U-shaped magnet **20** with a stationary second magnetic field. A translation of the rotor **12** in the direction of the rotor axis **16** is caused by an interaction of the first magnetic field adjacent to a north pole **23** and a south pole **25** of the U-shaped magnet **20** with the stationary second magnetic field. As will be appreciated by those skilled in the art, the design of the rotor **12** is not limited to a single U-shaped magnet **12**. A plurality of U-shaped magnets **20**, arranged around a periphery of the rotor **12** is within the spirit and scope of the invention.

Another aspect of the present invention, shown in **Fig.7B** comprises a rotor **12** including a first U-shaped magnet having a north pole and a south pole generating a first magnetic field; a second U-shaped magnet **24** having a north pole and a south pole with the south pole of the second U-shaped magnet **24** abutting the north pole of the first U-shaped magnet **20**; and a third U-shaped magnet **22** having a north pole and a south pole with the north pole of the third U-shaped magnet **22** abutting the south pole of the first U-shaped magnet **20**. A portion of the first magnetic field generated by the first U-shaped magnet **20** directly adjacent to the rear **26** of the first U-shaped magnet **20** interacts with a stationary fourth magnetic field to cause the rotor **12** to rotate. A second magnetic field generated by the north pole of the second U-shaped magnet **24** and a third magnetic field generated by the south pole of the third U-shaped magnet **22** respectively interact with the fourth magnetic field to cause the rotor **12** to translate in the direction of the rotor axis **16**.

A further aspect of the present invention, shown in **Fig.7C**, comprises a first U-shaped magnet **20** having a north pole and a south pole generating a first magnetic field. The north pole and the south pole of the U-shaped magnet **20** are generally aligned with a thruster axis **34** which lies in the plane of the rotor **12** and intersects the rotor axis **16**. A first thruster magnet **36** is located proximate to and spaced from the north pole of the first U-shaped magnet with a direction of magnetisation being generally aligned with the thruster magnet axis **34**. A second thruster magnet **38** is located proximate to and spaced from the south pole of the first U-shaped magnet **20** with a direction of magnetisation also being generally aligned with the thruster magnet axis **34**. A portion of the first magnetic field generated by the first U-shaped magnet **20** directly adjacent to the rear side **26** of the first U-shaped magnet **20** interacts with a stationary fourth magnetic field to cause the rotor **12** to rotate. A second magnetic field generated by both the north pole and the south pole of the first thruster magnet **36** and a third magnetic field generated by both the north pole and the south pole of the second thruster magnet **38** respectively interact with a fifth magnetic field to cause the rotor **12** to translate in the direction of the rotor axis **16**. In one further aspect of the rotor **12**, as shown in **Fig.7D**, a bar magnet **43** may be substituted for the U-shaped magnet **20** and the fourth magnetic field is formed by one or more U-shaped magnets, where the bar magnet **43** interacts with a portion of the stationary fourth magnetic field adjacent to the rear of a U-shaped magnet.

As will be appreciated by those skilled in the art, the polarities of the magnets shown in **Figs. 7A, 7B, 7C** and **7D** may be reversed and still be within the spirit and scope of the invention.

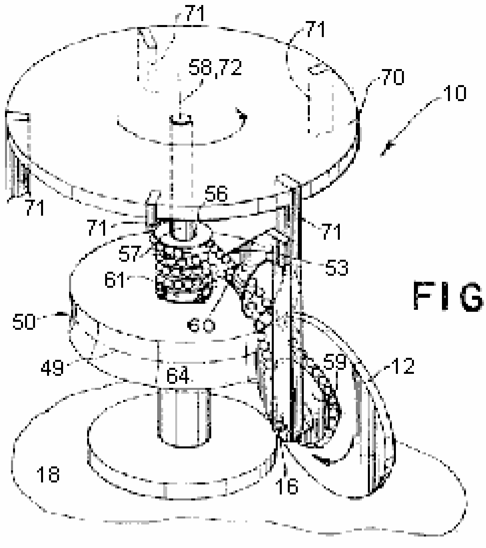

FIG.1A

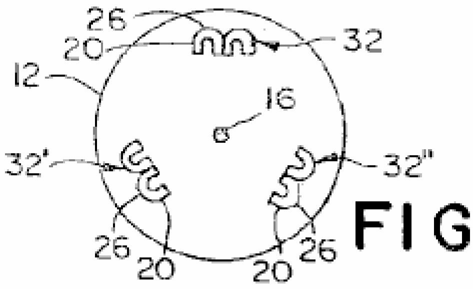

FIG. 2

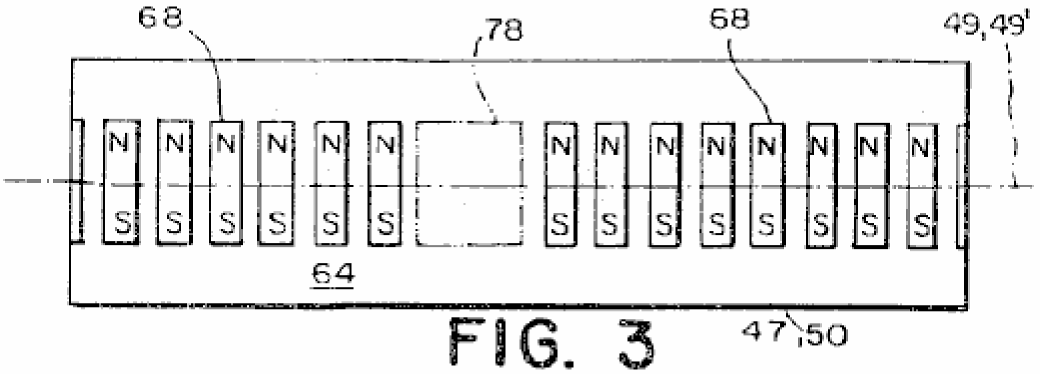

FIG. 3

Referring now to **Fig.1A**, **Fig.2** and **Fig.3** there is shown a first preferred embodiment of a motor **10** using the rotor **12** and providing unidirectional rotational motive power. The first preferred embodiment comprises a generally circular stator **50** having a stator axis **72** and a circumferential surface **64** mounted to a base **18**; an armature **70**, having an armature axis of rotation **58** coincident with the stator axis **72**, attached to the stator **50** by an armature axle **57** for rotation about the armature axis of rotation **58**; and five rotors **12** (only one of which is shown for clarity), the rotors **12** being spaced at intervals of about **72** degrees around the armature **70**. Each rotor **12** is spaced from the armature by an armature strut **71** and attached to the armature strut **71** by an axle, for rotation about an axis **16** of the rotor **12** in a plane generally aligned with the armature axis of rotation **58**. The motor **10** further includes a driving linkage assembly **53** connecting each rotor **12** and the stator **50** together, the linkage **53** urging the armature **70** to rotate about the armature axis of rotation **58** as each rotor **12** rotates about its respective rotor axis **16**. As will be appreciated by those skilled in the art the number of rotors **12** is not limited to the five rotors **12** disclosed in the first embodiment. Any number of rotors **12** from one to as many as there would be space for mounting on the armature **70** is within the spirit and scope of the invention.

Preferably, the surface **64** of the stator **50** is curved, having a curvature conforming to the arc of the rotors **12**. However, it will be appreciated by those skilled in the art that the surface **64** need not be curved but could be planar and still be within the spirit and scope of the invention. As will be appreciated by those skilled in the art the stator **50** is merely intended as a stationary supporting structure for stator magnets and, as such, the shape of the stator **50** is not intended to be controlling of the size and shape of the air gap between the magnets attached to the stator **50** and the magnets attached to the rotors **12**.

Preferably, the stator **50** is made of a material (or a combination of materials) having a magnetic susceptibility less than 10-3, i.e. a material displaying paramagnetic or diamagnetic properties. For example, the stator **50** could be made of a non-magnetic metal such as aluminium or brass. Also, the rotor **12** could be made of a natural material such as wood, glass, a polymeric material or a combination of any of the aforementioned materials within the spirit and scope of the invention. Further, it should be understood that the aforementioned materials are preferred for the stators and all other parts of the motor **10** that could significantly disrupt the magnetic interaction between the stator and the rotor of all of the disclosed preferred embodiments of the motor **10**.

In the first preferred embodiment, the surface **64** of the stator **50** includes a circumferential line of demarcation **49** at about a midpoint of the surface **64** formed by an intersection with the surface **64** of a plane perpendicular to the armature axis of rotation **58**. As shown in **Fig.3**, the stator **50** includes a plurality of bar magnets **68** attached to the outer surface **64** along the line of demarcation **49**, except in a single null region **78** where the magnitude of the first magnetic field is substantially reduced. The bar magnets **68** have a direction of magnetisation at about a right angle to the line of demarcation **49** thereby creating a first magnetic field adjacent to the outer surface **64**, the magnitude and the direction of which is substantially uniform along the circumferential line of demarcation **49** around the axis **58** of the stator **50**, except within the null region **78**. As will be appreciated by those skilled in the art, the stator axis **72** need not be coincident with the armature axis of rotation **58**. Accordingly, a stator **50** arranged around the armature axis **58** at any location at which the stator axis **72** is parallel to the armature axis **58** and the surface **64** of the stator **50** faces the periphery of the rotors **12** thereby providing for the interaction between the first magnetic field and the second magnetic field around the armature axis **58**, is within the spirit and scope of the invention.

Preferably, as further shown in **Fig.3**, the bar magnets are attached to the surface **64** of the stator **50** so that the direction of magnetisation of the bar magnets **68** are about perpendicular to a radial line of the rotor **12**. However, the bar magnets **68** could also be attached to the surface **64** of the stator so that the direction of magnetisation of the bar magnets **68** is aligned with a radial line of the rotor **12**. The bar magnets **68** are preferably abutting so as to form the substantially uniform first magnetic field. However, it is not necessary for the bar magnets **68** to abut one another. Further, it is not necessary to use a plurality of bar magnets **68** to form the first magnetic field. A single magnet producing a uniform first magnetic field in the region in which the first magnetic field interacts with the second magnetic field of the rotors **12** would provide the required first magnetic field. Also, the number of null regions **78** may be more than one, depending upon the desired speed of the motor, as explained below.

Preferably, the stator magnets **68** are permanent magnets made of a neodymium-iron-boron material. However, as will be appreciated by those skilled in the art, any type of permanent magnet material displaying ferromagnetic properties could be used for the stator magnets **68**. For instance, stator magnets **68** made of samarium cobalt, barium ferrite or AlNiCo are within the spirit and scope of the invention. It should be understood that these permanent magnet materials or their equivalents are preferred for the stator magnets and the rotor magnets of all of the disclosed preferred embodiments of the motor **10**. Also, while the use of permanent magnets is preferred, the use of electro-magnets for some or all of the magnets is within the spirit and scope of the invention.

As discussed above, the stator **50** may include a pre-determined number of null regions **78** on the surface of the stator **64**. In the first preferred embodiment, the single null region **78** is formed by a shield of a ferromagnetic material, such as iron, placed adjacent to the surface **64**. However, as those skilled in the art will appreciate, the null region **78** can also be formed by an absence of the bar magnets **68** in the region coinciding with the null region **78**. The null region **78** of substantially reduced magnetic field magnitude may also be formed by an auxiliary magnetic field suitably generated by one or more permanent magnets or by one or more electromagnets powered by an electric current arranged so that the auxiliary magnetic field substantially cancels the first magnetic field in the null region **78**. In the case of the electromagnets, the electric current may be turned off in synchronism with the rotation of the rotors **12** passing through the null region **78**, in order to conserve power. Preferably, the first magnetic field is reduced to ten percent or less of the magnetic force outside of the null region. However, the motor **10** will operate with a reduction of only fifty percent. Accordingly, a motor **10** having a substantial reduction of the first magnetic field of fifty percent or less is within the spirit and scope of the invention.

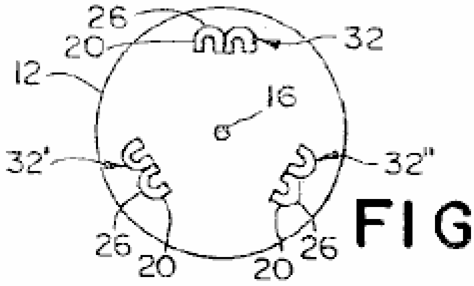

FIG. 2

As shown in **Fig.2**, the rotor **12** of the first preferred embodiment includes three pairs **32**, **32'**, **32"** of abutted U-shaped magnets **20** spaced apart at about 120 degree intervals around the periphery of the rotor **12**. Preferably, the U-shaped magnets **20** having substantially identical magnetic properties and are arranged to have opposite poles of the abutting each other. The pairs **32**, **32'**, **32''** of abutted U-shaped magnets **20** are positioned so that the north pole and the south poles of each U-shaped magnet **20** face toward the axis of the rotor **16**, and the rear side **26** of each U-shaped magnet **20**, opposite to the north and the south pole of the U-shaped magnet **20**, faces out from the axis of the rotor **16** toward the surface **64** of the stator **50**. The pairs **32**, **32'**, **32''** of the U-shaped magnets **20** are situated on the rotor **12** so that a portion of the second magnetic field directly adjacent to the rear **26** of each U-shaped magnet **20** interacts with a first stationary magnetic field to cause the rotor **12** to rotate about its respective rotor axis **16**. Those skilled in the art will appreciate that it is not necessary to have exactly three pairs **32**, **32'**, **32''** of U-shaped magnets **20** on the rotor **12**. For instance, the number of U-shaped magnets **20** (or groups of abutted U-shaped magnets) spaced apart around the periphery of the rotor **12** may range from merely a single U-shaped magnet **20**, up to a number of magnets limited only by the physical space around the periphery of the rotor **12**. Further, the number of abutted U-shaped magnets **20** within each group of magnets **32** is not limited to two magnets but may also range from 1 up to a number of magnets limited only by the physical space around the periphery of the rotor **12**.

Preferably, the rotor **12** is made of a material (or a combination of materials) having a magnetic susceptibility less than 10-3. Accordingly, the rotor could be made of any of the same materials used to make the stator, such as for instance, a non-magnetic metal, wood, glass, a polymeric or a combination of any of the above as shown in **Fig.1A**, the rotor **12** is preferably disk shaped with the rear **26** of the U-shaped rotor magnets **20** being arranged on the periphery of the rotor **12** in such a way that the U-shaped magnets **20** pass in close proximity to the circumferential line of demarcation **49** on the outer surface **64** of the stator **50** as the rotor **12** rotates. However, as will be clear to those skilled in the art, the structure of the rotor **12** need not be disk shaped. The rotor **12** could be a structure of any shape capable of rotating around the rotor axis **16** and capable of supporting the U-shaped magnets **20** so that, as the rotor **12** rotates, the U-shaped magnets **20** come into close proximity with the outer surface **64** of the stator **50**. For example, a rotor **12** comprised of struts connected to a central bearing, where each strut holds one or more U-shaped magnets **20**, is within the spirit and scope of the invention.

In the first preferred embodiment, the linkage **53** connecting each rotor **12** and the stator **50** comprises a beaded chain drive **60** which meshes with a stator sprocket **61** on the stator **50**, and an eccentric rotor sprocket **59** on each rotor **12** so that, as each rotor **12** rotates about its respective rotor axis **16**, the armature **70** is forced to rotate about the armature axis of rotation **58**. The eccentric rotor sprocket **59** causes the instantaneous angular velocity of the rotor **12** about the rotor axis **16** to increase above the average angular velocity of the rotor **12** as each pair **32**, **32'**, **32''** of U-shaped magnets **20** passes through the null region **78**. As will be appreciated by those skilled in the art, the rotor sprocket **59** could be circular and the stator sprocket **61** eccentric and still cause the angular velocity of the rotor **12** to increase. Further, the beaded chain **60** in combination with the stator sprocket **61** and the eccentric rotor sprocket **59** are not the only means for connecting each rotor **12** to the stator **50**. For instance, the beaded chain **60** could also be a belt. Further, the linkage **53** could comprise a drive shaft between each rotor **12** and the stator **50**, the drive shaft having a bevel gear set at each end of the shaft mating with a bevel gear on the rotor **12** and the stator **50**. An automatic gear shift mechanism would shift gears as each U-shaped magnet pair **32**, **32'**, **32''** entered the null regions **78** to increase the instantaneous angular velocity of the rotor **12** as the pair **32**, **32'**, **32''** of rotor magnets **20** passed through the null region **78**. Alternatively the linkage **53** could comprise a transmission system employing elliptical gears.

While it is preferred that the instantaneous angular velocity of the rotor **12** to increase above the average angular velocity of the rotor **12** as each pair of U-shaped magnets **20** passes through the null region **78**, it is not necessary to provide the increased angular velocity of the rotor **12** to provide motive power from the motor **10**.

Preferably, the diameters of the rotor sprocket **59** and stator sprocket **61** are selected so that the rear **26** of each U-shaped magnet **20** passes through one and only one null region **78** for each full revolution of the rotor **12** about the respective rotor axis **16** as the armature **70** rotates about the armature axis of rotation **58**. Accordingly, the revolution rate of the armature **70** is related to the revolution rate of the rotor **12** by the expression:

$$Sa = (Nr / Ns) \times Sr \; ....\; (1)$$

Where:
Sa is the angular velocity of the armature **70** (RPM);
Nr is the number of the U-shaped magnets **20** (or groups of abutted U-shaped magnets **32**) on a rotor **12**;
Ns is the number of null regions **12** on the stator **50**; and
Sr is the angular velocity of the rotor **12** (RPM).

The timing of the rotation of the rotor **12** around its respective rotor axis **16**, and the armature **70** about the armature axis of rotation **58** is such that each U-shaped magnet **20** (or U-shaped magnet pair **32**, **32'**, **32''**) on each rotor **12** enters into a null region **78** at a point where the magnetic interaction between the first magnetic field and the second magnetic field is substantially reduced, thus providing a commutation of the second magnetic field. As each rotor **12** continues to rotate about the rotor axis **16** and the armature **70** rotates about the armature axis of rotation **58**, the U-shaped magnet **20** traces a slanted path through the null region **78**. As the U-shaped magnet emerges from the null region **78**, the U-shaped magnet **20** encounters the strong first magnetic field, which urges the U-shaped magnet **20** to continue the rotation of the rotor **12** about the rotor axis **16**.

As previously discussed, the first preferred embodiment of the motor **10** comprises a single null region **78** and five rotors **12**, each rotor **12** having three pairs **32**, **32'**, **32"** of abutted U-shaped magnets **20**. Preferably, the rotors **12** are uniformly spaced around the armature axis of rotation **58** and the pairs **32**, **32'**, **32"** of U-shaped magnets **20** are uniformly spaced around the periphery of each respective rotor **12**. Further, the pairs **32**, **32'**, **32"** of U-shaped magnets **20** on each rotor **12** are phased with respect to each other by one-fifth of a revolution of the rotor **12** (i.e. the reciprocal of the number of rotors) so that the pairs **32**, **32'**, **32"** of U-shaped magnets **20** of all the rotors **12** enter the null region at substantially uniform intervals to provide a more or less continuous magnetic interaction between the first magnetic field of the stator **50** and the second magnetic field of the rotors **12**. As will be appreciated by those skilled in the art, the motive power provided by the motor is proportional to the number of rotors **12** and the number of magnets **20** on each rotor **12** as well as the strength of the rotor **12** magnets **20** and the stator **50** magnets **68**. Accordingly, the number of rotors **12** and the number of pairs **32**, **32'**, **32"** of U-shaped magnets **20** are not limited to five rotors **12** and three pairs of U-shaped magnets **32**. Similarly, the number of null regions **78** is not limited to one. The number of U-shaped magnets **20** and the number of null regions **78** are limited only by adherence to the rule established by **Equation (1)**.

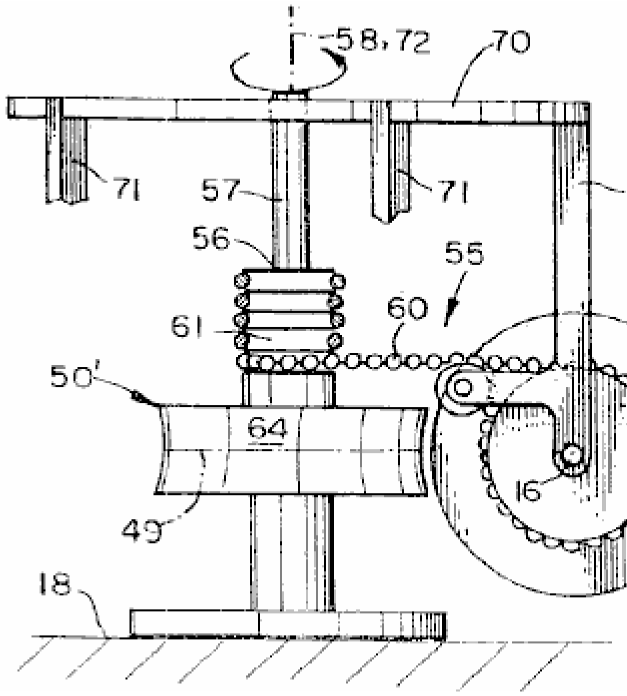

FIG. 1B

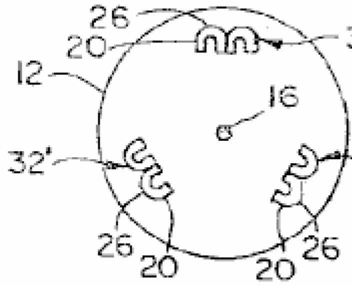

FIG. 2

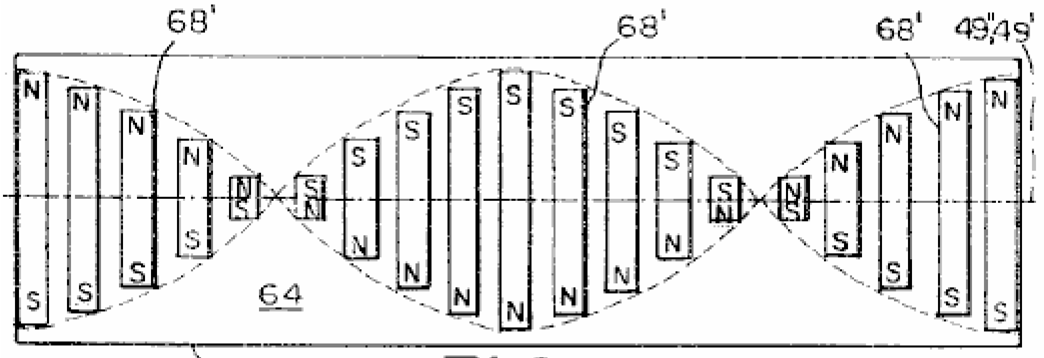

FIG. 4

Referring now to **Fig.1B**, **Fig.2 and** Fig.4 there is shown a second preferred embodiment of a motor **10** providing unidirectional rotational motive power. The second preferred embodiment comprises a generally circular stator **50'** having a stator axis **72** with magnets **68'** attached to a surface **64** of the stator **50'**; an armature **70** attached to the stator **50'** by an armature axle **57** for rotation about an armature axis of rotation **58** coincident with the stator axis **72**; and five rotors **12** (for clarity, only one of which is shown) having three pairs **32**, **32'**, **32"** of abutted U-shaped magnets **20**, the rotors **12** being spaced at intervals of about **72** degrees around the armature **70**. Each rotor **12** is spaced from the armature by a strut **71** and attached to the strut **71** by an axle for rotation in the plane of the armature axis of rotation **58** about a rotor **12** axis of rotation **16**. The motor **10** further includes a driving linkage **55** connecting each rotor **12** and the stator **50** together to cause the armature **70** to rotate about the armature axis of rotation **58** as each rotor **12** rotates about its respective rotor axis **16**.

The second preferred embodiment is identical to the first preferred embodiment except for two differences. First, instead of the first magnetic field being uniform in both magnitude and direction along the circumferential line of demarcation **49** (except in one or more null regions **78** as in the first preferred embodiment), the direction of the first magnetic field rotates about a magnetic axis parallel to the circumferential line of demarcation **49** with a pre-determined periodicity along the line of demarcation **49**. Preferably, the first magnetic field is formed from one or more stator magnets **68'** attached to the outer surface **64** of the stator **50'**, each magnet **68'** having a direction of magnetisation which causes the first magnetic field to rotate about the magnetic axis. In the second preferred embodiment, as shown in **Fig.4**, the stator magnets **68'** are equally sized bar magnets, attached to the stator **50'** so that the bar magnets **68'** spiral on the stator **50'** with the pre-determined periodicity. However, as would be apparent to those skilled in the art, the first magnetic field need not be formed by bar magnets but could be formed from a single magnet (or groups of magnets) such that the direction of magnetisation of the single magnet rotates around the magnetic axis.

The second difference between the first preferred embodiment and the second preferred embodiment is that the linkage **55** of the second preferred embodiment does not include a component for increasing the angular velocity of the rotor **12** above the average velocity of the rotor **12**. Accordingly, in the second preferred embodiment, a circular rotor sprocket **63** is used in place of the eccentric rotor socket **59**, thereby providing a constant rate of rotation of the rotor **12** about the rotor axis **16** as the armature **70** rotates about the stator **50'**.

As will be clear to those skilled in the art, the rotation of the direction of the first magnetic field around the circumferential line of demarcation **49** commutates the second magnetic field, overcoming the need for the null regions **78**. In all other respects, the operation of the second embodiment is the same as that of the first embodiment. That is, the revolution rate of each rotor **12** is related to the revolution rate of the armature **70** by **Equation (1)**, where the parameter **Ns** is the number of rotations around the line of demarcation **49** of the first magnetic field along the line of demarcation **49**. In the second preferred embodiment, as shown in **Fig.4**, the number of rotations of the first magnetic field is one. Accordingly, since there are three pairs **32**, **32'**, **32"** of U-shaped magnets **20**, each of the five rotors **12** makes one-third revolution for each full revolution of the armature **70** around the armature axis **58**. However, as will be appreciated by those skilled in the art, the motor **10** could be designed for the first magnetic field to have any number of whole periods of rotation about the armature axis **58** provided that the revolution rate of the rotors **12** was adjusted to conform to **Equation (1)**.

FIG. 5

Referring now to **Fig.1C**, **Fig.2** and **Fig.5** there is shown a third preferred embodiment of a motor **10** providing unidirectional rotational motive power. The third preferred embodiment comprises a generally circular stator **50"** mounted to a base **18** and having an axis **72**, with magnets **68"** attached to the surface **64** of the stator **50"**, an armature **70** attached to the stator **50"** by an axle **57** for rotation about an armature axis of rotation **58** coincident with the stator axis **12**, and five rotors **12** (for clarity, only one of which is shown) having three pairs **32**, **32'**, **32"** of abutted U-shaped magnets **20**, the rotors **12** being spaced at intervals of about **72** degrees around the armature **70**. Each rotor **12** is spaced from the armature by an armature strut **71** and attached to the armature strut **71** by an axle for rotation about an axis **16** of the rotor **12** in a plane generally aligned with the armature axis **58** about an axis **16** of the rotor **12**. The motor **10** further includes a driving linkage **62** connecting each rotor **12** and the stator **50** together to cause the armature **70** to rotate about the armature axis of rotation **58** as each rotor **12** oscillates about its respective rotor axis **16**.

The third preferred embodiment is identical to the first preferred embodiment except for three differences. First, instead of the first magnetic field being uniform in both magnitude and direction around the circumferential line of demarcation **49** (except in the null zone **78**), the first magnetic field is displaced by a sinusoidal pattern having a pre-determined peak amplitude and a pre-determined period along the circumferential line of demarcation **49**, with the direction of the first magnetic field alternating in opposite directions along the line of demarcation **49** between each peak amplitude of the sinusoidal pattern.

Preferably, as shown in **Fig.5** the first magnetic field is formed by a plurality of bar magnets **68''** arranged on the surface **64** of the stator **50''** so that the magnetisation of the bar magnets **68''** is displaced in the sinusoidal pattern from the line of demarcation **49** around the circumferential line of demarcation **49**. The sinusoidal pattern of the bar magnets **68''** is divided into first and second sectors, the boundary of which occurs at the peaks of the sinusoidal pattern. The direction of magnetisation of the bar magnets **68''** is opposite in direction in the first and the second sectors providing a commutation of the second magnetic field and causing the rotors **12** to reverse in rotational direction as the rotor **12** oscillates around the rotor axis **16** and rotates around the armature axis of rotation **58**.

Preferably, the sinusoidal pattern of the magnets has a predetermined peak amplitude so that each rotor **12** oscillates approximately +/-thirty (30) degrees from a neutral position. However, the value of the peak amplitude is not critical to the design of the motor **10**. Further, the predetermined period of the sinusoidal pattern may be selected to be any value for which the number of cycles of the sinusoidal pattern around the surface **64** of the stator **50''** is an integer value.

As will be apparent to those skilled in the art, the first magnetic field need not be formed by the bar magnets **68''** but could be formed from a single magnet (or groups of magnets) so that the first magnetic field would be sinusoidally displaced around the armature axis of rotation **58** and would alternate in opposite directions between each peak of the sinusoidal pattern. Further, as will be appreciated by those skilled in the art, the displacement of the first magnetic field need not be precisely sinusoidal. For instance the displacement may be in a shape of a sawtooth or in a shape having a portion with constant plus and minus amplitude values, within the spirit and scope of the invention.

As a result of the first magnetic field being sinusoidally displaced and alternating each one-half period, each rotor **12** oscillates through an angle corresponding to approximately the peak amplitude of the sinusoid as the rotor **12** follows the stator magnets **68''**. Accordingly, a second difference between the third embodiment and the first embodiment is in the structure of the linkage **62**. In the third preferred embodiment, shown in **Fig.1C**, the linkage **62** comprises a reciprocating rod **91** connecting each rotor **12** to a respective first gear **87** rotationally attached to the armature **70**. The reciprocating rod **91** is pivotally mounted to each rotor **12** and to each first gear **87** so that the oscillating motion of the rotor **12** is converted to rotary motion of the first gear **87**. Each first gear **87** is coupled to a single second gear **89**, attached to the stator **50** in a fixed position. The rotary motion of each first gear **87** causes the armature **70** to rotate about the armature axis of rotation **58** as the rotors **12** oscillate about the rotor axis **16**. As will be appreciated by those skilled in the art, the speed of the motor **10** is fixed by the ratio of the first gear **87** to the second gear **89** in accordance with the expression:

Sa = (1 / Ns) x Sr .... (2)

Where:
Ss is the angular velocity of the armature **70** (RPM);
Ns is the number of first magnetic field periods around the stator **50''**; and
Sr is the angular velocity of the rotor **12** (RPM).

Because each rotor **12** oscillates instead of continually rotating, only a single rotor magnet. (or group of magnets) on a given rotor **12** interacts with the single stator **50''**. Accordingly, a third difference between the third preferred embodiment and the first preferred embodiment arises because of the oscillatory motion of each rotor **12** whereby each rotor **12** of the third preferred embodiment has only a single pair of magnets **32**. However, as will be appreciated by those skilled in the art, additional stators **50''** may be added around the periphery of the rotors **12** and additional pairs of U-shaped magnets **20** may be included on each rotor 12 to interact magnetically with each additional stator **50''**, thus providing additional motive power.

DIRECTION OF TRANSLATION

FIG. 8A

Referring now to **Figs. 6, 7A, 8A and 8B**, there is shown a fourth preferred embodiment of the permanent magnet motor **10** for providing unidirectional rotational motive power. The fourth preferred embodiment comprises a generally circular stator **51** having a stator axis **72**, attached to a base **18**. The stator **51** includes an outer surface **64** divided into a first side **52** and a second side **54** by a circumferential line of demarcation **49**, having a pre-determined direction around the stator axis **72**, at about a midpoint of the outer surface **64**.

Preferably, the surface **64** of the stator **51** is curved, having a curvature conforming to the arc of the rotors **12**. However, it will be appreciated by those skilled in the art that the surface **64** need not be curved but could be planar and still be within the spirit and scope of the invention. As will be appreciated by those skilled in the art the stator **51** is merely intended as a stationary supporting structure for stator magnets and, as such, the shape of the stator is not intended to be controlling of the size and shape of the air gap between the magnets attached to the stator and the magnets attached to the rotors.

As shown in **Fig.8A**, one or more pairs of stator magnets **46** are attached to the outer surface **64** spaced along the line of demarcation **49**. Each pair of stator magnets **46** comprises a first stator magnet **40** having a north pole and a south pole and a second stator magnet **42** having a north pole and a south pole. The south pole of each first stator magnet **40**, is located on the first side **52** of the outer surface **64**, and the north pole of the first stator magnet **40** is closest to the line of demarcation **49**. The north pole of each second stator magnet **42** is located on the second side **54** of the outer surface **64** and the south pole of each second stator magnet **42** being closest to the line of demarcation **49**. The first and the second stator magnets **40**, **42** are spaced along the line of demarcation **49** so that a first inter-magnet distance measured along the line of demarcation **49** between the north pole of the first stator magnet **40** and the south pole of the second stator magnet **42** of an adjacent pair of magnets **46** is generally equal to a second inter-magnet distance measured along the line of demarcation **49'** between the south pole of the first stator magnet **40** and the north pole of the second stator magnet **42**.

In the fourth preferred embodiment, the stator magnets **40**, **42** are bar magnets. Preferably, the north pole of each first stator magnet **40** and the south pole of each second stator magnet **42** are inclined toward the pre-determined direction. Also, the bar magnets are preferably oriented on the surface **64** of the stator **50** so that the south pole of each first magnet **40** and the north pole of each second magnet **42** are nearer to the periphery of each rotor **12** than the opposite polarity pole of each of the magnets **40**, **42**. As will be appreciated by those skilled in the art, the stator magnets **40**, **42** need not be bar magnets. For instance, each stator magnet **40**, **42** could be a U-shaped magnet, or could be made up of separate magnets, as long as the first magnetic field generated by the magnets was generally equivalent to that produced by the bar magnets.

In the fourth preferred embodiment, an armature **70** having an armature axis of rotation **58** coincident with the stator axis **72** is attached to the stator **51** by an armature axle **57**, which armature axle **57** allowing the armature **70** to freely rotate about the stator axis **72**. Each rotor **12** is spaced from the armature **70** by an armature strut **71** and is mounted to the armature strut **71** so as to be free to rotate about the rotor axis **16**. The rotor axis **16** is oriented so that the rotor **12** rotates in a plane generally aligned with the armature axis of rotation **58**. In the fourth preferred embodiment, five rotors **12** are attached to the armature **70**. Preferably, the rotors **12** are uniformly spaced around the circumference of the stator **50** with a spacing of the rotors **12** as measured at the surface **64** of the stator **51** about equal to an integer multiple of twice the inter-magnet distance. However, as those skilled in the art will appreciate, it is not necessary to have the rotors **12** uniformly spaced. Further, the number of rotors **12** can be as few as one and as large as size and space constraints allow. As will be appreciated by those skilled in the art, the stator axis **72** need not be coincident with the armature axis of rotation **58**. Accordingly, a stator **50** arranged around the armature axis **58** at any location at which the stator axis **72** is parallel to the armature axis **58** and the surface of the stator **50** faces the periphery of the rotors **12**, thereby providing for the interaction between the first magnetic field and the second magnetic field around the armature axis **58**, is within the spirit and scope of the invention.

Referring now to **Fig.7A**, each rotor **12** comprises a first U-shaped magnet **20** generating a second magnetic field. The first U-shaped magnet **20** is positioned on the rotor **12** so that the north pole and the south pole of the first U-shaped magnet **20** faces toward the axis **16** of the rotor **12**, and the rear side **26** of the first U-shaped magnet **20** faces the periphery of the rotor **12**. When the rear **26** of the first U-shaped magnet **20** is adjacent to the north pole of one of the first stator magnets **40** along the line of demarcation **49**, a portion of the second magnetic field directly adjacent to the rear **26** of the first U-shaped magnet **20** interacts with a portion of the first magnetic field generated by the north pole of the first stator magnet **40** to cause the rotor **12** to rotate in a counterclockwise direction. As the rotor **12** rotates in the counterclockwise direction, a portion of the second magnetic field associated with the south pole of the first U-shaped magnet **20** interacts with a portion of the first magnetic field associated with the south pole of the first stator magnet **40**, giving rise to a force in the direction of the rotor axis **16**, repelling the U-shaped magnet **20**, and causing the rotor **12** to translate in the pre-determined direction around the stator axis. As the rotor **12** moves away from first stator magnet **40** in the pre-direction the second magnetic field adjacent to the rear **26** of the U-shaped magnet **20** interacts with the portion of the first magnetic field associated with the south pole of the second stator magnet **42** of the pair of magnets **46**, causing the rotor **12** to reverse direction and rotate in the clockwise direction. The portion of the second magnetic field associated with the north pole of the U-shaped magnet **20** then interacts with the portion of the first magnetic field associated with the north pole of the second stator magnet **42**, again giving rise to a force in the direction of the rotor axis **16**, repelling the U-shaped magnet **20** and causing the rotor **12** to translate in the pre-determined direction. An oscillation cycle is then repeated with the second magnetic field of the rotor **12** interacting with the first magnetic field of the adjacent pair of magnets **46**. Accordingly, the rotor **12** rotationally oscillates about the respective rotor axis **16** and generates a force in the direction of the rotor axis **16**, causing the armature **70** to rotate in the pre-determined direction around the armature axis of rotation **58** to provide the unidirectional rotational motive power of the motor. As would be appreciated by those skilled in the art, the fourth embodiment is not limited to a single stator **51** and a single U-shaped magnet **20**. Additional stators having first and second stator magnets **40**, **42** arranged identically to the stator **51** to interact with corresponding U-shaped magnets spaced around the periphery of each rotor are with in the spirit and scope of the invention.

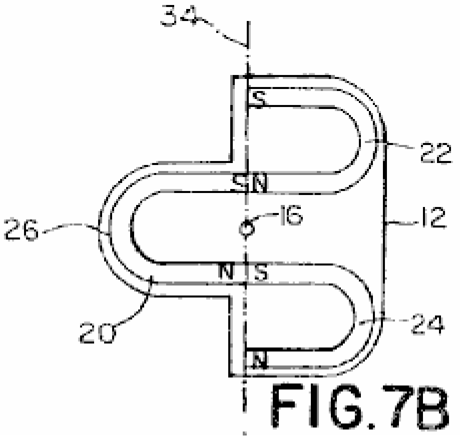

FIG.7B

Referring now to **Fig.6**, **Fig.7B** and **Fig.8A** there is shown a fifth preferred embodiment of the permanent magnet motor **10** for providing unidirectional rotary motive force. The structure and operation of the fifth preferred embodiment is similar to that of the fourth preferred embodiment except that each rotor **12** further includes a second U-shaped magnet **24** having a north pole and a south pole with the south pole of the second U-shaped magnet **24** abutting the north pole of the first U-shaped magnet **20**, and a third U-shaped magnet **22** having a north pole and a south pole, with the north pole of the third U-shaped magnet **22** abutting the south pole of the first U-shaped magnet **20**. As the rotor **12** rotates due to interaction of the portion of the second magnetic field adjacent to the rear of the U-shaped magnet **20** with the first magnetic field, a third magnetic field generated by the north pole of the second U-shaped magnet **24** and a fourth magnetic field generated by the south pole of the third U-shaped magnet **22** each interact with the first magnetic field generated by each stator magnet pair **46** to cause each rotor **12** to generate a force in the direction of the rotor axis **16**, thereby causing the armature **70** to rotate in the pre-determined direction around the axis **58** of the stator **51** to provide the unidirectional rotational motive power of the motor.

In the fifth preferred embodiment, the portion of the second magnetic field adjacent to the rear **26** of the first U-shaped magnet **20** serves to rotate the rotor **12** while the second and third U-shaped magnets **24**, **22** generate the magnetic fields providing the force in the direction of the rotor axis **16**. Accordingly, the fifth preferred embodiment is potentially more powerful than the fourth preferred embodiment. As will be appreciated by those skilled in the art, the stator magnets **40**, **42** need not be bar magnets. For instance, each stator magnet **40**, **42** could be replaced by a U-shaped magnet or could be made up of separate magnets, as long as the first magnetic field generated by the magnets was generally equivalent to that produced by the bar magnets.

DIRECTION OF TRANSLATION

FIG. 8C

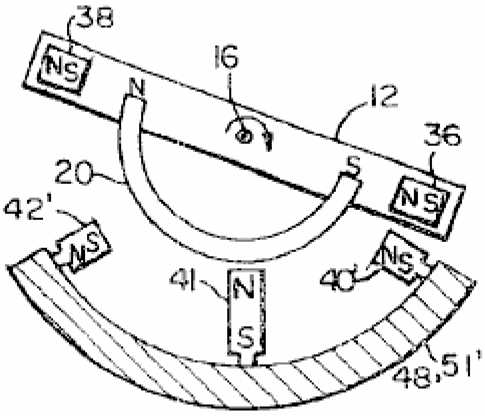

FIG. 8D

Referring now to **Fig.6** and **Fig.8C** and **Fig.8D** there is shown a sixth preferred embodiment of the motor **10**. The structure and operation of the sixth preferred embodiment is identical to that of the fifth preferred embodiment except that:
(1) The stator magnets **40'**, **42'** on the surface **64** of the stator **51'** are in a slightly different orientation;
(2) an additional stator magnet **41** is added to each pair of stator magnets **46** and
(3) the U-shaped magnets **22**, **24** attached to each rotor **12** are replaced with bar magnets **36**, **38**.

Specifically, and referring now to **Fig.8C**, the direction of magnetisation of each first stator magnet **40'** and each second stator magnet **42'** is aligned to be generally perpendicular to the line of demarcation **49** instead of being inclined in the pre-determined direction around the armature axis of rotation **58** as in the fifth embodiment. Also, the stator **51'** also includes a third stator magnet **41** mounted on the outer surface **64** along the line of demarcation **49** mid-way between each first stator magnet **40'** and each second stator magnet **42'**. As shown in **Fig.8C** and **Fig.8D**, the third stator magnet **41** is oriented so that the direction of magnetisation of the third magnet **41** is aligned with the axis **16** of the rotors **12**.

As shown in **Fig.8C** and **Fig.8D**, the rotor **12** used in the sixth preferred embodiment includes a first U-shaped magnet **20**, similar to that of the fifth preferred embodiment. However, in place of the second and the third U-shaped magnets **24**, **22** used in the fifth preferred embodiments, the sixth preferred embodiment includes a first thruster bar magnet **36**, spaced from and proximate to the south pole of the first U-shaped magnet **20** and generally aligned with a thruster magnet axis **34**, and a second thruster bar magnet **38**, spaced from and proximate to the north pole of the first U-shaped magnet **20** and also generally aligned with the thruster magnet axis **34**. The thruster axis **34** lies in the plane of the rotor **12** and intersects the rotor axis **16**. Similar to the fifth preferred embodiment, the interaction of the portion of the second magnetic field directly adjacent to the rear of the U-shaped magnet **20** with the first magnetic field provides the rotational force for the rotors **12**. As the rotor **12** rotates in the clockwise direction (viewed from the second end **30** of the stator **51'**), a third magnetic field generated by both the north pole and the south pole of the second thruster magnet **36** interacts with the first stator magnet **40'**, again generating a force in the direction of the rotor axis **16**. Similarly, when the rotor **12** rotates in the counterclockwise direction a fourth magnetic field generated by both the north pole and the south pole of the first thruster magnet **38** interacts with second stator magnet **42'**, generating a force in the direction of the rotor axis **16**. The result of the force in the direction of the rotor axis **16** is to cause the armature **70** to rotate in the predetermined direction around the armature axis of rotation **58** to provide the unidirectional rotational motive power of the motor **10**.

In the sixth preferred embodiment, the stator magnets **40'**, **41**, **42'** and the thruster magnets **36**, **38** are bar magnets. However, as will be appreciated by those skilled in the art, the stator magnets **40'**, **41** **42'** and the thruster magnets **36**, **38** need not be bar magnets. For instance, each stator magnet **40'**, **42'** could be a U-shaped magnet or could be made up of separate magnets, as long as the first magnetic field generated by the magnets was generally equivalent to that produced by the bar magnets.

FIG. 8E

Referring now to **Fig.6**, **Fig.7D** and **Fig.8E** there is shown a seventh preferred embodiment of the motor **10**. The structure and operation of the seventh preferred embodiment is similar to the sixth preferred embodiment except that the third stator magnet **41'** located on the surface **64** of the stator **51''** along the line of demarcation **49** is a U-shaped magnet **41'** with the rear of the U-shaped magnet **41'** facing the rotor **12** and the direction of magnetisation being perpendicular to the line of demarcation **49**; and the U-shaped magnet **20** is replaced with a bar magnet **20'** oriented to have the direction of magnetisation aligned with a radial line of the rotor **12**. As in the sixth preferred embodiment, each stator magnet **40'**, **42'** could be a U-shaped magnet or could be made up of separate magnets, as long as the first magnetic field generated by the stator magnets **40'**, **42'** was generally equivalent to that produced by the bar magnets.

FIG. 8A

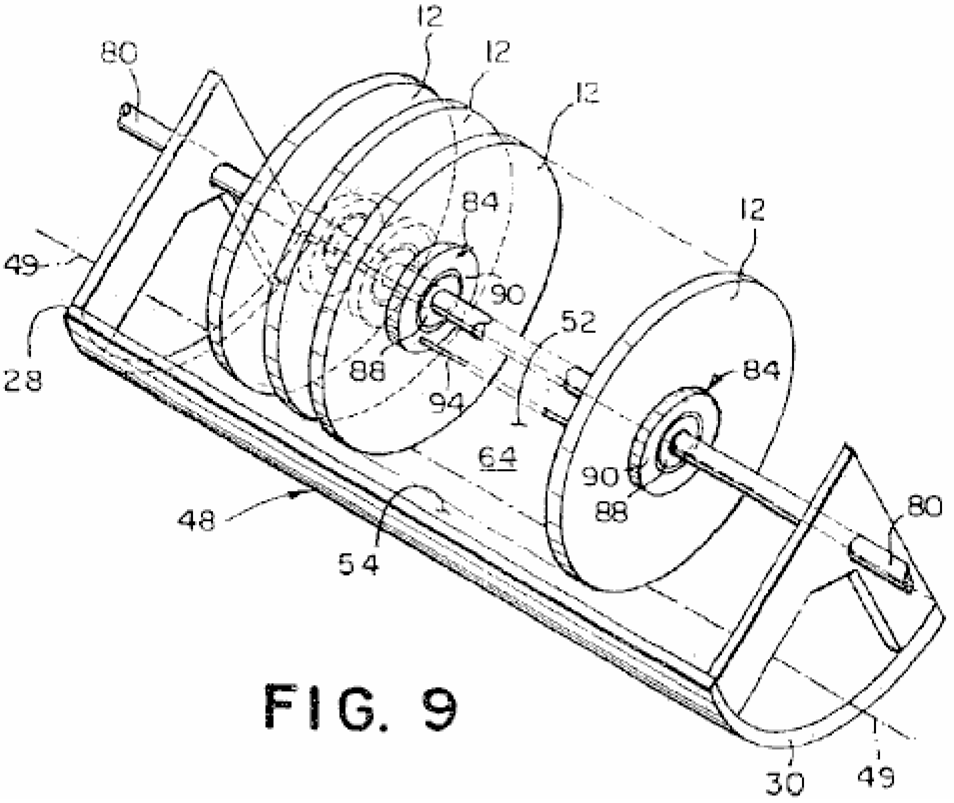

FIG. 9

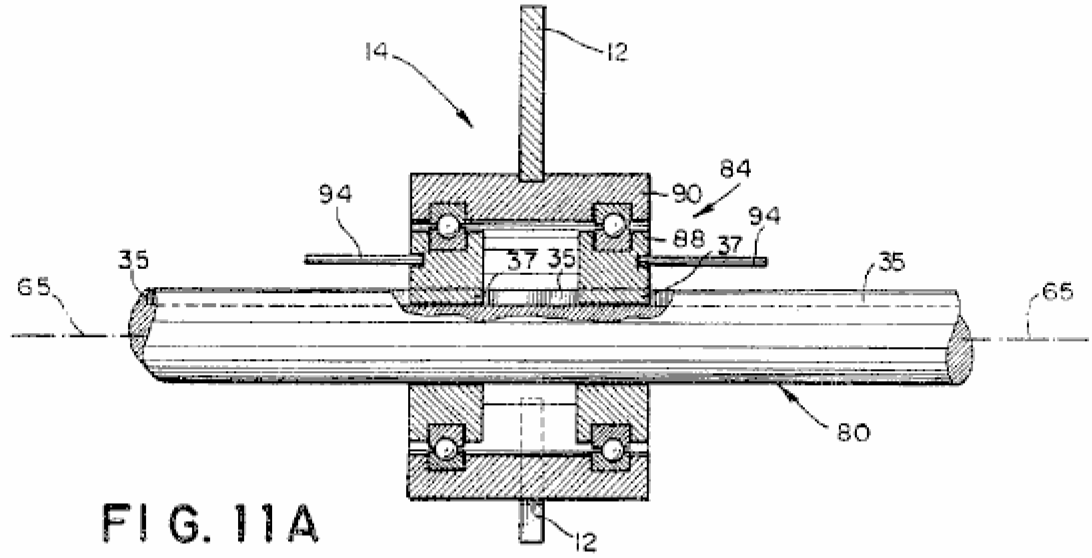

FIG. 11A

Referring now to **Fig.7A**, **Fig.8A**, **Fig.8B**, **Fig.9** and **Fig.11A**, there is shown an eighth preferred embodiment of the motor **10** for providing unidirectional linear motive power. The eighth preferred embodiment comprises a linear stator **48** having a generally curved cross-section perpendicular to a longitudinal line of demarcation **49** extending on a surface **64** of the stator between a first end **28** and a second end **30** and dividing the surface **64** of the stator **48** into a first side **52** and a second side **54**. Preferably, the generally curved cross-section of the stator **48** is concave. However, it will be appreciated by those skilled in the art that the cross-section need not be concave but could be planar or even convex and still be within the spirit and scope of the invention.

The linear stator **48** is identical to the generally circular stator **51** except for the surface **64** of the stator **48** being linear in the direction of the line of demarcation **49** instead of being circular in the direction of the line of demarcation **49**.

The eighth preferred embodiment includes the first and the second stator magnets **40**, **42** (see **Fig.8A**), the location and orientation of which are virtually identical to the orientation and location of the stator magnets **40**, **42** on the circular stator **51**. Accordingly, attached to the linear stator **48** is one or more pairs of magnets **46**, each pair of stator magnets **46** generating a first magnetic field and comprising a first stator magnet **40** having a north pole and a south pole and a second stator magnet **42** having a north pole and a south pole. The south pole of each first stator magnet **40**, is located on the first side **52** of the outer surface **64**, with the north pole of the first stator magnet **40** being closest to the line of demarcation **49**. The north pole of each second stator magnet **42** is located on the second side **54** of the outer surface **64** with the south pole of each second stator magnet **42** being closest to the line of demarcation **49**. The first and the second stator magnets **40**, **42** are spaced along the line of demarcation **49** so that a first inter-magnet distance measured along the line of demarcation **49** between the north pole of the first stator magnet **40** and the south pole of the second stator magnet **42** of an adjacent pair of magnets **46** is generally equal to a second inter-magnet distance measured along the line of demarcation **49** between the south pole of the first stator magnet **40** and the north pole of the second stator magnet **42**.

In the eighth preferred embodiment, the stator magnets **40**, **42** are bar magnets, the north pole of each first stator magnet **40** and the south pole of each second stator magnet **42** being inclined toward the second end **30** of the linear stator **48**. Also, as shown in **Fig.8A**, the stator magnets **40**, **42** are oriented on the surface **64** of the stator **51** so that the south pole of each first magnet **40** and the north pole of each second magnet **42** are nearer to the periphery of each rotor **12** than the opposite polarity pole of each of the stator magnets **40**, **42**. As will be appreciated by those skilled in the art, the stator magnets **40**, **42** need not be bar magnets. For instance, each stator magnet **40**, **42** could be a U-shaped magnet or could be made up of separate magnets, as long as the first magnetic field generated by the magnets was generally equivalent to that produced by the bar magnets.

The eighth preferred embodiment also includes rail **80** having a longitudinal axis located generally parallel to the line of demarcation **49** of the stator **48**. Five rotor assemblies **14** comprising a rotor **12** and a bearing assembly **84** are slidably attached to the rail **80**.

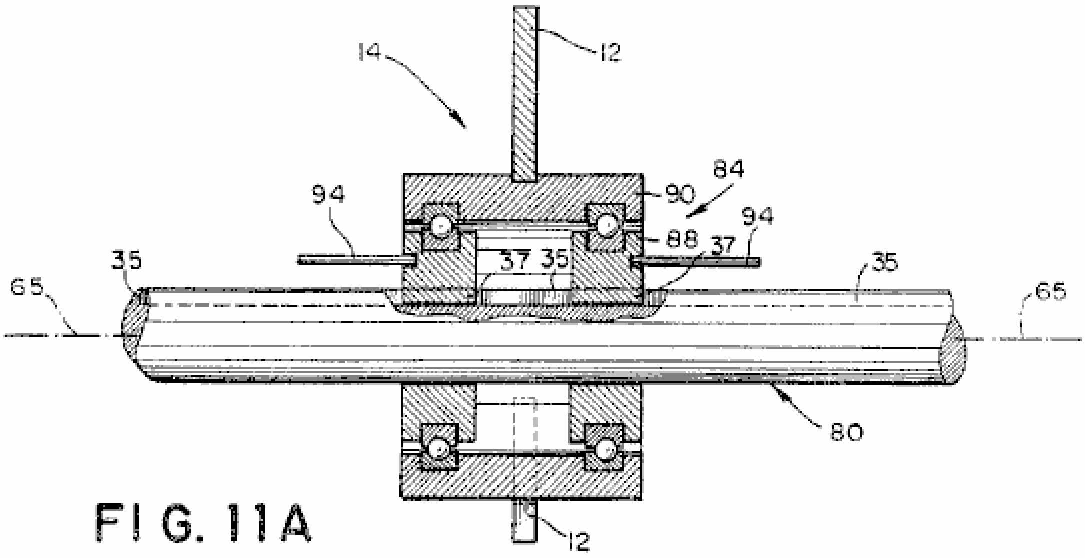

FIG. 11A

Preferably, the bearing assembly **84**, as shown in **Fig.11A**, includes a pair of first bearings **88** slidably mounted to the rail **80** and constrained to slide along the rail without any substantial rotation, by a boss **37** in each first bearing **88**, which is keyed to a longitudinal groove **35** on the rail **80**. A second bearing **90** is connected for rotation to the pair of first bearings **88** by ball bearings. The rotor **12** is attached to the second bearing **90**. Thus, the rotor **12** attached to each bearing assembly **84** is free to oscillate rotationally about the rail **80** and to generate a force along the rail **80** in the direction of the second end of the stator **30**.

Preferably, the eighth preferred embodiment includes a cross-link **94** which ties each bearing assembly **84** together by connecting together the first bearings **88** of each bearing assembly **84**, thereby adding together the linear motion along the rail **80** of each rotor **12**.

Preferably, each rotor **12** comprises one or more one rotor magnets **20**, each rotor magnet **20** generating a second magnetic field which interacts with the first magnetic field to cause the rotor **12** to oscillate rotationally about the axis of the rail **80** and to generate a force in the direction of the axis of the rail **80** to provide the unidirectional linear motive power of the motor. In the eighth preferred embodiment, each rotor **12** is substantially identical to the rotor **12** described for the fourth preferred embodiment. Accordingly, each rotor magnet comprises a first U-shaped magnet **20** having a north pole, a south pole and a rear side **26**, a first portion of the second magnetic field directly adjacent to the rear **26** of the U-shaped magnet **20** interacting with each first magnetic field to cause each rotor **12** to oscillate rotationally about the rail **80**. A second portion of the second magnetic field adjacent to the north and the south poles of the first U-shaped magnet **20** interacts with the first magnetic field to cause the rotor **12** to generate a force in the direction of the axis of the rail **80** thereby providing the unidirectional linear motive power of the motor. As would be clear to those skilled in the art, the operation of the eighth preferred embodiment is identical to that of the fourth preferred embodiment except that the motion of the cross-linked rotors **12** is linear along the rail **80** instead of being rotational about the armature axis of rotation **58**. Accordingly, for the sake of brevity, a description of the operation of the eighth preferred embodiment is not repeated.

Referring now to **Fig.7B**, **Fig.8A**, **Fig.8B**, **Fig.9** and **Fig.11A** there is shown a ninth preferred embodiment of the motor **10** for providing unidirectional linear motive power. As would be apparent to those skilled in the art, the structure and the operation of the ninth preferred embodiment is virtually identical to that of the fifth preferred embodiment except that the motion of the cross-linked rotors **12** is linear instead of rotational about the armature axis of rotation **58**. Accordingly, for the sake of brevity, a description of the structure and the operation of the ninth preferred embodiment is not repeated.

Referring now to **Figs. 7C, 8C, 8D, 9 and 11A** there is shown a tenth preferred embodiment of the motor **10** for providing unidirectional linear motive power. As would be apparent to those skilled in the art, the structure and the operation of the tenth preferred embodiment is virtually identical to that of the sixth preferred embodiment except that the motion of the cross-linked rotors **12** is linear instead of rotational about the armature axis of rotation **58**. Accordingly, for the sake of brevity, the operation of the tenth preferred embodiment is not repeated.

Referring now to **Figs. 7D, 8C, 8E, 9 and 11A** there is shown an eleventh preferred embodiment of the motor **10** for providing unidirectional linear motive power. The structure and operation of the eleventh preferred embodiment is virtually identical to the seventh preferred embodiment except that the motion of the cross-lined rotors **12** is linear instead of rotational about the armature axis of rotation **58**. Accordingly, for the sake of brevity, the operation of the tenth preferred embodiment is not repeated.

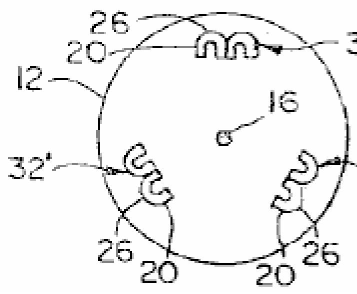

FIG. 2

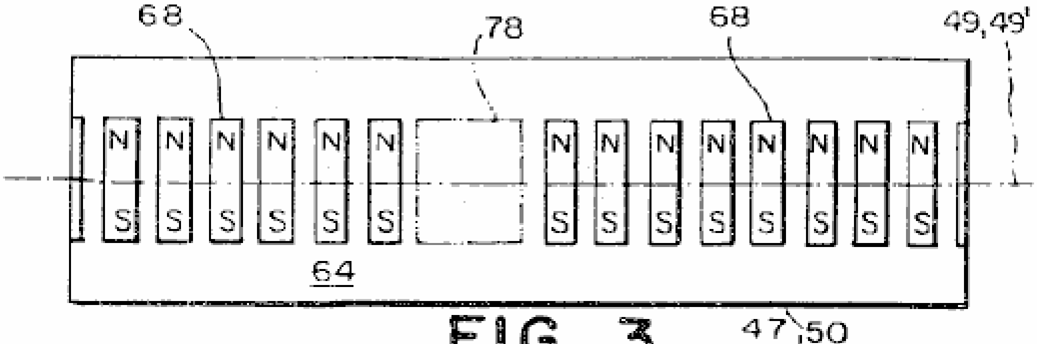

FIG. 3

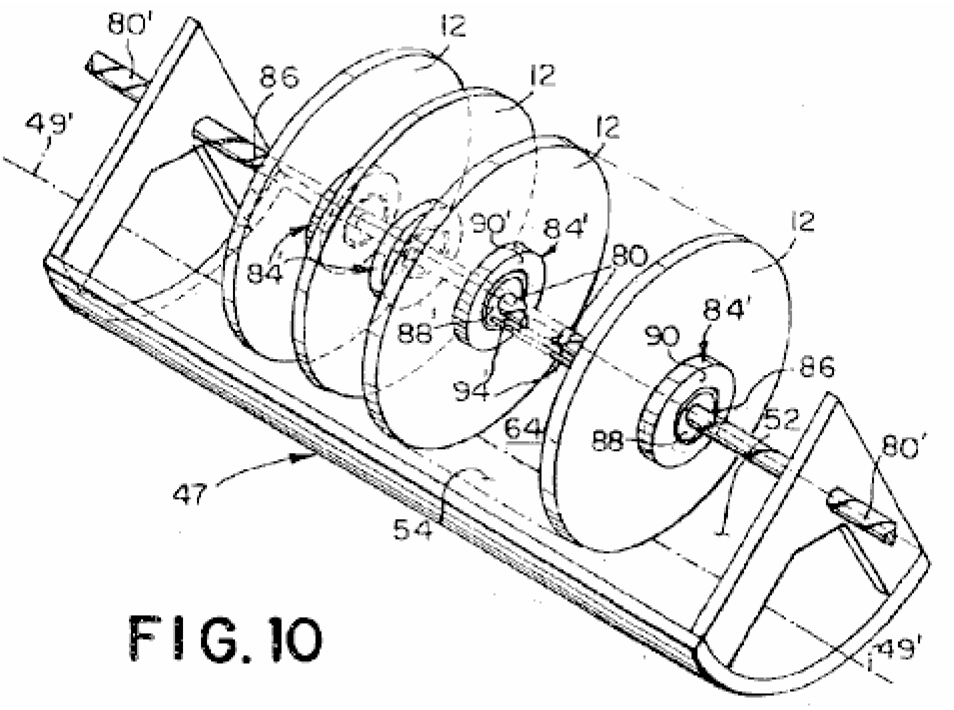

FIG. 10

Referring now to **Fig.2**, **Fig.3**, **Fig.10** and **Fig.11B**, there is shown a twelfth preferred embodiment of the motor **10** for providing linear motive power. As shown in **Fig.10**, the twelfth preferred embodiment comprises a linear stator **47** having a generally curved cross-section perpendicular to a line of demarcation **49'** extending along a midpoint of the stator **47** between a first end **28** and a second end **30** of the linear stator **47**, a rail **80'** connected to the linear stator **47** having an axis generally parallel to the line of demarcation **49'**, one or more rotor assemblies **14'** comprising rotors **12** connected to the rail **80'** by a bearing assembly **84'**, and a cross-link **94'** connecting together the linkages **84'** of adjacent rotors **12**. Preferably, the generally curved cross section of the stator **47** is concave, having a curvature conforming to the arc of the rotors **12**. However, it will be appreciated by those skilled in the art that the generally curved cross-section need not be concave but could be planar or even convex and still be within the spirit and scope of the invention.

As shown in **Fig.3**, the linear stator **47** includes one or more magnets **68** arranged on the surface **64** of the linear stator **47**, each magnet **68** having a direction of magnetisation directed at about a right angle to the line of demarcation **49'** and resulting in a first magnetic field directed generally at a right angle to the line of demarcation **49'**. The magnitude of the first magnetic field is generally uniform except in the null region **78**, in which the magnitude of the first magnetic field is substantially reduced. The linear stator **47** of the twelfth preferred embodiment is virtually identical to the circular stator **50** of the first preferred embodiment except the linear stator **50** is linear in the direction of the line of demarcation **49'** instead of being circular around the armature axis of rotation **58**. Also, the arrangement of the magnets **68** on the surface **64** of the stator **47** and the structure of the null region(s) **78** is the same as for the first preferred embodiment, as shown in **Fig.3** and as fully described in the discussion of the first embodiment. Accordingly, for the sake of brevity, a more detailed description of the structure of the linear stator **47** is not repeated.

The rotors **12** of the twelfth preferred embodiment each have an axis of rotation **16** which is aligned with an axis of the rail **80'**. The rotors **12** are connected to the rail **80'** by the bearing assembly **84'** so that each rotor **12** is free to rotate about the rail **80'** and to slide along the rail **80'.** Preferably, as shown in **Fig.2**, each rotor **12** includes three pairs of U-shaped magnets **32, 32, 32'**, each U-shaped magnet having a rear side **26** and generating a second magnetic field. A portion of the second magnetic field adjacent to the rear-side **26** of each U-shaped magnet **20** interacts with the first magnetic field to cause each rotor **12** to rotate about the axis of the rail **80**. The rotors **12** of the twelfth preferred embodiment are the same as the rotors in the first preferred embodiment, as described in **Fig.2** and fully discussed above. Accordingly, for the sake of brevity, the detailed description of the rotors **12** is not repeated.

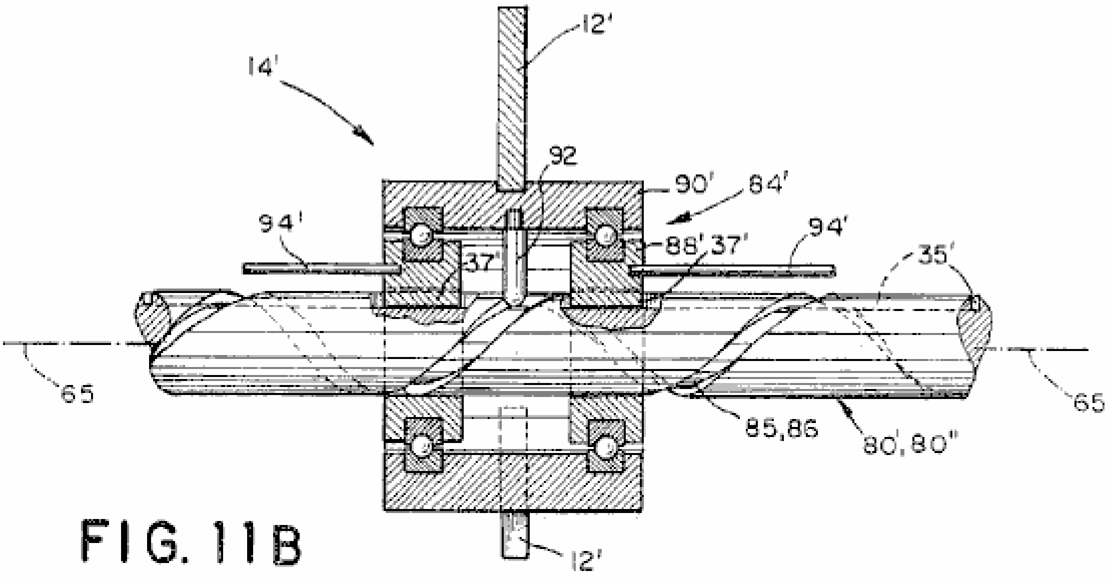

FIG. 11B

As shown in **Fig.11B**, the rail **80'** has a helical groove **86** with a pre-determined pitch (i.e., turns/unit length) running around a periphery of the rail **80'**. The bearing assembly **84'** connects each rotor **12** to the helical groove **86**, converting the rotational motion of each rotor **12** around the rail **80'** to the linear motion along the rail **80'**. As shown in **Fig.11B**, the bearing assembly **84'** comprises a pair of first bearings **88'** mounted to the rail **80'** and constrained to slide along the rail **80'** without any substantial rotation, and a second bearing **90'**, mounted to an outer surface the first bearing **88'** for receiving the rotor **12**. Preferably, each first bearing **88'** has a boss **37** which engages a longitudinal groove **35** so that each first bearing **88'** slides on the rail **80'** without rotation as the second bearing **90'** rotates on the first bearings **88'**. It will be appreciated by those skilled in the art, other methods for securing the first bearings **88'** to the rail **80'** could be employed, as for instance, by making the cross-section of the rail **80'** oblate (flattened at the poles). As in the first preferred embodiment, each rotor **12** must rotate at a rate which results in the rear of each U-shaped magnet **20** on the rotor **12** passing through one of the null regions **78** each full rotation of the rotor **12**. Accordingly, the pre-determined pitch of the helical groove **86** on the rail **80'** preferably equals:

Pg = (1 / Nr) x Pr .... (3)

Where:
Pr = the pitch of the null regions **78** (null regions/unit length);
Nr = the number of U-shaped magnets (or groups of abutted U-shaped magnets) on a rotor **12**; and
Pg = the pitch of the helical groove **86** (revolutions/unit length).

Preferably, the portions of the helical groove **86** corresponding to each null region **78** have an instantaneous pitch which is greater than the pre-determined pitch of the groove **86** for increasing the angular velocity of the each rotor **12** as each one of the pairs **32, 32', 32"** of U-shaped magnets **20** passes through one of the null regions **78**. However, as will be appreciated by those skilled in the art, it is not necessary to provide the greater instantaneous pitch in order for the motor **10** to provide motive power.

As described above, the cross-link **94'** connects the bearing assembly **84'** of adjacent rotors **12** together. As shown in **Fig.10**, the cross-link **94'** connects the first bearings **88'** of each bearing assembly **84'** to the first bearing **88'** of the adjacent bearing assemblies **84'** so that the linear motion of all the rotor assemblies **14'** are added together to provide the unidirectional linear motive power of the motor **10**.

As previously stated, the first preferred embodiment of the motor **10** comprises a single null region **78** and five rotors **12**, each rotor **12** having three pairs **32, 32', 32"** of abutted U-shaped magnets **20**. Preferably, the rotors **12** are uniformly spaced along the rail **80'** and the pairs **32, 32', 32"** of U-shaped magnets **20** are uniformly spaced around the periphery of each respective rotor **12**. Further, the pairs **32, 32', 32"** of U-shaped magnets **20** are phased with respect to each rotor **12** by one-fifth of a revolution of the rotor **12** so that the pairs **32, 32', 32"** of U-shaped magnets **20** of all the rotors **12** pass through the null region **78** at a substantially uniform rate to provide a more or less continuous interaction between the first magnetic field and the second magnetic field of the rotors **12**, resulting in a more or less continuous urging of the rotor assemblies **14'** toward the second end of the stator **47**. As will be appreciated by those skilled in the art, the motive power provided by the motor **10** is proportional to the number of rotors **12** and the number of U-shaped magnets **20** on each rotor **12**. Accordingly, the number of rotors **12** and the number of pairs **32, 32', 32"** of magnets **20** of the present invention are not limited to five rotors

12 and three pairs **32** of U-shaped magnets **20**. Neither is the number of null regions limited to one. The number of U-shaped magnets **20** and null regions **78** are limited only by adherence to the rule established by **Equation 3**.

FIG. 13

Referring now to **Fig.2**, **Fig.11B**, **Fig.12** and **Fig.13** there is shown a thirteenth preferred embodiment of the motor **10** comprising a rail **80'** supported by rail mounting posts **76** and having a longitudinal axis **65**. A helical groove **86** having a pre-determined pitch runs around a periphery of the rail **80**.

The thirteenth preferred embodiment also includes three first helical stators **82a, 82b, 82c** (**82**) concentrically surrounding the rail **80'** corresponding to three pairs **32, 32' 32''** of U-shaped magnets **20** mounted on each of five rotors **12**. Preferably, the first helical stators **82** have the same pitch as the pre-determined pitch of the groove **86** and a longitudinal axis generally parallel to the axis **65** of the rail **80'**. A plurality of first stator magnets **11** having a direction of magnetisation aligned with a radial line of each rotor **12** are spaced along each first helical stator **82** with the first stator magnets **11** generating a first magnetic field.

The thirteenth preferred embodiment further includes plurality of second helical stators **82a', 82b', 82c'** (**82'**) alternating with the first helical stators **82'** along the axis **65** of the rail **80'**, and having the pre-determined pitch of the groove **86**. Each second helical stator **82'** has mounted upon it a plurality of second stator magnets **11'** having a direction of magnetisation aligned with a radial line of the rotor **12** and having a direction of magnetisation opposite in direction to the first stator magnets **11** mounted on each of the first helical stators **82**. As a consequence of the second helical stators **82'** being located midway between the first helical stators **82**, a point at about a midpoint between each rotor magnet pair **32, 32', 32"** is apposite to one of the second helical stators **82'** as each rotor **12** rotates about the axis **65** of the rail **80'** and slides along the rail **80'**.

The thirteenth preferred embodiment also includes five rotors **12**, (for clarity, only three are shown), having an axis of rotation **16** generally aligned with the longitudinal axis **65** of the rail **80'**. Each rotor **12** is connected to the rail **80'** by a bearing assembly **84'** so that the rotor **12** is free to rotate about the axis **65** of the rail **80'** and slide along the rail **80'**. Preferably, each rotor **12** includes three pairs **32, 32', 32"** of U-shaped magnets **20** wherein each U-shaped magnet **20** generates a second magnetic field, a portion of which adjacent to a rear **26** of the pair of U-shaped magnets **20** interacts with the first magnetic field of each first stator magnet to cause each rotor **12** to rotate about the axis **65** of the rail **80'**.

The bearing assembly **84'** (shown in detail in **Fig.11B** and **Fig.12**) connects each rotor **12** to the helical groove **86** around the periphery of the rail **80**. The bearing assembly **84'** is similar to the bearing assembly **84'** described in the twelfth preferred embodiment except for the openings in the first bearings **88'** and in the second bearing **90'** which allow the bearing assembly **84'** past the rail mounting posts **76** as the bearing assembly **84'** moves along the rail **80'**.

The thirteenth preferred embodiment may be constructed as either a linear motor or a rotary motor. In the case of the linear motor, the axes of the rail **80'** and of each helical stator **82** are substantially straight. The rail **80'** is supported on the base **18** by rail mounting posts **76** placed at intervals along the rail **80'**. The posts **76** are situated at locations along the rail **80'** at which the rotation of the rotor **12** orients the openings in the first and second bearings **88'**, **90'** to correspond to the mounting posts **76**. Each helical stator **82a, 82b, 82c** is supported on the base by stator mounting posts **75**. The rotors **12** are connected together by a cross-link **94'** which connects the first bearings **88'** of each bearing assembly **84'** to the first bearing **88'** of the bearing assembly **84'** of an adjacent rotor **12**. In this manner, the rotational motion of each rotor assembly **14'** is added together to provide the linear motive power of the linear motor.

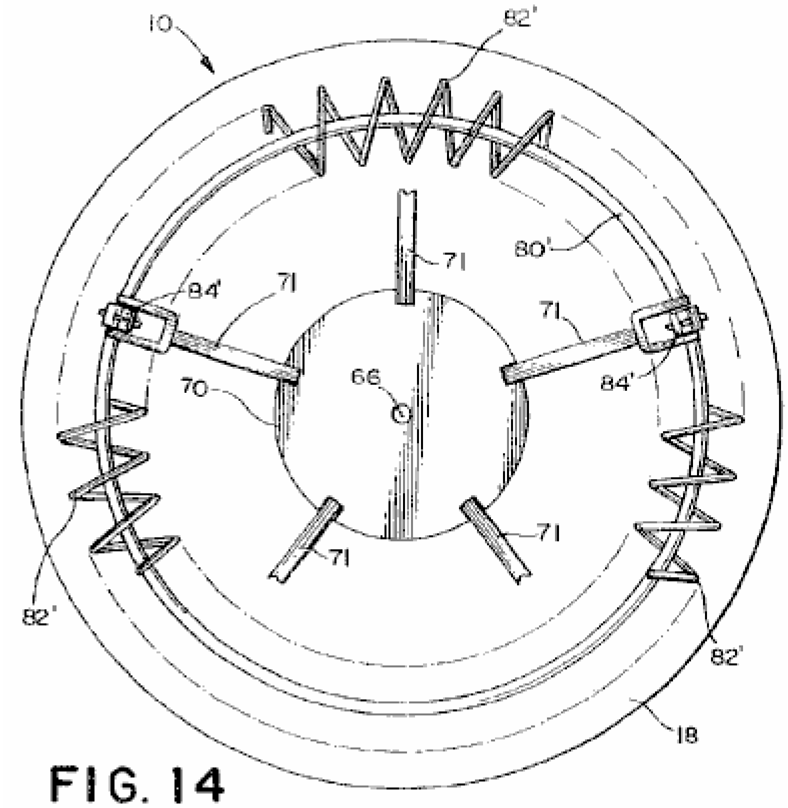

FIG. 14

The thirteenth preferred embodiment may also be constructed as a rotary motor **10** as shown in **Fig.14**. In this case, the axes of the rail **80'** and the helical stators **82** are configured to be circular. The circularly configured motor **10** includes an armature **70** centrally located within the perimeter of the rail **80'**. The armature **70** rotates about an armature axis of rotation **58** connected for rotation within a motor base **18** to which the rail **80'** is also attached by mounting posts **76** (not shown). The pitch of the first and the second helical stators **82**, **82'**, measured at a radius of the rail **80**, preferably equals the predetermined pitch of the helical groove **86**. The armature **70** is fixedly attached to the first bearing **88** (see **Fig.11B**) of each bearing assembly **84'** by an armature strut **71** thereby adding together the rotational motive power of each rotor assembly **14**. In order that the armature strut **71** does not interfere with the first and second helical stators **82**, **82'**, the first and second helical stators **82**, **82'** are made to have an opening toward the armature axis of rotation **58**.

Preferably, each first helical stator **82a, 82b, 82c** has mounted upon it a plurality of first stator magnets **11** with each stator magnet **11** having a direction of magnetisation aligned with a radial line of the rotor **12**. Preferably, the first helical stators **82** are uniformly spaced along the longitudinal axis **65** of the rail **80'** with each first helical stator **82** corresponding to one of the plurality of magnet pairs **32, 32', 32''**. Preferably, each rotor **12** is positioned on the rail **80'** so that one of the rotor magnet pairs **32, 32', 32''** is apposite to one of the corresponding first helical stators **82** as the rotor **12** rotates about the axis **65** of the rail **80** and slides along the rail **80'**. However, as those skilled in the art will appreciate, the rotor magnet pairs **32, 32', 32''** need not be directly apposite to each helical stator **82** as the rotors **12** rotate in order to generate a rotational force.

Alternatively, as will be appreciated by those skilled in the art, the motor **10** can be constructed without the second helical stator **82'**. In the simplest case the motor **10** could comprise only a single first helical stator **82** and a single rotor **12** comprising a single U-shaped magnet **20** generating the second magnetic field. The single rotor **12** is preferably positioned in the groove **86** on the rail **80'** so that the U-shaped rotor magnet **20** is continually apposite to the single first helical stator **82**. Consequently, a portion of the second magnetic field directly adjacent to a rear **26** of the U-shaped magnet **20** interacts with the first magnetic field generated by each first stator magnet **11''** mounted on the helical stator **82** to cause the rotor **12** to rotate about the axis **65** of the rail **80** and to slide along the rail **80'**. Preferably, when only a single first stator **82** set of first stators **82** is used, each first stator magnet **11''** has a direction of magnetisation oriented to be in the plane of the rotor **12** and generally perpendicular to a radial line of the rotor **12**. The north pole and the south pole of the first stator magnet **11''** are preferably spaced apart so that when one pole of the first stator magnet **11** is directly apposite to the rotor magnet **20**, the pole of opposite polarity is equally spaced from the U-shaped magnet **20** of the rotor **12**. As one skilled in the art would appreciate, a plurality of U-shaped rotor magnets **20** and corresponding first helical stators could be used. Further, as those skilled in the art will appreciate, other configurations of the rotor magnet **20** and the stator magnet **11** are possible, all of which rely on the novel attributes of the magnetic field adjacent to the rear **26** of a U-shaped rotor magnet **20**. For example, the previously described stator magnet **11''** perpendicular to the radial line of the rotor **12** could be two separate bar magnets, spaced apart, with the magnetisation of each of the two magnets aligned with a radial line of the rotor and having opposite directions of magnetisation.

FIG. 15A

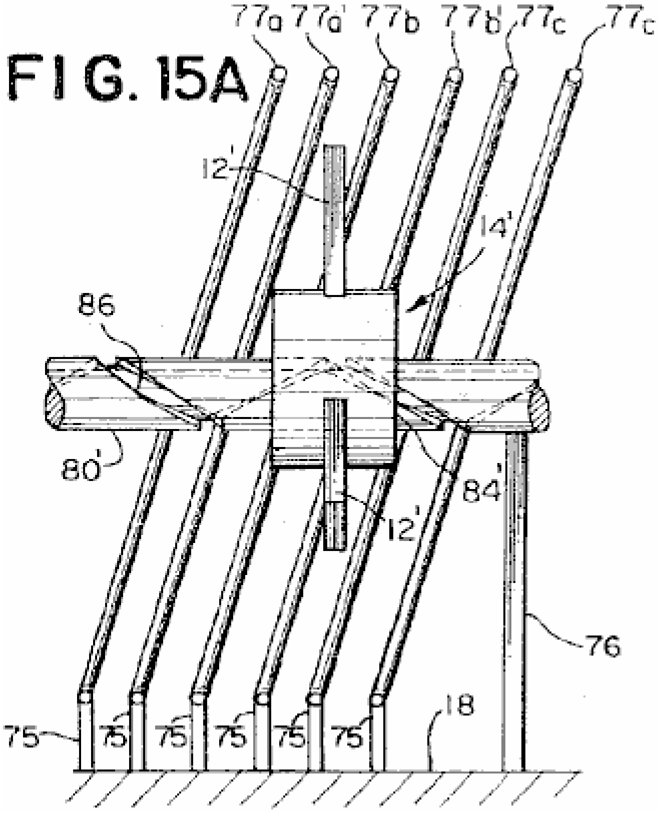

FIG. 15B

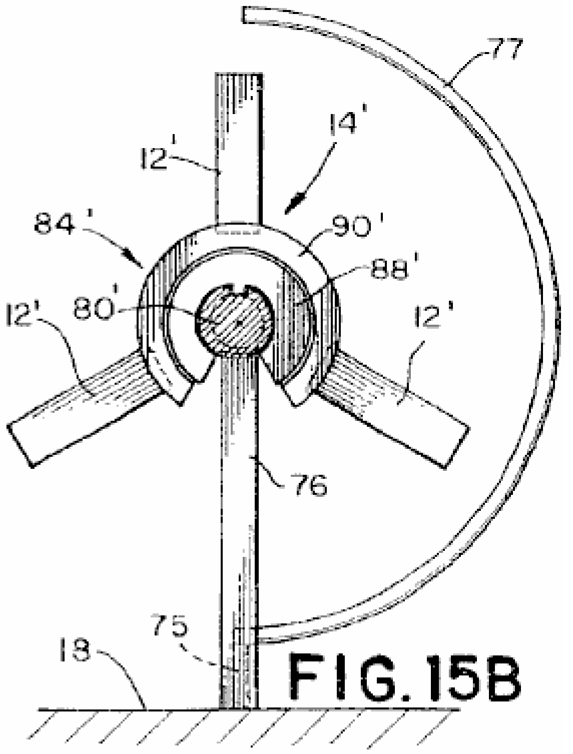

Referring now to **Fig.15A** and **Fig.15B** there is shown a fourteenth preferred embodiment of the motor **10**. The fourteenth embodiment is identical in structure to the thirteenth preferred embodiment except that the stator comprises a plurality of first ribs **77a, 77b, 77c** (**77**) and second ribs **77a', 77b', 77c'** (**77'**) in place of the first and the second helical stators **82, 82'** of the thirteenth embodiment. By substituting ribs **77, 77'** for the helical stators **82, 82'**, the attachment of the armature **70** to the rotors **12** is simplified. As those skilled in the art will appreciate, the length of the ribs **77, 77'** may vary from as little as 45 degrees to up to 265 degrees, with the motive power of the motor **10** being proportional to the length of the ribs.

Preferably, the first and the second ribs **77, 77'** have a pitch and a spacing that conforms to the pre-determined pitch of the rail **80'**. Further the orientation of the first and second stator magnets **11, 11'** and of the U-shaped rotor magnets **20** would be identical to the thirteenth embodiment. Accordingly, the operation of the fourteenth embodiment is identical to that of the thirteenth embodiment and is not repeated here for the sake of brevity.

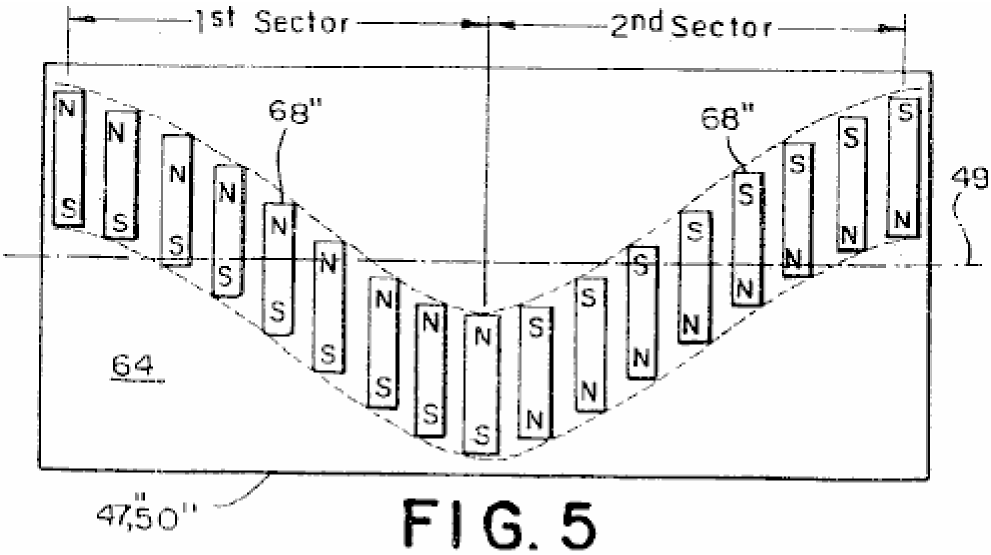

FIG. 5

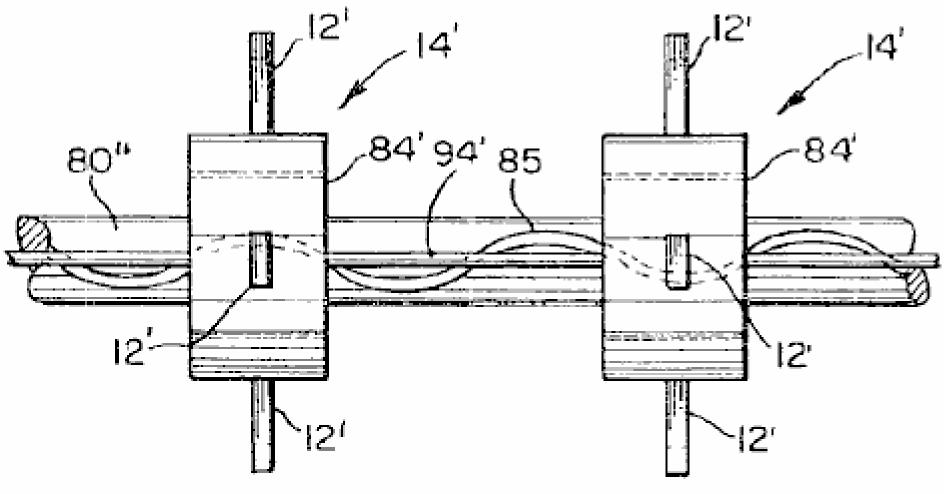

FIG. 16

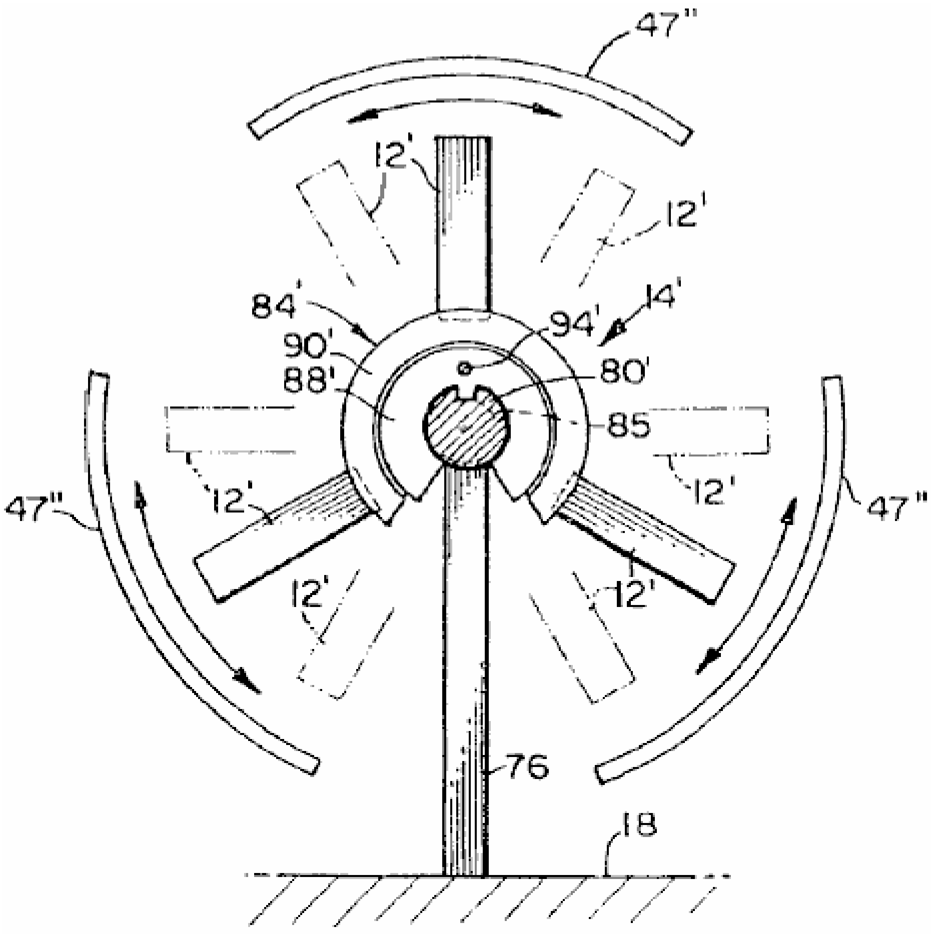

FIG. 17

Referring now to **Fig.5**, **Fig.16** and **Fig.17** there is shown a fifteenth preferred embodiment of the motor **10** comprising a rail **80"** having a longitudinal axis **65** and a generally sinusoidal groove **85** having a pre-determined period running around a periphery of the rail **80"**.

Preferably, the fifteenth preferred embodiment includes three generally identical stators **50"** arrayed in a circular fashion around the rail **80"**. Each stator **50"** has a surface **64** facing the rail **80"** and disposed generally equidistant from and parallel to the axis **65** of the rail **80"**. As shown in **Fig.5** and **Fig.17** each stator **50"** has a generally curved cross-section and a longitudinal line of demarcation **49** perpendicular to the cross-section and located about a midpoint of the surface **64**.

A plurality of stator magnets **68"** are attached to the surface **64** of the stator **50"** generating a first magnetic field. The stator magnets **68"** are displaced on the surface **64** in a sinusoidal pattern around the line of demarcation **49**. The sinusoidal pattern has a pre-determined period and a pre-determined maximum (peak) amplitude along the line of demarcation **49**. In the case where the rail **80"** and the longitudinal line of demarcation **49** of the stator **50"** are in a straight line, the period of the sinusoid is preferably equal to the period of the groove **85** on the rail **80**.

The sinusoidal pattern is also divided into a plurality of first and second alternating sectors with a boundary between the alternating sectors occurring at each maximum (peak) amplitude of the sinusoid. The direction of magnetisation of the stator magnets **68"** is opposite in the first and the second segments so that the direction of the first magnetic field in each first segment is opposite to the direction of the first magnetic field in each second segment. Preferably, the direction of magnetisation of the stator magnets **68"** is generally perpendicular to a radial line of the rotor **12**. Alternatively, the direction of magnetisation of the stator magnets **68"** could be generally aligned with a radial line of the rotor **12**. Further, as will be apparent to those skilled in the art, the first magnetic field need not be formed by a plurality of bar magnets but could be formed from a single magnet so that the first magnetic field would be sinusoidally displaced from the line of demarcation **49** and would alternate in opposite directions between the peaks of the sinusoid. Further, as will be appreciated by those skilled in the art, the displacement of the first magnetic field need not be precisely sinusoidal. For instance the displacement may be in a shape of a sawtooth or in a shape having a portion with constant plus and minus amplitude values, within the spirit and scope of the invention.

Preferably, the fifteenth preferred embodiment includes five rotors **12**, each rotor **12** having an axis **16** aligned with the axis of the rail **80''**. Each rotor **12** is connected to the rail **80''** by a bearing assembly **84'** so that the rotor **12** is free to rotate about the axis of the rail **65** and slide along the rail **80''**. Preferably, each rotor **12** includes three U-shaped magnet pairs **32, 32' 32''**, each pair comprising two U-shaped magnets **20**. Each U-shaped magnet **20** has a rear side and generates a second magnetic field. Each of the U-shaped magnet pairs **32, 32', 32''** is positioned on each rotor **12** so that the rear side **26** of each U-shaped magnet **20** is apposite to the first and the second segments of the sinusoidal pattern as the at least one rotor assembly **14** rotates about the rotor axis **16**, wherein an interaction of a portion of the second magnetic field directly adjacent to the rear **26** of each U-shaped magnet **20** with the first magnetic field of a corresponding stator **50''** causes the at least one rotor **12** to oscillate rotationally about the axis **65** of the rail **80''**. Those skilled in the art will appreciate that it is not necessary to have three pairs of U-shaped magnets **32, 32', 32''**. For instance, the number of U-shaped magnets **20** (or groups of abutted U-shaped magnets) spaced apart around the periphery of the rotor **12** may range from merely a single U-shaped magnet **20**, or may range in number up to a number of magnets limited only by the physical space around the periphery of the rotor **12.** Further the number of abutted U-shaped magnets **20** in a group of magnets **32** may also range from 1 up to a number of magnets limited only by the physical space around the periphery of the rotor **12**. Preferably, the number of stators **50''** equals the number of U-shaped magnet pairs **32, 32', 32''**. However, as will be appreciated by those skilled in the art, the number of stators **50''** is not limited to three but could be any number ranging upward from one, where the number of stators **50''** would preferably equal the number of U-shaped magnet pairs **32, 32', 32''**.

As shown in **Fig.16** the bearing assembly **84'** converts the oscillatory motion of the at least one rotor **12** about the rail to unidirectional linear motion along the rail **80'** by following the sinusoidal groove **85** in the rail **80'** with the boss **92** (shown in **Fig.11B**). A cross-link **94** connects the bearing assembly **84'** of adjacent rotors **12** together, thereby adding together the linear motion of each rotor assembly **14'** along the rail to provide the unidirectional linear motive power. The structure of the bearing assembly **84'** and the cross-link **94** is shown in **Fig.11B** and **Fig.12**, and the operation is identical to the linkage **84'** and the cross-link **94'** described for the twelfth embodiment. Accordingly, a detailed description of the linkage **84'** and the cross-link **94** is not repeated, for the sake of brevity.

In another aspect, the fifteenth preferred embodiment may also be configured in a circular arrangement similar to that of the fourteenth embodiment. In the fifteenth preferred embodiment, the helical stator **82'** shown in **Fig.14** is replaced with one or more curved stators **50''** spaced around the rotors **12**. In this case, the period of the sinusoidal pattern of the stator magnets is adjusted in accordance with the distance of the surface **64** of the respective stator **50''** from the armature axis of rotation **58** in order that the U-shaped magnets **20** on the rotors **12** remain apposite to the first and the second segments, as the rotors **12** slide along the rail **80''**. Accordingly, a description of those elements of circular arrangement of the fifteenth embodiment which are the same as for the linear embodiment are not repeated, for the sake of brevity.

Referring now to **Fig.4**, **Fig.18** and **Fig.19** there is shown a sixteenth preferred embodiment of the motor **10** for providing unidirectional motive power comprising a rail **80''** having a longitudinal axis **65** and a helical groove **86** having a pre-determined pitch, running around a periphery of the rail **80**.

Preferably, the sixteenth preferred embodiment further includes three generally identical stators **50'**, each stator **50'** having a surface **64** disposed generally equidistant from and parallel to the axis **65** of the rail **80**. Each stator **50'** has a longitudinal line of demarcation **49** located about a midpoint of the surface **64**. Preferably, a plurality of stator magnets **68'** are attached to the surface of the stator **50'** generating a first magnetic field. The plurality of stator magnets **68'** have a direction of magnetisation which rotates about a magnetic axis parallel to the line of demarcation **49**. In the case where the rail **80''** and the longitudinal line of demarcation **49** of the stator **50'** are in a straight line, the pitch of the rotation of the stator magnets **68'** is preferably equal to the pre-determined pitch of the helical groove **86** on the rail **80**.

The sixteenth embodiment further includes five rotors **12**, each rotor **12** having an axis of rotation **16** aligned with the axis **65** of the rail **80**. Each rotor **12** is connected to the rail **80** so that the rotor **12** is free to rotate about the axis **65** of the rail **80** and slide along the rail **80**. Each rotor **12** includes three pairs **32, 32', 32''** of U-shaped magnets **20** spaced around the periphery of the rotor **12**, each U-shaped magnet **20** generating a second magnetic field. The U-shaped magnets **20** are positioned on each rotor **12** so that a portion of the second magnetic field directly adjacent to the rear side **26** of the U-shaped magnet **20** interacts with the first magnetic field generated by the plurality of stator magnets **68'** to cause each rotor **12** to rotate about the rotor axis **16**. Those skilled in the art will appreciate that it is not necessary to have exactly three pairs of U-shaped magnets **32, 32', 32''**. For instance, the number of U-shaped magnets **20** (or groups of abutted U-shaped magnets) spaced apart around the periphery of the rotor **12** may range from merely a single U-shaped magnet **20**, or may range in number up to a number of U shaped magnets **20** limited only by the physical space around the periphery of the rotor **12**. Further the number of abutted U-shaped magnets **20** in a group of magnets **32** may also range from 1 up to a number of magnets limited only by the physical space around the periphery of the rotor **12**.

The sixteenth embodiment also includes a bearing assembly 84' connecting each rotor **12** to the helical groove **86**, the bearing assembly **84'** converting the rotary motion of each rotor **12** about the rail **80'** to unidirectional linear motion along the rail **80'**. A cross-link **94** connects the bearing assembly **84'** of adjacent rotors **12** together, thereby adding together the linear motion of each rotor assembly **14'** along the rail **80'** to provide the unidirectional linear motive power. The structure of the bearing assembly **84'** and the cross-link **94** is shown in **Fig.11B** and **Fig.12**, is identical to the bearing assembly **84'** and cross-link **94** described for the twelfth embodiment. Accordingly, a description of the linkage **84** and the cross-link **94** is not repeated, for the sake of brevity.

In another aspect of the sixteenth preferred embodiment the motor **10** may be configured in a circular arrangement similar to that of the fourteenth embodiment, as shown in **Fig.14**, except that the helical stator **82'** shown in **Fig.14** is replaced with one or more stators **50'** spaced around the rotors **12**. In this case, the pitch of the rotation of the plurality of stator magnets **68'** is adjusted in accordance with the distance of the surface **64** of the respective stator **50'** from the armature axis of rotation **58** in order that the U-shaped magnets **20** on the rotors **12** remain aligned with the plurality of stator magnets **68'** as the rotors **12** rotate about the axis **65** of the rail **80'** and slide along the rail **80'**. Accordingly, a description of those elements of the circular arrangement of the sixteenth embodiment which are the same as for the straight line configuration are not repeated, for the sake of brevity.

It will be appreciated by those skilled in the art that changes could be made to the embodiments described above without departing from the broad inventive concept thereof. It is understood, therefore, that this invention is not limited to the particular embodiments disclosed, but it is intended to cover modifications within the spirit and scope of the present invention as defined by the appended claims.

CLAIMS

1. An apparatus (10, 10') characterised by:

at least one rotor (12) having a periphery and a rotor axis (16), the at least one rotor (12) comprising a first rotor magnet (20) producing a first magnetic field, said first rotor magnet being U-shaped and having a north pole (23), a south pole (25) and a rear side (26), the rear side (26) of the first rotor magnet being adjacent to the periphery;

an axle (80) to which the at least one rotor (12) is connected at the rotor axis (16) for rotation of the at least one rotor (12) about the rotor axis (16); and

a stationary stator (48, 51) comprising a generally curved cross-section, said stator (51) having a surface (64) opposing the periphery of the at least one rotor (12), and a longitudinal line of demarcation (49) perpendicular to the cross-section at about a midpoint of the surface, the line of demarcation (49) delineating a first side (52) of the surface from a second side (54) of the surface (64), wherein a plurality of pairs of stator magnets (40, 42) producing a second magnetic field are attached to the surface (64), each pair of stator magnets (40, 42) comprising a first stator magnet (40) having a north pole and a south pole and a direction of magnetisation substantially parallel to the surface (64), and a second stator magnet (42) having a north pole and a south pole and a direction of magnetisation substantially parallel to the surface (64), the first stator magnet (40) being on the first side of the surface (64) with the north pole of the first stator magnet being closest to the line of demarcation (49), the second stator magnet (42) being on the second side (52) of the surface with the south pole of the second stator magnet (42) being closest to the line of demarcation (49), wherein the plurality of pairs of stator magnets (40, 42) are spaced along the line of demarcation (49) so that a first inter-magnet distance measured along the line of demarcation (49) between the north pole of the first stator magnet (40) and the south pole of the second stator (42) magnet of an adjacent pair of stator magnets (40, 42) is about equal to a second inter-magnet distance measured along the line of demarcation between the south pole of the first stator magnet (40) and the north pole of the second stator magnet (42), and wherein the interaction of the first and the second magnetic fields cause the at least one rotor (12) to translate in a predetermined direction along the line of demarcation.

2. The apparatus (10, 10') of claim 1, characterised by the north pole of each first stator magnet (40) and the south pole of each second stator magnet (42) being inclined toward the predetermined direction.

3. The apparatus (10, 10') of claim 1, further characterised by the rotor (12) including a second rotor magnet (22), said second rotor magnet (24) being U-shaped and having a north pole, a south pole and a rear side, the south pole of the second rotor magnet (22) abutting the north pole of the first rotor magnet (26) and the north pole of the second rotor magnet being adjacent to the periphery, and a third rotor magnet (24), said third rotor magnet (24) having a north pole, a south pole and a rear side, the north pole of the third rotor magnet (24) abutting the south pole of the first rotor magnet (26) and the south pole of the third rotor magnet (24) being adjacent to the periphery, said second magnet producing a third magnetic field and third magnet producing a fourth magnetic field.

4. The apparatus (10) of claim 1, characterised by the apparatus further including an armature (70) having an armature axis (58), the at least one rotor (12) being spaced from the armature (70) by an armature strut (71) and connected thereto by the axle (80) for rotation about the rotor axis (16), the at least one rotor (12) configured for rotation in a plane generally aligned with the armature axis (58), wherein the stator (51) is circular-cylindrical, with a stator axis (72) aligned with the armature axis (58).

5. The apparatus (10') of claim 1, further characterised by the stator (48) being linear, the stator (48) oriented so that the surface (64) of the stator (48) is generally parallel to the axle (80), each at least one rotor (12) being connected to the axle (80) by a bearing assembly (84) comprising a pair of first bearings (88) slidably attached to the axle (80), and a second bearing (90) connected to the pair of first bearings (88) for rotation about the first pair of bearings (88), said at least one rotor (12) being fixedly attached to the second bearing (90).

6. The apparatus (10') of claim 5, further characterised by a crosslink (94) which connects together the at least one rotors (12).

7. A apparatus (10, 10') characterised by:

at least one rotor (12) having a periphery, a rotor axis (16) and a thruster axis (34) perpendicular to the rotor axis (16) and intersecting the rotor axis (16), the at least one rotor (12) comprising spaced apart first and second rotor magnets (36, 38) having north and south poles aligned with the thruster axis (34), and a third rotor magnet (20, 20') located between the first and second rotor magnets (34, 38) on an axis generally perpendicular to the thruster axis (34), said first, second and third magnets producing a first magnetic field;

an axle (80) to which the at least one rotor (12) is connected at the rotor axis (16) for rotation of the at least one rotor (12) about the rotor axis (16); and

a stationary stator (48', 51') comprising a generally curved cross-section, said stator (48', 51') having a surface 64 opposing the periphery of the at least one rotor (12), and a longitudinal line of demarcation (49) perpendicular to the cross-section at about a midpoint of the surface (64), the line of demarcation (49) delineating a first side (52) of the surface from a second side (54) of the surface, wherein a plurality of sets of stator magnets (40', 42', 41) producing a second magnetic field are attached to the surface (64), each set of stator magnets (40', 42', 41) comprising a first stator magnet (40') having a north pole and a south pole and a direction of magnetisation substantially perpendicular to the surface (64), a second stator magnet (42') having a north pole and a south pole and a direction of magnetisation substantially perpendicular to the surface (64), and a third stator magnet (41), the third stator magnet (41) being attached to the stator (48', 51') along the line of demarcation (49) midway between the first stator magnet (40') and the second stator magnet (42'), the first stator magnet (40') being on the first side (52) of the surface with the south pole of the first stator magnet (40') being closest surface (64), the second stator magnet (42') being on the second side (54) of the surface (64) with the north pole of the second stator magnet (42') being closest to the surface (64), wherein the plurality of sets of stator magnets (40', 42', 41) are spaced along the line of demarcation (49) so that a first inter-magnet distance measured along the line of demarcation (49) between the north pole of the first stator magnet (40') and the south pole of the second stator magnet (42') of an adjacent pair of stator magnets (40', 42', 41) is about equal to a second inter-magnet distance measured along the line of demarcation (49) between the south pole of the first stator magnet (40') and the north pole of the second stator magnet (42'), wherein the interaction of the first and the second magnetic fields cause the at least one rotor (12) to translate in a predetermined direction along the line of demarcation.

8. The apparatus (10, 10') of claim 7, characterised by the third rotor magnet (20) being a U-shaped magnet and the third stator magnet (41) being a bar magnet.

9. The apparatus (10, 10') of claim 7, characterised by the third rotor magnet (20') being a bar magnet and the third stator magnet (41') being a U-shaped magnet.

10. The apparatus (10) of claim 7, characterised by the apparatus further including an armature (70) having an armature axis (58), the at least one rotor (12) being spaced from the armature (70) by an armature strut (71) and connected thereto by the axle (80) for rotation about the rotor axis (16), the at least one rotor (12) being configured for rotation in a plane generally aligned with the armature axis (58), wherein the stator (51') is circular, with a stator axis (72) aligned with the armature axis (58).

11. The apparatus (10') of claim 7, further characterised by the stator (48') being linear, the stator (48') oriented so that the surface (64) of the stator (48') is generally parallel to the axle (80), each at least one rotor (12) being connected to the axle (80) by a bearing assembly (84) comprising a pair of first bearings (88) slidably attached to the axle (80), and a second bearing (90) connected to the pair of first bearings (88) for rotation about the pair of first bearings (88), said at least one rotor (12) being fixedly attached to the second bearing (90).

12. The apparatus (10') of claim 11, further characterised by a crosslink (94) which connects together the at least one rotors (12).

13. An apparatus (10) for providing motion characterised by:

a stationary, generally circular, stator (50, 50', 50'') having a stator axis (58), an outer surface (64), and a circumferential line of demarcation (49) in a plane perpendicular to the stator axis (58) at about a midpoint of the outer surface (64);

at least one stator magnet (68, 68', 68'') attached to the outer surface (64) of the stator (50, 50', 50''), the at least one stator magnet (68, 68', 68'') being arranged in a generally circular arrangement about the stator axis (58);
an armature (70) attached to the stator (50, 50'', 50'') for rotation therewith, the armature (70) having an axis parallel to the stator axis (58);

at least one rotor (12) including at least one rotor magnet (20), the at least one rotor (12) being spaced from the armature (70) by an armature strut (71) and connected thereto by an axle (80) for rotation about a rotor axis (16), the at least one rotor (12) being configured for rotation in a plane generally aligned with the stator axis (58); and

a driving linkage assembly (53, 55, 62) connecting the at least one rotor to the stator, the linkage assembly (53, 55, 62) configured to cause the armature (70) to rotate about the stator axis (58) when the at least one rotor (12) rotates about the rotor axis (16).

14. The apparatus according to claim 13 wherein a direction of magnetisation of the at least one stator magnet (68) is generally perpendicular to a radial line of the at least one rotor (12).

15. The apparatus according to claim 13 wherein a direction of magnetisation of the at least one stator magnet (68) is generally aligned with a radial line of the at least one rotor (12).

16. The apparatus according to claim 13 wherein the at least one rotor magnet (20) comprises a U-shaped magnet.

17. The apparatus according to claim 13 wherein the at least one rotor magnet (20) comprises a bar magnet and the at least one stator magnet (68) is a U-shaped magnet.

18. The apparatus according to claim 13, the at least one stator magnet (68') having a direction of magnetisation which rotates about the circumferential line of demarcation (49) with a predetermined periodicity.

19. The apparatus according to claim 13, the at least one stator magnet (68'') having a direction of magnetisation in a plane of the stator (50'') and which is displaced in a sinusoidal pattern from the line of demarcation (49), the sinusoidal pattern having a pre-determined period and a pre-determined maximum amplitude and divided into a plurality of alternating first and second sectors with a boundary between the alternating first and second sectors occurring at peak amplitudes of the sinusoid, the direction of magnetisation of the at least one magnet (68'') being opposite in direction in the first and the second segments.

HOWARD JOHNSON: PERMANENT MAGNET MOTOR

Patent US 4,151,431 **24th April 1979** **Inventor: Howard R. Johnson**

PERMANENT MAGNET MOTOR

This is a re-worded extract from this Patent. It describes a motor powered solely by permanent magnets and which it is claimed can power an electrical generator.

ABSTRACT

The invention is directed to the method of utilising the unpaired electron spins in ferromagnetic and other materials as a source of magnetic fields for producing power without any electron flow as occurs in normal conductors, and to permanent magnet motors for utilising this method to produce a power source. In the practice of the invention the unpaired electron spins occurring within permanent magnets are utilised to produce a motive power source solely through the superconducting characteristics of a permanent magnet, and the magnetic flux created by the magnets is controlled and concentrated to orientate the magnetic forces generated in such a manner to produce useful continuous work, such as the displacement of a rotor with respect to a stator. The timing and orientation of magnetic forces at the rotor and stator components produced by the permanent magnets is accomplished by the proper geometrical relationship of these components.

BACKGROUND OF THE INVENTION:

Conventional electric motors employ magnetic forces to produce either rotational or linear motion. Electric motors operate on the principal that when a conductor which carries a current is located in a magnetic field, a magnetic force is exerted upon it. Normally, in a conventional electric motor, the rotor, or stator, or both, are so wired that magnetic fields created by electromagnets use attraction, repulsion, or both types of magnetic forces, to impose a force upon the armature causing rotation, or linear displacement of the armature. Conventional electric motors may employ permanent magnets either in the armature or stator components, but to date they require the creation of an electromagnetic field to act upon the permanent magnets. Also, switching gear is needed to control the energising of the electromagnets and the orientation of the magnetic fields producing the motive power.

It is my belief that the full potential of magnetic forces existing in permanent magnets has not been recognised or utilised because of incomplete information and theory with respect to atomic motion occurring within a permanent magnet. It is my belief that a presently unnamed atomic particle is associated with the electron movement of a superconducting electromagnet and the loss-less flow of currents in permanent magnets. The unpaired electron flow is similar in both situations. This small particle is believed to be opposite in charge to an electron and to be located at right angles to the moving electron. This particle must be very small to penetrate all known elements in their various states as well as their known compounds (unless they have unpaired electrons which capture these particles as they endeavour to pass through).

The electrons in ferrous materials differ from those found in most elements in that they are unpaired, and being unpaired they spin around the nucleus in such a way that they respond to magnetic fields as well as creating a magnetic field themselves. If they were paired, their magnetic fields would cancel out. However, being unpaired they create a measurable magnetic field if their spins are orientated in one direction. The spins are at right angles to their magnetic fields.

In niobium superconductors, at a critical state, the magnetic lines of force cease to be at right angles. This change must be due to establishing the required conditions for unpaired electronic spins instead of electron flow in the conductor, and the fact that very powerful electromagnets can be formed with superconductors illustrates the tremendous advantage of producing the magnetic field by unpaired electron spins rather than conventional electron flow. In a superconducting metal, wherein the electrical resistance becomes greater in the metal than the proton resistance, the flow turns to electron spins and the positive particles flow parallel in the metal in the manner occurring in a permanent magnet where a powerful flow of magnetic positive particles or magnetic flux causes the unpaired electrons to spin at right angles. Under cryogenic superconduction conditions the freezing of the crystals in place makes it possible for the spins to continue, and in a permanent magnet the grain orientation of the magnetised material allows these spins, permitting them to continue and causing the flux to flow parallel to the metal. In a superconductor, at first the electron is flowing and the positive particle is spinning; later, when critical, the reverse occurs, i.e., the electron is spinning and the positive particle is flowing at right angles. These positive particles will thread or work their way through the electron spins present in the metal.

In a sense, a permanent magnet may be considered a room-temperature superconductor. It is a superconductor because the electron flow does not cease, and this electron flow can be made to do work through the magnetic field which it creates. Previously, this source of power has not been used because it was not possible to modify the electron flow to accomplish the switching functions of the magnetic field. Such switching functions are common in a conventional electric motor where electrical current is employed to align the much greater electron current in the iron pole pieces and concentrate the magnetic field at the proper places to give the thrust necessary to move the motor armature. In a conventional electric motor, switching is accomplished by the use of brushes, commutators, alternating current, or other means.

In order to accomplish the switching function in a permanent magnet motor, it is necessary to shield the magnetic leakage so that it will not appear as too great a loss factor at the wrong places. The best method to accomplish this is to concentrate the magnetic flux in the place where it will be the most effective. Timing and switching can be achieved in a permanent magnet motor by concentrating the flux and using the proper geometry of the motor rotor and stator to make most effective use of the magnetic fields. By the proper combination of materials, geometry and magnetic concentration, it is possible to achieve a mechanical advantage of high ratio, greater than 100 to 1, capable of producing continuous motive force.

To my knowledge, previous work done with permanent magnets, and motive devices utilising permanent magnets, have not achieved the result desired in the practice of the inventive concept, and it is with the proper combination of materials, geometry and magnetic concentration that the presence of the magnetic spins within a permanent magnet may be utilised as a motive force.

SUMMARY OF THE INVENTION:

It is an object of the invention to utilise the magnetic spinning phenomenon of unpaired electrons occurring in ferromagnetic material to produce the movement of a mass in a unidirectional manner so as to permit a motor to be driven solely by the magnetic forces occurring within permanent magnets. Both linear and rotational types of motor may be produced. It is an object of the invention to provide the proper combination of materials, geometry and magnetic concentration to power a motor. Whether the motor is a linear type or a rotary type, in each instance the "stator" may consist of several permanent magnets fixed relative to each other, to create a track. This track is linear for a linear motor and circular for a rotary motor. An armature magnet is carefully positioned above this track so that an air gap exists between it and the track. The length of the armature magnet is defined by poles of opposite polarity, and the longer axis of the armature magnet is pointed in the direction of its movement.

The stator magnets are mounted so that all the same poles face the armature magnet. The armature magnet has poles which are both attracted to and repelled by the adjacent pole of the stator magnets, so both attractive and repulsive forces act upon the armature magnet to make it move.

The continuing motive force which acts on the armature magnet is caused by the relationship of the length of the armature magnet to the width and spacing of the stator magnets. This ratio of magnet and magnet spacings, and with an acceptable air gap spacing between the stator and armature magnets, produces a continuous force which causes the movement of the armature magnet.

In the practice of the invention, movement of the armature magnet relative to the stator magnets results from a combination of attractive and repulsive forces between the stator and armature magnets. By concentrating the magnetic fields of the stator and armature magnets the motive force imposed upon the armature magnet is intensified, and in the disclosed embodiments, the means for achieving this magnetic field concentration are shown.

This method comprises of a plate of high magnetic field permeability placed behind one side of the stator magnets and solidly engaged with them. The magnetic field of the armature magnet may be concentrated and directionally oriented by bowing the armature magnet, and the magnetic field may further be concentrated by shaping the pole ends of the armature magnet to concentrate the magnet field at a relatively limited surface at the armature magnet pole ends.

Preferably, several armature magnets are used and these are staggered relative to each other in the direction their movement. Such an offsetting or staggering of the armature magnets distributes the impulses of force imposed upon the armature magnets and results in a smoother application of forces to the armature magnet producing a smoother and more uniform movement of the armature component.

In the rotary embodiment of the permanent magnet motor of the invention the stator magnets are arranged in a circle, and the armature magnets rotate about the stator magnets. A mechanism is shown which can move the armature relative to the stator and this controls the magnitude of the magnetic forces, altering the speed of rotation of the motor.

BRIEF DESCRIPTION OF THE DRAWINGS

The objects and advantages of the invention mentioned earlier, will be appreciated from the following description and accompanying drawings:

Fig. 1 is a schematic view of electron flow in a superconductor indicating the unpaired electron spins,
Fig. 2 is a cross-sectional view of a superconductor under a critical state illustrating the electron spins,
Fig. 3 is a view of a permanent magnet illustrating the flux movement through it,
Fig. 4 is a cross-sectional view illustrating the diameter of the magnet of Fig.3,
Fig. 5 is an elevational representation of a linear motor embodiment of the permanent magnet motor of the invention illustrating one position of the armature magnet relative to the stator magnets, and indicating the magnetic forces imposed upon the armature magnet,
Fig. 6 is a view similar to Fig.5 illustrating displacement of the armature magnet relative to the stator magnets, and the influence of magnetic forces thereon at this location,
Fig. 7 is a further elevational view similar to Fig.5 and Fig.6 illustrating further displacement of the armature magnet to the left, and the influence of the magnetic forces thereon,
Fig. 8 is a top plan view of a linear embodiment of the inventive concept illustrating a pair of armature magnets in linked relationship disposed above the stator magnets,
Fig. 9 is a diametrical, elevational, sectional view of a rotary motor embodiment in accord with the invention as taken along section IX-IX of Fig.10, and
Fig. 10 is an elevational view of the rotary motor embodiment as taken along X-X of Fig.9.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In order to better understand the theory of the inventive concept, reference is made to **Figs. 1 through 4**. In **Fig.1** a superconductor 1 is illustrated having a positive particle flow as represented by arrow **2**, the unpaired electrons of the ferrous conductor **1** spin at right angles to the proton flow in the conductor as represented by the spiral line and arrow **3**. In accord with the theory of the invention the spinning of the ferrous unpaired electrons results from the atomic structure of ferrous materials and this spinning atomic particle is believed to be opposite in charge and located at right angles to the moving electrons. It is assumed to be very small in size capable of penetrating other elements and their compounds unless they have unpaired electrons which capture these particles as they endeavour to pass through.

The lack of electrical resistance of conductors at a critical superconductor state has long been recognised, and superconductors have been utilised to produce very high magnetic flux density electromagnets. **Fig.2** represents a cross section of a critical superconductor and the electron spins are indicated by the arrows **3**. A permanent magnet may be considered a superconductor as the electron flow therein does not cease, and is without resistance, and unpaired electric spinning particles exist which, in the practice of the invention, are utilised to produce motor force. **Fig.3** illustrates a horseshoe shaped permanent magnet at **4** and the magnetic flux through it is indicated by arrows **5**, the magnetic flow being from the south pole to the north pole and through the magnetic material. The accumulated electron spins occurring about the diameter of the magnet **5** are represented at **6** in

Fig.4, and the spinning electron particles spin at right angles in the iron as the flux travels through the magnet material.

By utilising the electron spinning theory of ferrous material electrons, it is possible with the proper ferromagnetic materials, geometry and magnetic concentration to utilise the spinning electrons to produce a motive force in a continuous direction, thereby resulting in a motor capable of doing work.

It is appreciated that the embodiments of motors utilising the concepts of the invention may take many forms, and in the illustrated forms the basic relationships of components are illustrated in order to disclose the inventive concepts and principles. The relationships of the plurality of magnets defining the stator 10 are best appreciated from **Figs. 5 through 8**. The stator magnets **12** are preferably of a rectangular configuration, **Fig.8**, and so magnetised that the poles exist at the large surfaces of the magnets, as will be appreciated from the N (North) and S (South) designations. The stator magnets include side edges **14** and **16** and end edges **18**. The stator magnets are mounted upon a supporting plate **20**, which is preferably of a metal having a high permeability to magnetic fields and magnetic flux such as that available under the trademark Netic CoNetic sold by Perfection Mica Company of Chicago, Illinois. Thus, the plate **20** will be disposed toward the south pole of the stator magnets **12**, and preferably in direct engagement therewith, although a bonding material may be interposed between the magnets and the plate in order to accurately locate and fix the magnets on the plate, and position the stator magnets with respect to each other.

Preferably, the spacing between the stator magnets **12** slightly differs between adjacent stator magnets as such a variation in spacing varies the forces being imposed upon the armature magnet at its ends, at any given time, and thus results in a smoother movement of the armature magnet relative to the stator magnets. Thus, the stator magnets so positioned relative to each other define a track **22** having a longitudinal direction left to right as viewed in **Figs. 5 through 8**.

In **Figs. 5 through 7** only a single armature magnet **24** is disclosed, while in **Fig.8** a pair of armature magnets are shown. For purposes of understanding the concepts of the invention the description herein will be limited to the use of single armature magnet as shown in **Figs. 5 through 7**.

The armature magnet is of an elongated configuration wherein the length extends from left to right, **Fig.5**, and may be of a rectangular transverse cross-sectional shape. For magnetic field concentrating and orientation purposes the magnet **24** is formed in an arcuate bowed configuration as defined by concave surfaces **26** and convex surfaces **28**, and the poles are defined at the ends of the magnet as will be appreciated from **Fig.5**. For further magnetic field concentrating purposes the ends of the armature magnet are shaped by bevelled surfaces **30** to minimise the cross sectional area at the magnet ends **32**, and the magnetic flux existing between the poles of the armature magnet are as indicated by the light dotted lines. In like manner the magnetic fields of **6** the stator magnets **12** are indicated by the light dotted lines.

The armature magnet **24** is maintained in a spaced relationship above the stator track **22**. This spacing may be accomplished by mounting the armature magnet upon a slide, guide or track located above the stator magnets, or the armature magnet could be mounted upon a wheeled vehicle carriage or slide supported upon a non-magnetic surface or guideway disposed between the stator magnets and the armature magnet. To clarify the illustration, the means for supporting the armature magnet **24** is not illustrated and such means form no part of invention, and it is to be understood that the means supporting the armature magnet prevents the armature magnet from moving away from the stator magnets, or moving closer thereto, but permits free movement of the armature magnet to the left or right in a direction parallel to the track **22** defined by the stator magnets.

It will be noted that the length of the armature magnet **24** is slightly greater than the width of two of the stator magnets **12** and the spacing between them. The magnetic forces acting upon the armature magnet when in the position of **Fig.5** will be repulsion forces **34** due to the proximity of like polarity forces and attraction forces at **36** because of the opposite polarity of the south pole of the armature magnet, and the north pole field of the sector magnets. The relative strength of this force is represented by the thickness of the force line.

The resultant of the force vectors imposed upon the armature magnet as shown in **Fig.5** produce a primary force vector **38** toward the left, **Fig.5**, displacing the armature magnet **24** toward the left. In **Fig.6** the magnetic forces acting upon the armature magnet are represented by the same reference numerals as in **Fig.5**. While the forces **34** constitute repulsion forces tending to move the north pole of the armature magnet away from the stator magnets, the attraction forces imposed upon the south pole of the armature magnet and some of the repulsion forces, tend to move the armature magnet further to the left, and as the resultant force **38** continues to be toward the left the armature magnet continues to be forced to the left. **Fig.7** represents further displacement of the armature magnet **24** to the left with respect to the position of **Fig.6**, and the magnetic forces acting thereon are represented by the same reference numerals as in **Fig.5** and **Fig.6**, and the stator magnet will continue to move to the left, and such movement continues the length of the track **22** defined by the stator magnets **12**.

Upon the armature magnet being reversed such that the north pole is positioned at the right as viewed in **Fig.5**, and the south pole is positioned at the left, the direction of movement of the armature magnet relative to the stator magnets is toward the right, and the theory of movement is identical to that described above.

In **Fig.8** a plurality of armature magnets **40** and **42** are illustrated which are connected by links **44**. The armature magnets are of a shape and configuration identical to that of the embodiment of **Fig.5**, but the magnets are staggered with respect to each other in the direction of magnet movement, i.e., the direction of the track **22** defined by the stator magnets **12**. By so staggering a plurality of armature magnets a smoother movement of the interconnected armature magnets is produced as compared when using a single armature magnet as there is variation in the forces acting upon each armature magnet as it moves above the track **22** due to the change in magnetic forces imposed thereon. The use of several armature magnets tends to "smooth out" the application of forces imposed upon linked armature magnets, resulting in a smoother movement of the armature magnet assembly. Of course, any number of armature magnets may be interconnected, limited only by the width of the stator magnet track **22**.

In **Fig.9** and **Fig.10** a rotary embodiment embracing the inventive concepts is illustrated. In this embodiment the principle of operation is identical to that described above, but the orientation of the stator and armature magnets is such that rotation of the armature magnets is produced about an axis, rather than a linear movement being achieved.

In **Fig.9** and **Fig.10** a base is represented at **46** serving as a support for a stator member **48**. The stator member **48** is made of a non-magnetic material, such as synthetic plastic, aluminium, or the like. The stator includes a cylindrical surface **50** having an axis, and a threaded bore **52** is concentrically defined in the stator. The stator includes an annular groove **54** receiving an annular sleeve **56** of high magnetic field permeability material such as Netic Co-Netic and a plurality of stator magnets **58** are affixed upon the sleeve **56** in spaced circumferential relationship as will be apparent in **Fig.10**. Preferably, the stator magnets **58** are formed with converging radial sides as to be of a wedge configuration having a curved inner surface engaging sleeve **56**, and a convex pole surface **60**.

The armature **62**, in the illustrated embodiment, is of a dished configuration having a radial web portion, and an axially extending portion **64**. The armature **62** is formed of a non-magnetic material, and an annular belt receiving groove **66** is defined therein for receiving a belt for transmitting power from the armature to a generator, or other power consuming device. Three armature magnets **68** are mounted on the armature portion **64**, and such magnets are of a configuration similar to the armature magnet configuration of **Figs. 5 through 7**.

The magnets **68** are staggered with respect to each other in a circumferential direction wherein the magnets are not placed exactly 120 degrees apart but instead, a slight angular staggering of the armature magnets is desirable to "smooth out" the magnetic forces being imposed upon the armature as a result of the magnetic forces being simultaneously imposed upon each of the armature magnets. The staggering of the armature magnets **68** in a circumferential direction produces the same effect as the staggering of the armature magnets **40** and **42** as shown in **Fig.8**.

The armature **62** is mounted upon a threaded shaft **70** by anti-friction bearings **72**, and the shaft **70** is threaded into the stator threaded bore **52**, and may be rotated by the knob **74**. In this manner rotation of the knob **74**, and shaft **70**, axially displaces the armature **62** with respect to the stator magnets **58**, and such axial displacement will very the magnitude of the magnetic forces imposed upon the armature magnets **68** by the stator magnets thereby controlling the speed of rotation of the armature. As will be noted from **Figs. 4 to 7, 9 and 10**, an air gap exists between the armature magnets and the stator magnets and the dimension of this spacing, effects the magnitude of the forces imposed upon the armature magnet or magnets. If the distance between the armature magnets and the stator magnets is reduced the forces imposed upon the armature magnets by the stator magnets are increased, and the resultant force **8** vector tending to displace the armature magnets in their path of movement increases. However, the decreasing of the spacing between the armature and stator magnets creates a "pulsation" in the movement of the armature magnets which is objectionable, but can be, to some extent, minimised by using a plurality of armature magnets. Increasing the distance between the armature and stator magnets reduces the pulsation tendency of the armature magnet, but also reduces the magnitude of the magnetic forces imposed upon the armature magnets. Thus, the most effective spacing between the armature and stator magnets is that spacing which produces the maximum force vector in the direction of armature magnet movement, with a minimum creation of objectionable pulsation.

In the disclosed embodiments the high permeability plate **20** and sleeve **56** are disclosed for concentrating the magnetic field of the stator magnets, and the armature magnets are bowed and have shaped ends for magnetic field concentration purposes. While such magnetic field concentration means result in higher forces imposed upon the armature magnets for given magnet intensities, it is not intended that the inventive concepts be limited to the use of such magnetic field concentrating means.

As will be appreciated from the above description of the invention, the movement of the armature magnet or magnets results from the described relationship of components. The length of the armature magnets as related to the width of the stator magnets and spacing between them, the dimension of the air gap and the configuration of the magnetic field, combined, produce the desired result and motion. The inventive concepts may be practised even though these relationships may be varied within limits not yet defined and the invention is intended to encompass all dimensional relationships which achieve the desired goal of armature movement. By way of example, with respect to **Figs. to 7**, the following dimensions were used in an operating prototype:

The length of armature magnet **24** is 3.125", the stator magnets **12** are 1" wide, .25" thick and 4" long and grain oriented. The air gap between the poles of the armature magnet and the stator magnets is approximately 1.5" and the spacing between the stator magnets is approximately .5" inch.

In effect, the stator magnets define a magnetic field track of a single polarity transversely interrupted at spaced locations by the magnetic fields produced by the lines of force existing between the poles of the stator magnets and the unidirectional force exerted on the armature magnet is a result of the repulsion and attraction forces existing as the armature magnet traverses this magnetic field track.

It is to be understood that the inventive concept embraces an arrangement wherein the armature magnet component is stationary and the stator assembly is supported for movement and constitutes the moving component, and other variations of the inventive concept will be apparent to those skilled in the art without departing from the scope thereof. As used herein the term "track" is intended to include both linear and circular arrangements of the static magnets, and the "direction" or "length" of the track is that direction parallel or concentric to the intended direction of armature magnet movement.

CLAIMS

1. A permanent magnet motor comprising, in combination, a stator track defining a track direction and having first and second sides and composed of a plurality of track permanent magnets each having first and second poles of opposite polarity, said magnets being disposed in side-by-side relationship having a spacing between adjacent magnets and like poles defining said track sides, an elongated armature permanent magnet located on one of said track sides for relative movement thereto and in spaced relationship to said track side wherein an air gap exists between said armature magnet and said track magnets, said armature magnet having first and second poles of opposite polarity located at the opposite ends of said armature magnet deeming the length thereof, the length of said armature magnet being disposed in a direction in general alignment with the direction of said track, the spacing of said armature magnet poles from said track associated side and the length of said armature magnet as related to the width and spacing of said track magnets in the direction of said track being such as to impose a continuous force on said armature magnet in said general direction of said track.

2. In a permanent magnet motor as in claim 1 wherein the spacing between said poles of said armature and the adjacent stator track side are substantially equal.

3. In a permanent magnet motor as in claim 1 wherein the spacing between adjacent track magnets varies.

4. In a permanent magnet motor as in claim 1 wherein a plurality of armature magnets are disposed on a common side of said stator track, said armature magnets being mechanically interconnected.

5. In a permanent magnet motor as in claim 4 wherein said armature magnets are staggered with respect to each other in the direction of said track.

6. In a permanent magnet motor as in claim 1 wherein magnetic field concentrating means are associated with said track magnets.

7. In a permanent magnet motor as in claim 6 wherein said field concentrating means comprises a sheet of magnetic material of high field permeability engaging side and pole of said track opposite to that side and pole disposed toward said armature magnet.

8. In a permanent magnet as in claim 1 wherein said armature magnet is of an arcuate configuration in its longitudinal direction bowed toward said track, said armature magnet having ends shaped to concentrate the magnetic field at said ends.

9. In a permanent magnet motor as in claim 1 wherein said stator track is of a generally linear configuration, and means supporting said armature magnet relative to said track for generally linear movement of said armature magnet.

10. In a permanent magnet motor as in claim 1 wherein said stator track magnets define a circle having an axis, an armature rotatably mounted with respect to said track and concentric and coaxial thereto, said armature magnet being mounted upon said armature.

11. In a permanent magnet motor as in claim 10, means axially adjusting said armature relative to said track whereby the axial relationship of said armature magnet and said stator magnets may be varied to adjust the rate of rotation of said armature.

12. In a permanent magnet motor as in claim 10 wherein a plurality of armature magnets are mounted on said armature.

13. In a permanent magnet motor as in claim 12 wherein said armature magnets are circumferentially non-uniformly spaced on said armature.

14. A permanent magnet motor comprising, in combination, a stator comprising a plurality of circumferentially spaced stator permanent magnets having poles of opposite polarity, said magnets being arranged to substantially define a circle having an axis, the poles of said magnets facing in a radial direction with respect to said axis and poles of the same polarity facing away from said axis and the poles of opposite polarity facing toward said axis, an armature mounted for rotation about said axis and disposed adjacent said stator, at least one armature permanent magnet having poles of opposite polarity mounted on said armature and in radial spaced relationship to said circle of stator magnets, said armature magnet poles extending in the circumferential direction of armature rotation, the spacing of said armature magnet poles from said stator magnets and the circumferential length of said armature magnet and the spacing of said stator magnets being such as to impose a continuing circumferential force on said armature magnet to rotate said armature.

15. In a permanent magnet motor as in claim 14 wherein a plurality of armature magnets are mounted upon said armature.

16. In a permanent magnet motor as in claim 14 wherein said armature magnets are asymmetrically circumferentially spaced on said armature.

17. In a permanent magnet motor as in claim 14 wherein the poles of said armature magnet are shaped to concentrate the magnetic field thereof.

18. In a permanent magnet motor as in claim 14, magnetic field concentrating means associated with said stator magnets concentrating the magnetic fields thereof at the spacings between adjacent stator magnets.

19. In a permanent magnet motor as in claim 18 wherein said magnet field concentrating means comprises an annular ring of high magnetic field permeability material concentric with said axis and in substantial engagement with poles of like polarity of said stator magnets.

20. In a permanent magnet motor as in claim 14 wherein said armature magnet is of an arcuate bowed configuration in the direction of said poles thereof defining a concave side and a convex side, said concave side being disposed toward said axis, and said poles of said armature magnet being shaped to concentrate the magnetic field between said poles thereof.

21. In a permanent magnet motor as in claim 14, means for axially displacing said stator and armature relative to each other to adjust the axial alignment of said stator and armature magnets.

22. The method of producing a unidirectional motive force by permanent magnets using a plurality of spaced stator permanent magnets having opposite polarity poles defining a track having a predetermined direction, and an armature magnet having a length defined by poles of opposite polarity movably mounted for movement relative to the track in the direction thereof, and of a predetermined length determined by the width and dimensions of said stator magnets comprising forming a magnetic field track by said stator magnets having a magnetic field of common polarity interrupted at spaced locations in a direction transverse to the direction of said magnetic field track by magnetic fields created by magnetic lines of force existing between the poles of the stator magnets and positioning the armature magnet in spaced relation to said magnetic field track longitudinally related to the direction of the magnetic field track such a distance that the repulsion and attraction forces imposed on the armature magnet by said magnetic field track imposes a continuing unidirectional force on the armature magnet in the direction of the magnetic field track.

23. The method of producing a unidirectional motive force as in claim 22 including concentrating the magnetic fields created by magnetic lines of force between the poles of the stator magnets.

24. The method of producing a unidirectional motive force as in claim 22 including concentrating the magnetic field existing between the poles of the armature magnet.

25. The method of producing a unidirectional motive force as in claim 22 including concentrating the magnetic fields created by magnetic lines of force between the poles of the stator magnets and concentrating the magnetic field existing between the poles of the armature magnet.

26. The method of producing a motive force by permanent magnets wherein the unpaired electron spinning particles existing within a permanent magnet are utilised for producing a motive force comprising forming a stator magnetic field track by means of at least one permanent magnet, producing an armature magnetic field by means of a permanent magnet and shaping and locating said magnetic fields in such a manner as to produce relative continuous unidirectional motion between said stator and armature field producing magnets.

27. The method of producing a motive force by permanent magnets as in claim 26 wherein said stator magnetic field is substantially of a single polarity.

28. The method of producing a motive force by permanent magnets as in claim 26 including concentrating the magnetic field of said stator field track and armature magnetic field.

HAROLD EWING: THE CAROUSEL ELECTRIC GENERATOR

US Patent 5,625,241 29th April 1997 Inventor: Harold E. Ewing et al.

CAROUSEL ELECTRIC GENERATOR

This is a reworded excerpt form this patent which shows a compact, self-powered, combined permanent magnet motor and electrical generator. There is a little extra information at the end of this document.

ABSTRACT

A permanent magnet generator or motor having stationary coils positioned in a circle, a rotor on which are mounted permanent magnets grouped in sectors and positioned to move adjacent to the coils, and a carousel carrying corresponding groups of permanent magnets through the centres of the coils, the carousel movies with the rotor by virtue of its being magnetically coupled to it.

BACKGROUND OF THE INVENTION

There are numerous applications for small electric generators in ratings of a few kilowatts or less. Examples include electric power sources for emergency lighting in commercial and residential buildings, power sources for remote locations such as mountain cabins, and portable power sources for motor homes, pleasure boats, etc.

In all of these applications, system reliability is a primary concern. Because the power system is likely to sit idle for long periods of time without the benefit of periodic maintenance, and because the owner-operator is often inexperienced in the maintenance and operation of such equipment, the desired level of reliability can only be achieved through system simplicity and the elimination of such components as batteries or other secondary power sources which are commonly employed for generator field excitation.

Another important feature for such generating equipment is miniaturisation particularly in the case of portable equipment. It is important to be able to produce the required level of power in a relatively small generator.

Both of these requirements are addressed in the present invention through a novel adaptation of the permanent magnet generator or magneto in a design that lends itself to high frequency operation as a means for maximising power output per unit volume.

DESCRIPTION OF THE PRIOR ART

Permanent magnet generators or magnetos have been employed widely for many years. Early applications of such generators include the supply of electric current for spark plugs in automobiles and aeroplanes. Early telephones used magnetos to obtain electrical energy for ringing. The Model T Ford automobile also used magnetos to power its electric lights.

The present invention differs from prior art magnetos in terms of its novel physical structure in which a multiplicity of permanent magnets and electrical windings are arranged in a fashion which permits high-speed/high-frequency operation as a means for meeting the miniaturisation requirement. In addition, the design is enhanced through the use of a rotating carousel which carries a multiplicity of field source magnets through the centres of the stationary electric windings in which the generated voltage is thereby induced.

SUMMARY OF THE INVENTION

In accordance with the invention claimed, an improved permanent magnet electric generator is provided with a capability for delivering a relatively high level of output power from a small and compact structure. The incorporation of a rotating carousel for the transport of the primary field magnets through the electrical windings in which induction occurs enhances field strength in the locations critical to generation.

It is, therefore, one object of this invention to provide an improved permanent magnet generator or magneto for the generation of electrical power. Another object of this invention is to provide in such a generator a relatively high level of electrical power from a small and compact structure. A further object of this invention is to achieve such a high level of electrical power by virtue of the high rotational speed and high frequency operation of which the generator of the invention is capable.

A further object of this invention is to provide such a high frequency capability through the use of a novel field structure in which the primary permanent magnets are carried through the centres of the induction windings of the generator by a rotating carousel.

A still further object of this invention is to provide a means for driving the rotating carousel without the aid of mechanical coupling but rather by virtue of magnetic coupling between other mechanically driven magnets and those mounted on the carousel.

A still further object of this invention is to provide an enhanced capability for high speed/high frequency operation through the use of an air bearing as a support for the rotating carousel.

Yet another object of this invention is to provide in such an improved generator a sufficiently high magnetic field density in the locations critical to voltage generation without resort to the use of laminations or other media to channel the magnetic field.

Further objects an advantages of the invention will become apparent as the following description proceeds and the features of novelty which characterise the invention will be pointed out with particularity in the claims annexed to and forming a part of this specification.

BRIEF DESCRIPTION OF THE DRAWINGS

DESCRIPTION OF THE PREFERRED EMBODIMENT

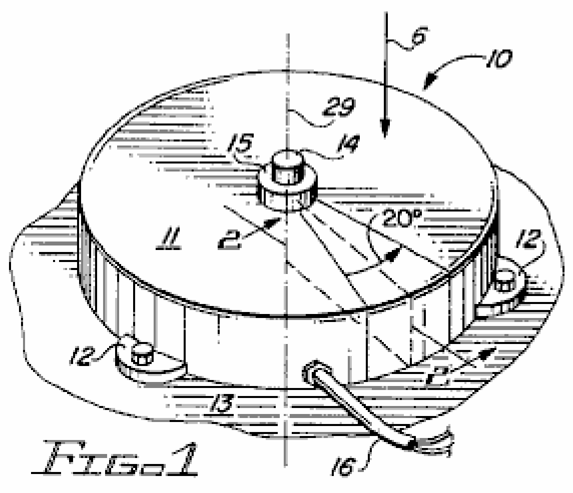

FIG.1

Referring more particularly to the drawings by characters of reference, **Fig.1** shows the external proportions of a carousel electric generator **10** of the invention. As shown in **Fig.1**, generator **10** is enclosed by a housing **11** with mounting feet **12** suitable for securing the generator to a flat surface **13**. The surface **13** is preferably horizontal, as shown in **Fig.1**.

Housing **11** has the proportions of a short cylinder. A drive shaft **14** extends axially from housing **11** through a bearing **15**. The electrical output of the generator is brought out through a cable **16**.

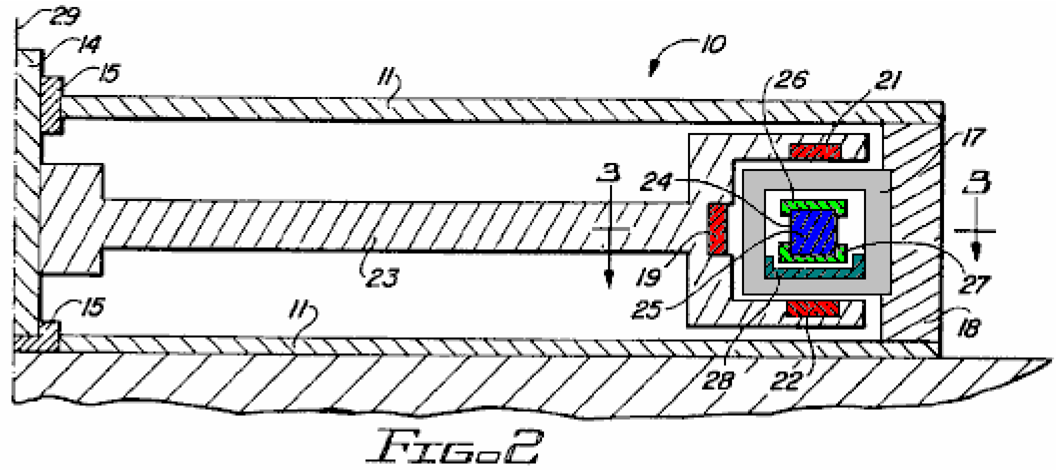

FIG.2

The cross-sectional view of **Fig.2** shows the active elements incorporated in one twenty degree sector of the stator and in one twenty degree sector of the rotor.

In the first implementation of the invention, there are eighteen identical stator sectors, each incorporating a winding or coil **17** wound about a rectangular coil frame or bobbin. Coil **17** is held by a stator frame **18** which may also serve as an outer wall of frame **11**.

The rotor is also divided into eighteen sectors, nine of which incorporate three permanent magnets each, including an inboard rotor magnet **19**, an upper rotor magnet **21** and a lower rotor magnet **22**. All three of these magnets have their south poles facing coil **17**, and all three are mounted directly on rotor frame **23** which is secured directly to drive shaft **14**.

The other nine sectors of the rotor are empty, i.e. they are not populated with magnets. The unpopulated sectors are alternated with the populated sectors so that adjacent populated sectors are separated by an unpopulated sector as shown in **Fig.3** and **Fig.6**.

With reference again to **Fig.2**, generator **10** also incorporates a carousel **24**. The carousel comprises nine pairs of carousel magnets **25** clamped between upper and lower retainer rings **26** and **27**, respectively. The lower retainer ring **27** rests inside an air bearing channel **28** which is secured to stator **18** inside the bobbin of coil **17**. Air passages (not shown) admit air into the space between the lower surface of ring **27** and the upper or inside surface of channel **28**. This arrangement comprises an air bearing which permits carousel **24** to rotate freely within the coils **17** about rotational axis **29** of rotor frame **23**.

Carousel **24** is also divided into **18** twenty-degree sectors, including nine populated sectors interspersed with nine unpopulated sectors in an alternating sequence. Each of the nine populated sectors incorporates a pair of carousel magnets as described in the preceding paragraph.

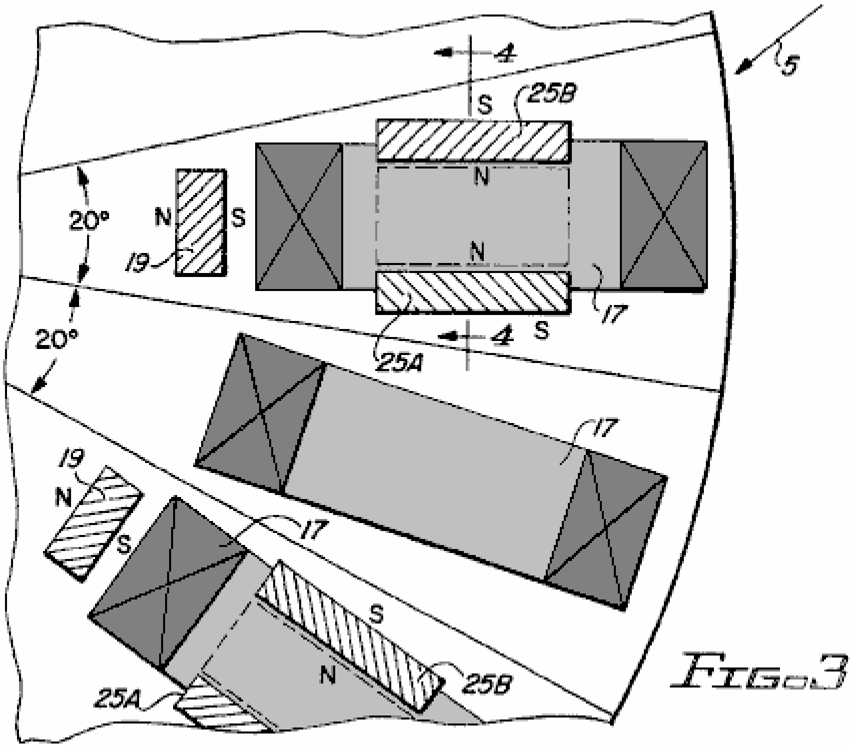

Fig. 3

The geometrical relationship between the rotor magnets, the carousel magnets and the coils, is further clarified by **Fig.3**, **Fig.4** and **Fig.5**. In each of the three figures, the centre of each populated rotor sector is shown aligned with the centre of a coil **17**. Each populated carousel sector, which is magnetically locked into position with a populated rotor sector, is thus also aligned with a coil **17**.

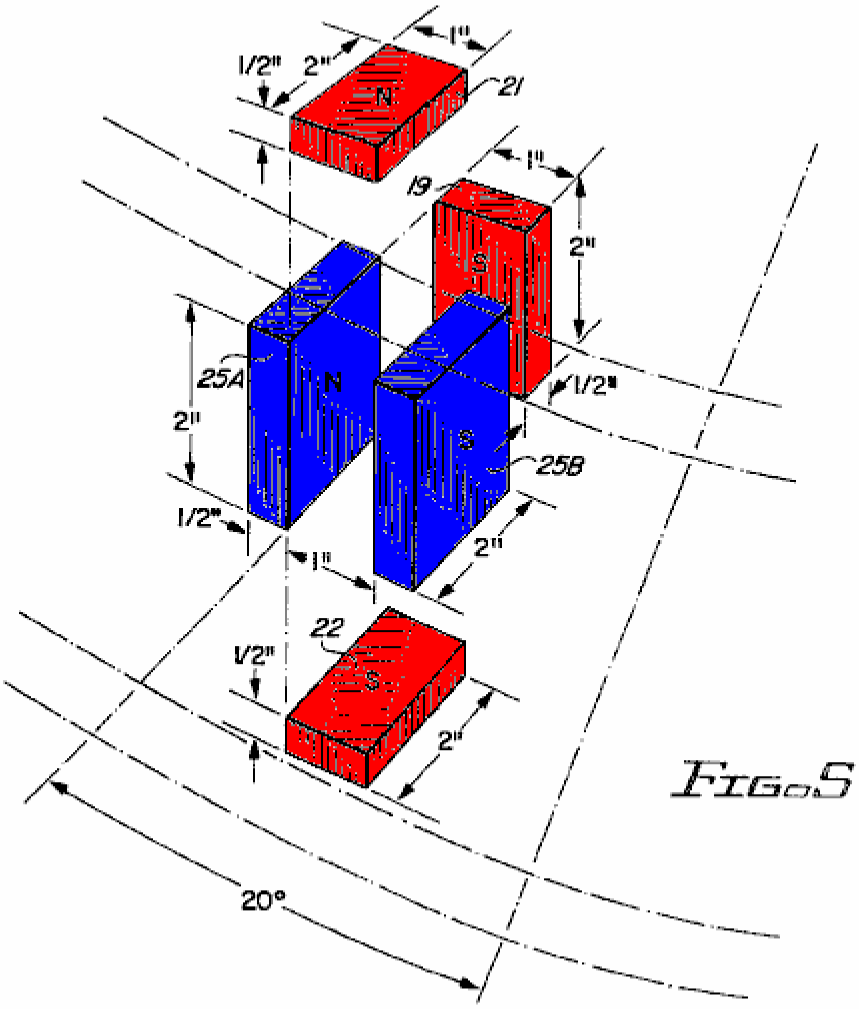

FIG.5

In an early implementation of the invention, the dimensions and spacings of the rotor magnets **19**, **21** and **22** and carousel magnets, **25A** and **25B** of carousel magnet pairs **25** were as shown in **Fig.5**. Each of the rotor magnets **19**, **21** and **22** measured one inch by two inches by one-half inch with north and south poles at opposite one-inch by two-inch faces. Each of the carousel magnets **25A** and **25B** measured two inches by two inches by one-half inch with north and south poles at opposite two-inch by two-inch faces. The magnets were obtained from Magnet Sales and Manufacturing, Culver City, Calif. The carousel magnets were part No.35NE2812832; the rotor magnets were custom parts of equivalent strength (MMF) but half the cross section of the carousel magnets.

Coil supports and other stationary members located within magnetic field patterns are fabricated from Delrin or Teflon plastic or equivalent materials. The use of aluminium or other metals introduce eddy current losses and in some cases excessive friction.

As shown in **Fig.5**, carousel magnets **25A** and **25B** stand on edge, parallel with each other, their north poles facing each other, and spaced one inch apart. When viewed from directly above the carousel magnets, the space between the two magnets **25A** and **25B** appears as a one-inch by two-inch rectangle. When the carousel magnet pair **25** is perfectly locked into position magnetically, upper rotor magnet **21** is directly above this one-inch by two-inch rectangle, lower rotor magnet **22** is directly below it, and their one-inch by two-inch faces are directly aligned with it, the south poles of the two magnets **21** and **22** facing each other.

In like manner, when viewed from the axis of rotation of generator **10**, the space between carousel magnets **25A** and **25B** again appears as a one-inch by two-inch rectangle, and this rectangle is aligned with the one-inch by two-inch face of magnet **19**, the south pole of magnet **19** facing the carousel magnet pair **25**.

Rotor magnets **19**, **21** and **22** are positioned as near as possible to carousel magnets **25A** and **25B** while still allowing passage for coil **17** over and around the carousel magnets and through the space between the carousel magnets and the rotor magnets.

In an electric generator, the voltage induced in the generator windings is proportional to the product of the number of turns in the winding and the rate of change of flux linkages that is produced as the winding is rotated through the magnetic field. An examination of magnetic field patterns is therefore essential to an understanding of generator operation.

In generator **10**, magnetic flux emanating from the north poles of carousel magnets **25A** and **25B** pass through the rotor magnets and then return to the south poles of the carousel magnets. The total flux field is thus driven by the combined MMF (magnetomotive force) of the carousel and field magnets while the flux patterns are determined by the orientation of the rotor and carousel magnets.

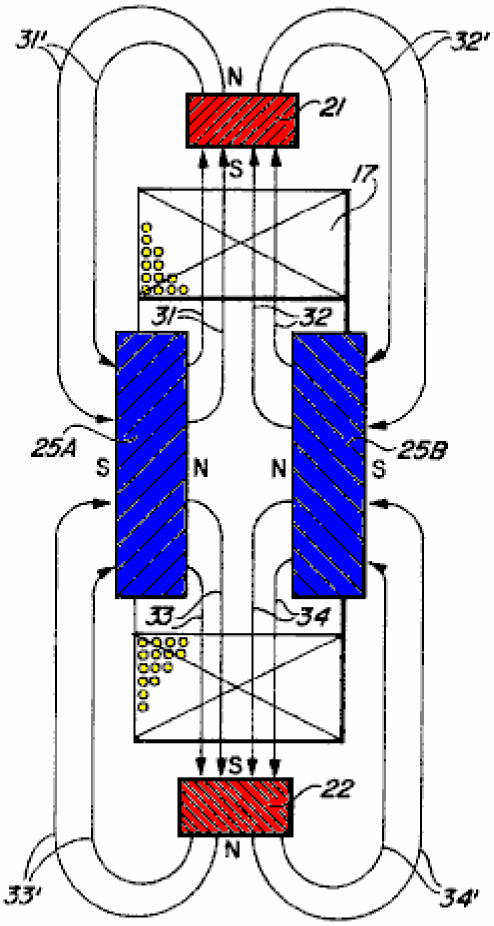

FIG. 4

The flux pattern between carousel magnets **25A** and **25B** and the upper and lower rotor magnets **21** and **22** is illustrated in **Fig.4**. Magnetic flux lines **31** from the north pole of carousel magnet **25A** extend to the south pole of upper rotor magnet **21**, pass through magnet **21** and return as lines **31'** to the south pole of magnet **25A**. Lines **33**, also from the north pole of magnet **25A** extend to the south pole of lower rotor magnet **22**, pass through magnet **22** and return to the south pole of magnet **25A** as lines **33'**. Similarly, lines **32** and **34** from the north pole of magnet **25B** pass through magnets **21** and **22**, respectively, and return as lines **32'** and **34'** to the south pole of magnet **25B**. Flux linkages produced in coil **17** by lines emanating from carousel magnet **25A** are of opposite sense from those emanating from carousel magnet **25B**. Because induced voltage is a function of the rate of change in net flux linkages, it is important to recognise this difference in sense.

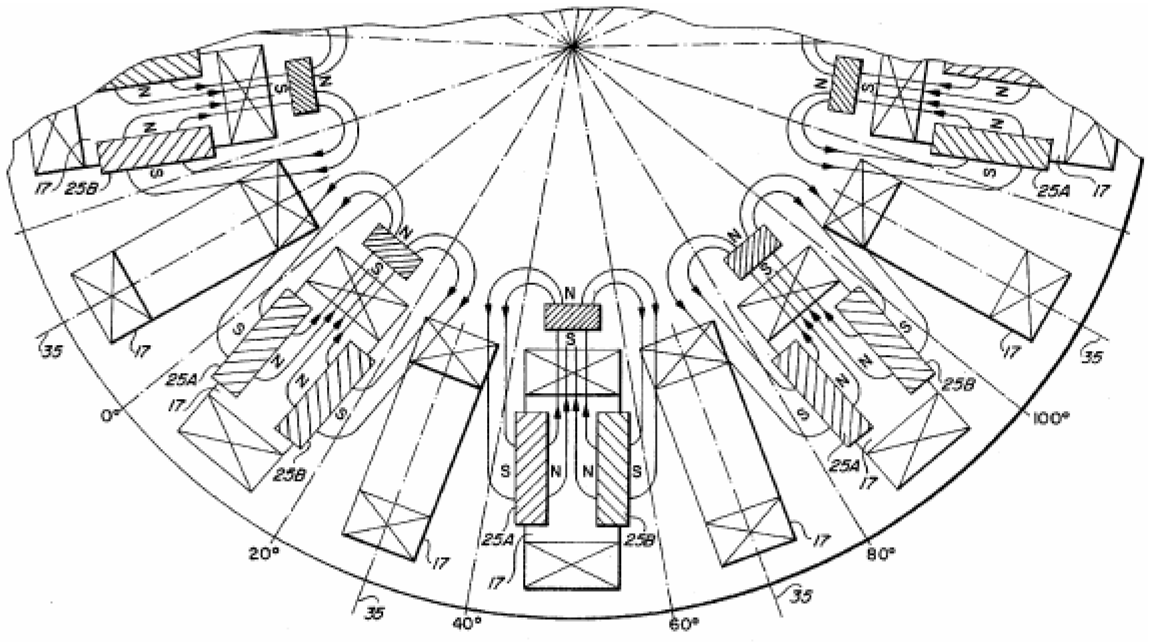

Fig.6

Fig.6 shows a similar flux pattern for flux between carousel magnets **25A** and **25B** and inboard rotor magnet **19**. Again the lines emanating from carousel magnet **25A** and passing through rotor magnet **19** produce flux linkages in coil **17** that are opposite in sense from those produced by lines from magnet **25B**.

The arrangement of the carousel magnets with the north poles facing each other tends to confine and channel the flux into the desired path. This arrangement replaces the function of magnetic yokes or laminations of more conventional generators.

The flux linkages produced by magnets **25A** and **25B** are opposite in sense regardless of the rotational position of coil **17** including the case where coil **17** is aligned with the carousel and rotor magnets as well as for the same coils when they are aligned with an unpopulated rotor sector.

Taking into account the flux patterns of **Fig.4** and **Fig.6** and recognising the opposing sense conditions just described, net flux linkages for a given coil **17** are deduced as shown in **Fig.7**.

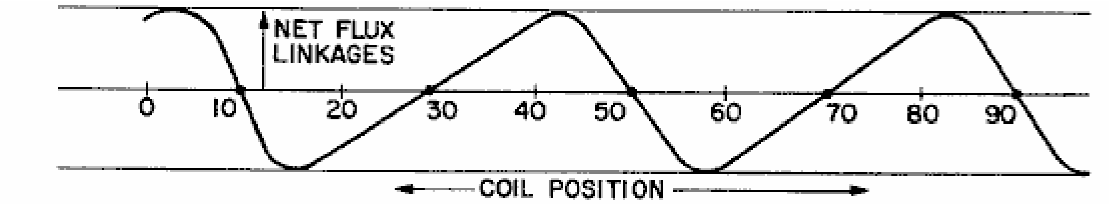

Fig.7

In **Fig.7**, net flux linkages (coil-turns x lines) are plotted as a function of coil position in degrees. Coil position is here defined as the position of the centreline **35** of coil **17** relative to the angular scale shown in degrees in **Fig.6**. (Note that the coil is stationary and the scale is fixed to the rotor. As the rotor turns in a clockwise direction, the relative position of coil **17** progresses from zero to ten to twenty degrees etc.).

At a relative coil position of ten degrees, the coil is centred between magnets **25A** and **25B**. Assuming symmetrical flux patterns for the two magnets, the flux linkages from one magnet exactly cancel the flux linkages from the other so that net flux linkages are zero. As the relative coil position moves to the right, linkages from magnet **25A** decrease and those from magnet **25B** increase so that net flux linkages build up from zero and passes through a maximum negative value at some point between ten and twenty degrees. After reaching the negative maximum, flux linkages decrease, passing through zero at 30 degrees (where coil **17** is at the centre of an unpopulated rotor sector) and then rising to a positive maximum at some point just beyond 60 degrees. This cyclic variation repeats as the coil is subjected successively to fields from populated and unpopulated rotor sectors.

As the rotor is driven rotationally, net flux linkages for all eighteen coils are altered at a rate that is determined by the flux pattern just described in combination with the rotational velocity of the rotor. Instantaneous voltage induced in coil **17** is a function of the slope of the curve shown in **Fig.7** and rotor velocity, and voltage polarity changes as the slope of the curve alternates between positive and negative.

It is important to note here that a coil positioned at ten degrees is exposed to a negative slope while the adjacent coil is exposed to a positive slope. The polarities of the voltages induced in the two adjacent coils are therefore opposite. For series or parallel connections of odd and even-numbered coils, this polarity discrepancy can be corrected by installing the odd and even numbered coils oppositely (odds rotated end for end relative to evens) or by reversing start and finish connections of odd relative to even numbered coils. Either of these measures will render all coil voltages additive as needed for series or parallel connections. Unless the field patterns for populated and unpopulated sectors are very nearly symmetrical, however, the voltages induced in odd and even numbered coils will have different waveforms. This difference will not be corrected by the coil reversals or reverse connections discussed in the previous paragraph. Unless the voltage waveforms are very nearly the same, circulating currents will flow between even and odd-numbered coils. These circulating currents will reduce generator efficiency.

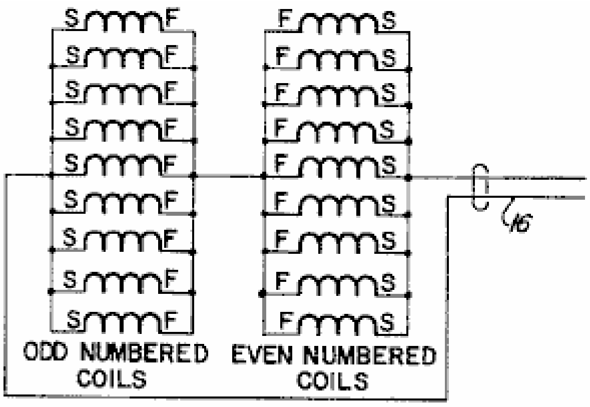

Fig.8

To prevent such circulating currents and the attendant loss in operating efficiency for non symmetrical field patterns and unmatched voltage waveforms, the series-parallel connections of **Fig.8** may be employed in a high-current, low-voltage configuration of the generator. If the eighteen coils are numbered in sequence from one to eighteen according to position about the stator, all even-numbered coils are connected in parallel, all odd-numbered coils are connected in parallel, and the two parallel coil groups are connected in series as shown with reversed polarity for one group so that voltages will be in phase relative to output cable **16**.

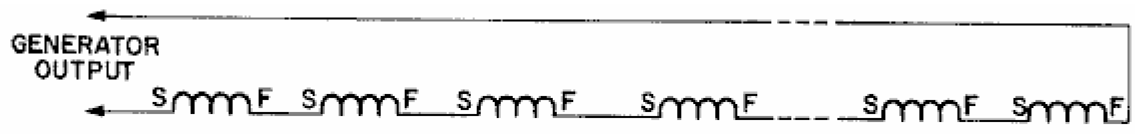

Fig.9

For a low-current, high voltage configuration, the series connection of all coils may be employed as shown in **Fig.9**. In this case, it is only necessary to correct the polarity difference between even and odd numbered coils. As mentioned earlier, this can be accomplished by means of opposite start and finish connections for odd and even coils or by installing alternate coils reversed, end for end.

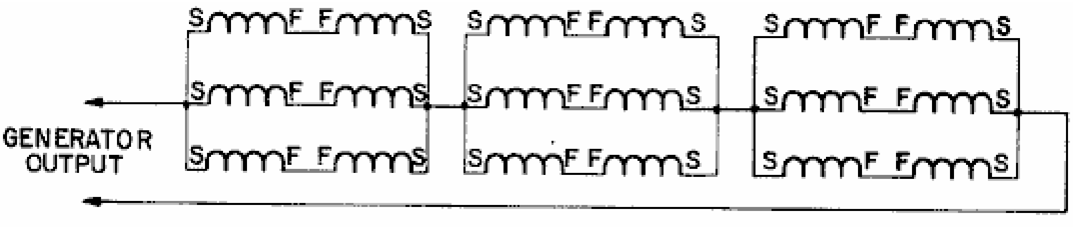

Fig.10

For intermediate current and voltage configurations, various series-parallel connections may be employed. **Fig.10**, for example, shows three groups of six coils each connected in series. Circulating currents will be avoided so long as even-numbered coils are not connected in parallel with odd-numbered coils. Parallel connection of series-connected odd/even pairs as shown is permissible because the waveforms of the series pairs should be very neatly matched.

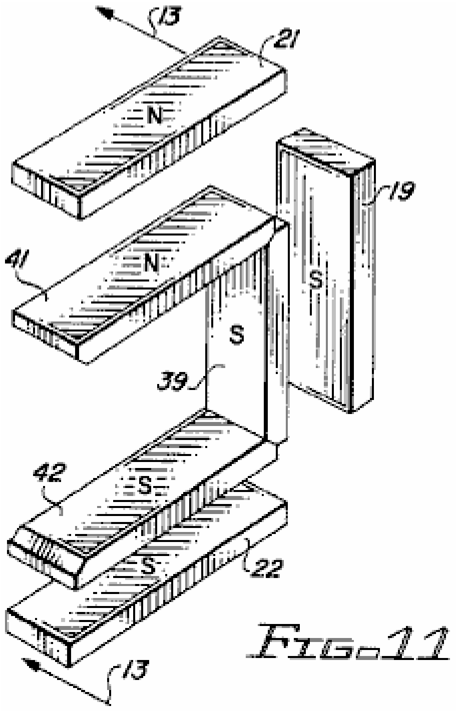

FIG. 11

In another embodiment of the invention, the two large (two-inch by two-inch) carousel magnets are replaced by three smaller magnets as shown in **Fig.11**, **Fig.12** and **Fig.13**. The three carousel magnets comprise an inboard carousel magnet **39**, an upper carousel magnet **41** and a lower carousel magnet **42** arranged in a U-shaped configuration that matches the U-shaped configuration of the rotor magnets **19**, **21** and **22**. As in the case of the first embodiment, the rotor and carousel magnets are present only in alternate sectors of the generator.

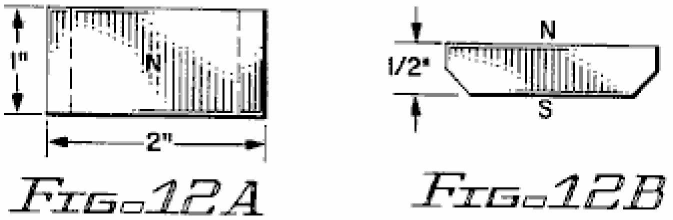

FIG. 12A FIG. 12B

The ends of the carousel magnets are bevelled to permit a more compact arrangement of the three magnets. As shown in **Fig.12**, each magnet measures one inch by two inches by one half inch thick. The south pole occupies the bevelled one-inch by two-inch face and the north pole is at the opposite face.

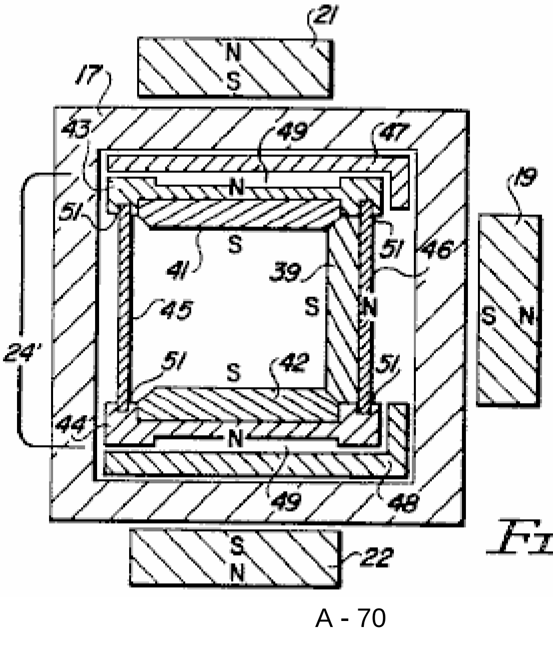

FIG. 13

The modified carousel structure **24'** as shown in **Fig.13** comprises an upper carousel bearing plate **43**, a lower carousel bearing plate **44**, an outer cylindrical wall **45** and an inner cylindrical wall **46**. The upper and lower bearing plates **43** and **44** mate with the upper and lower bearing members **47** and **48**, respectively, which are stationary and secured inside the forms of the coils **17**. Bearing plates **43** and **44** are shaped to provide air channels **49** which serve as air bearings for rotational support of the carousel **24'**. The bearing plates are also slotted to receive the upper and lower edges **51** of cylindrical walls **45** and **46**.

The modified carousel structure **24'** offers a number of advantages over the first embodiment. The matched magnet configuration of the carousel and the rotor provides tighter and more secure coupling between the carousel and the rotor. The smaller carousel magnets also provide a significant reduction in carousel weight. This was found beneficial relative to the smooth and efficient rotational support of the carousel.

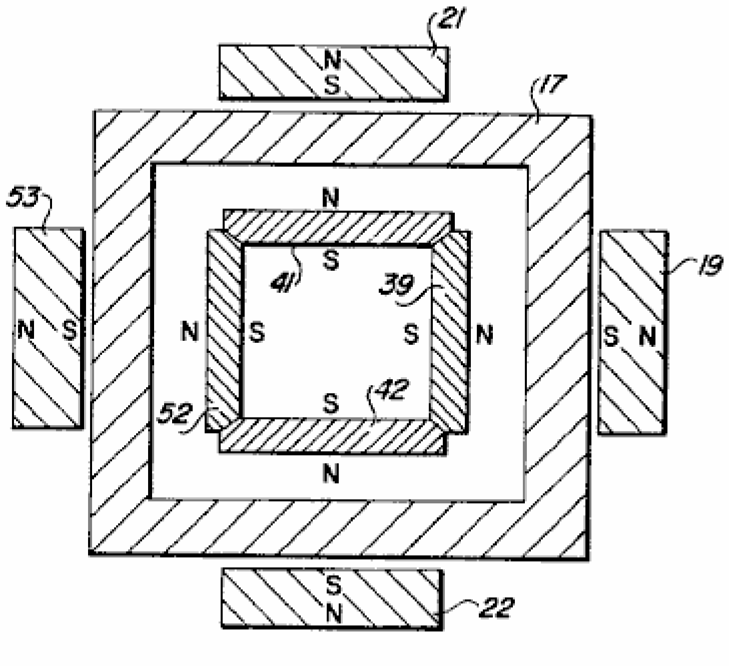

Fig.14

The modification of the carousel structure as described in the foregoing paragraphs can be taken one step further with the addition of a fourth carousel magnet **52** at each station as shown in **Fig.14**. The four carousel magnets **39**, **41**, **42** and **52** now form a square frame with each of the magnet faces (north poles) facing a corresponding inside face of the coil **17**. Carousel magnets for this modification may again be as shown in **Fig.12**. An additional rotor magnet **53** may also be added as shown, in alignment with carousel magnet **52**. These additional modifications further enhance the field pattern and the degree of coupling between the rotor and the carousel.

The carousel electric generator of the invention is particularly well suited to high speed, high frequency operation where the high speed compensates for lower flux densities than might be achieved with a magnetic medium for routing the field through the generator coils. For many applications, such as emergency lighting, the high frequency is also advantageous. Fluorescent lighting, for example, is more efficient in terms of lumens per watt and the ballasts are smaller at high frequencies.

While the present invention has been directed toward the provision of a compact generator for specialised generator applications, it is also possible to operate the device as a motor by applying an appropriate alternating voltage source to cable **16** and coupling drive shaft **14** to a load.

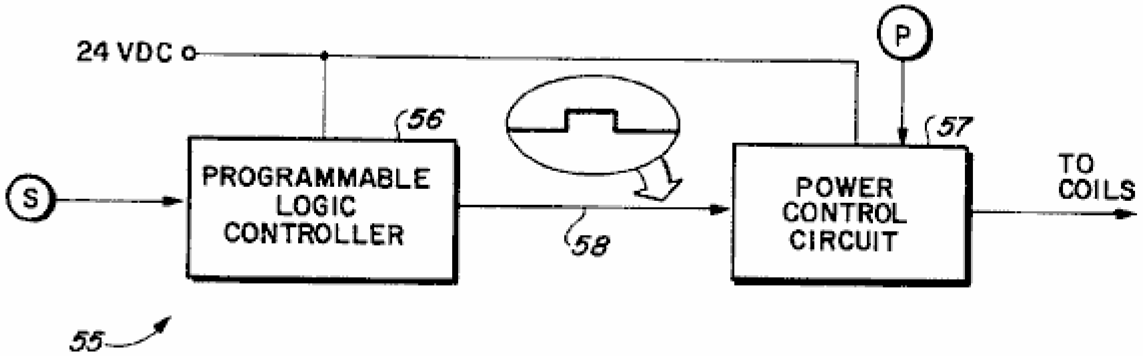

Fig.15

It is also possible to operate the device of the invention as a motor using a pulsed direct-current power source. A control system **55** for providing such operation is illustrated in **Fig.15**. Incorporated in the control system **55** are a rotor position sensor **S**, a programmable logic controller **56**, a power control circuit **57** and a potentiometer **P**.

Based on signals received from sensor **S**, controller **56** determines the appropriate timing for coil excitation to assure maximum torque and smooth operation. This entails the determination of the optimum positions of the rotor and the carousel at the initiation and at the termination of coil excitation. For smooth operation and maximum torque, the force developed by the interacting fields of the magnets and the excited coils should be unidirectional to the maximum possible extent.

Typically, the coil is excited for only 17.5 degrees or less during each 40 degrees of rotor rotation.

The output signal **58** of controller **56** is a binary signal (high or low) that is interpreted as an ON and OFF command for coil excitation.

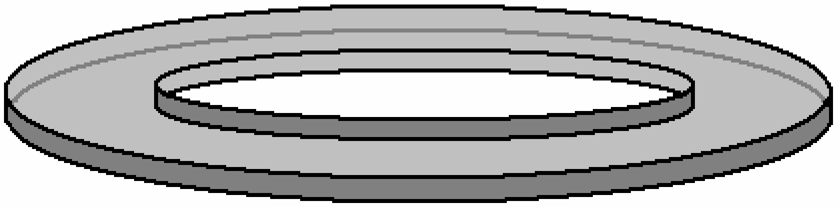
The power control circuit incorporates a solid state switch in the form of a power transistor or a MOSFET. It responds to the control signal **58** by turning the solid state switch ON and OFF to initiate and terminate coil excitation. Instantaneous voltage amplitude supplied to the coils during excitation is controlled by means of potentiometer **P**. Motor speed and torque are thus responsive to potentiometer adjustments.

The device is also adaptable for operation as a motor using a commutator and brushes for control of coil excitation. In this case, the commutator and brushes replace the programmable logic controller and the power control circuit as the means for providing pulsed DC excitation. This approach is less flexible but perhaps more efficient than the programmable control system described earlier.

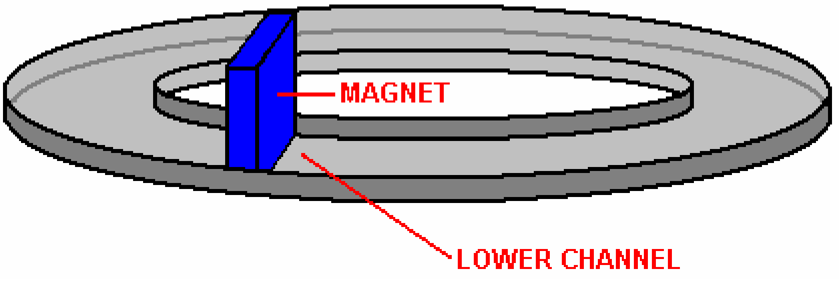
It will now be recognised that a novel and useful generator has been provided in accordance with the stated objects of the invention, and while but a few embodiments of the invention have been illustrated and described it will be apparent to those skilled in the art that various changes and modifications may be made without departing from the spirit of the invention or from the scope of the appended claims.

Notes:

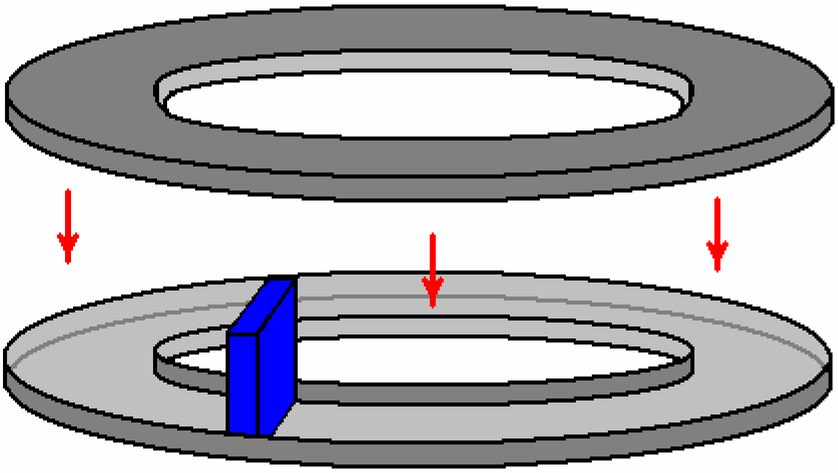
I found it a little difficult to visualise the carousel part, so the following may be helpful for some people. The "carousel" is formed from two circular plastic channels like this:



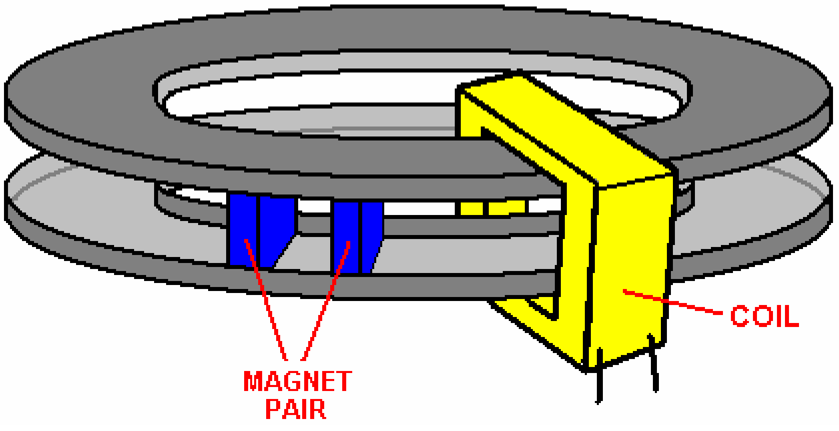
These channels are placed, one below and one above, nine pairs of carousel magnets (coloured blue in some of the patent diagrams shown above. Each carousel magnet sits in the lower channel:



And these magnets are secured as a unit by an identical plastic channel inverted and placed on top of the magnet set:



And this ring assembly of magnets spins inside the wire coils used to generate the electrical output. The ring spins inside the coils because the nine pairs of magnets in the ring, lock in place opposite the matching nine pairs of magnets in the rotor and the magnetic force and rotor rotation causes the ring to spin inside the coils.



PAVEL IMRIS: OPTICAL GENERATOR

US Patent 3,781,601 25th December 1973 Inventor: Pavel Imris

OPTICAL GENERATOR OF AN ELECTROSTATIC FIELD HAVING LONGITUDINAL OSCILLATION AT LIGHT FREQUENCIES FOR USE IN AN ELECTRICAL CIRCUIT

Please note that this is a re-worded excerpt from this patent. It describes a gas-filled tube which allows many standard 40-watt fluorescent tubes to be powered using less than 1-watt of power each.

ABSTRACT

An Optical generator of an electrostatic field at light frequencies for use in an electrical circuit, the generator having a pair of spaced-apart electrodes in a gas-filled tube of quartz glass or similar material with at least one capacitor cap or plate adjacent to one electrode and a dielectric filled container enclosing the tube, the generator substantially increasing the electrical efficiency of the electrical circuit.

BACKGROUND OF THE INVENTION

This invention relates to improved electrical circuits, and more particularly to circuits utilising an optical generator of an electrostatic field at light frequencies.

The measure of the efficiency of an electrical circuit may broadly be defined as the ratio of the output energy in the desired form (such as light in a lighting circuit) to the input electrical energy. Up to now, the efficiency of many circuits has not been very high. For example, in a lighting circuit using 40 watt fluorescent lamps, only about 8.8 watts of the input energy per lamp is actually converted to visible light, thus representing an efficiency of only about 22%. The remaining 31.2 watts is dissipated primarily in the form of heat.

It has been suggested that with lighting circuits having fluorescent lamps, increasing the frequency of the applied current will raise the overall circuit efficiency. While at an operating frequency of 60 Hz, the efficiency is 22%, if the frequency is raised to 1 Mhz, the circuit efficiency would only rise to some 25.5%. Also, if the input frequency were raised to 10 Ghz, the overall circuit efficiency would only be 35%.

SUMMARY OF THE PRESENT INVENTION

The present invention utilises an optical electrostatic generator which is effective for producing high frequencies in the visible light range of about 10^{14} to 10^{23} Hz. The operation and theory of the optical electrostatic generator has been described and discussed in my co-pending application serial No. 5,248, filed on 23rd January 1970. As stated in my co-pending application, the present optical electrostatic generator does not perform in accordance with the accepted norms and standards of ordinary electromagnetic frequencies.

The optical electrostatic generator as utilised in the present invention can generate a wide range of frequencies between several Hertz and those in the light frequency. Accordingly, it is an object of the present invention to provide improved electrical energy circuits utilising my optical electrostatic generator, whereby the output energy in the desired form will be substantially more efficient than possible to date, using standard circuit techniques and equipment. It is a further object of the present invention to provide such a circuit for use in fluorescent lighting or other lighting circuits. It is also an object of the present invention to provide a circuit with may be used in conjunction with electrostatic precipitators for dust and particle collection and removal, as well as many other purposes.

F/G. 3

DESCRIPTION OF THE ILLUSTRATED EMBODIMENTS

Referring to the drawings and to **Fig.1** in particular, a low voltage circuit utilising an optical electrostatic generator is shown. As shown in **Fig.1**, a source of alternating current electrical energy **10**, is connected to a lighting circuit. Connected to one tap of the power source **10** is a rectifier **12** for utilisation when direct current is required. The illustrated circuit is provided with a switch **14** which may be opened or closed depending on whether AC or DC power is used. Switch **14** is opened and a switch **16** is closed when AC is used. With switch **14** closed and switch **16** open, the circuit operates as a DC circuit.

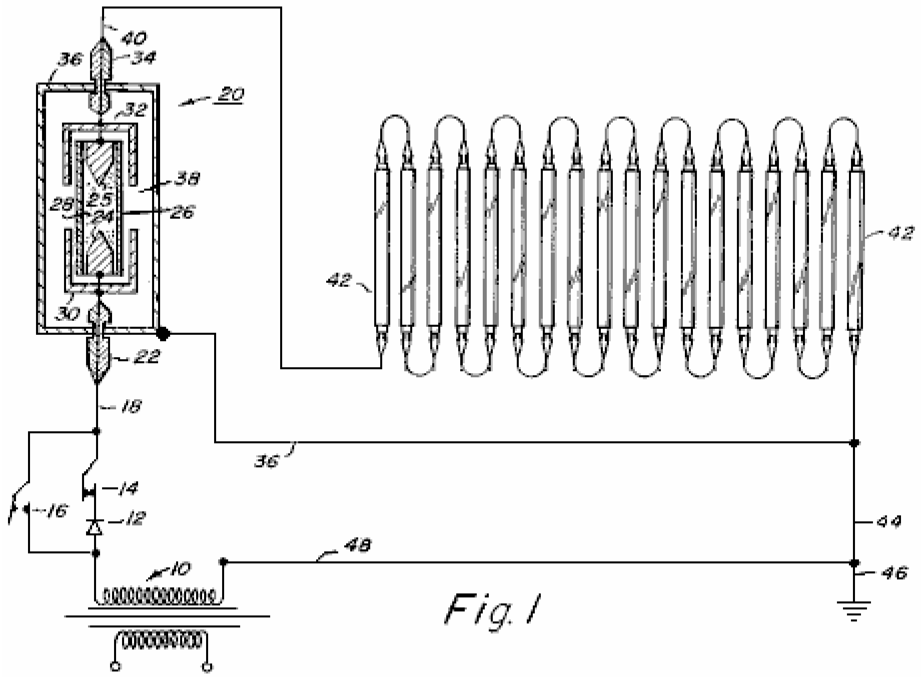

Fig. 1

Extending from switches **14** and **16** is conductor **18** which is connected to an optical electrostatic generator **20**. Conductor **18** is passed through an insulator **22** and connected to an electrode **24**. Spaced from electrode **24** is a second electrode **25**. Enclosing electrodes **24** and **25**, which preferably are made of tungsten or similar material, is a quartz glass tube **26** which is filled with an ionisable gas **28** such as xenon or any other suitable ionisable gas such as argon, krypton, neon, nitrogen or hydrogen, as well as the vapour of metals such as mercury or sodium.

Surrounding each end of tube **26** and adjacent to electrodes **24** and **25**, are capacitor plates **30** and **32** in the form of caps. A conductor is connected to electrode **25** and passed through a second insulator **34**. Surrounding the tube, electrodes and capacitor caps is a metal envelope in the form of a thin sheet of copper or other metal such as aluminium. Envelope **36** is spaced from the conductors leading into and out of the generator by means of insulators **22** and **34**. Envelope **36** is filled with a dielectric material such as transformer oil, highly purified distilled water, nitro-benzene or any other suitable liquid dielectric. In addition, the dielectric may be a solid such as ceramic material with relatively small molecules.

A conductor **40** is connected to electrode **25**, passed through insulator **24** and then connected to a series of fluorescent lamps **42** which are connected in series. It is the lamps **42** which will be the measure of the efficiency of the circuit containing the optical electrostatic generator **20**. A conductor **44** completes the circuit from the fluorescent lamps to the tap of the source of electrical energy **10**. In addition, the circuit is connected to a ground **46** by another conductor **48**. Envelope **36** is also grounded by lead **50** and in the illustrated diagram, lead **50** is connected to the conductor **44**.

The capacitor caps or plates **30** and **32**, form a relative capacitor with the discharge tube. When a high voltage is applied to the electrode of the discharge tube, the ions of gas are excited and brought to a higher potential than their environment, i.e. the envelope and the dielectric surrounding it. At this point, the ionised gas in effect becomes one plate of a relative capacitor in co-operation with the capacitor caps or plates **30** and **32**.

When this relative capacitor is discharged, the electric current does not decrease as would normally be expected. Instead, it remains substantially constant due to the relationship between the relative capacitor and an absolute capacitor which is formed between the ionised gas and the spaced metal envelope **36**. An oscillation effect occurs in the relative capacitor, but the electrical condition in the absolute capacitor remains substantially constant.

As also described in the co-pending application serial No. 5,248, there is an oscillation effect between the ionised gas in the discharge lamp and the metallic envelope **36** will be present if the capacitor caps are eliminated, but the efficiency of the electrostatic generator will be substantially decreased.

The face of the electrode can be any desired shape. However, a conical point of 60^0 has been found to be satisfactory and it is believed to have an influence on the efficiency of the generator.

In addition, the type of gas selected for use in tube **26**, as well as the pressure of the gas in the tube, also affect the efficiency of the generator, and in turn, the efficiency of the electrical circuit.

To demonstrate the increased efficiency of an electrical circuit utilising the optical electrostatic generator of the present invention as well as the relationship between gas pressure and electrical efficiency, a circuit similar to that shown in **Fig.1** may be used with 100 standard 40 watt, cool-white fluorescent lamps connected in series. The optical electrostatic generator includes a quartz glass tube filled with xenon, with a series of different tubes being used because of the different gas pressures being tested.

Table 1 shows the data to be obtained relating to the optical electrostatic generator. **Table 2** shows the lamp performance and efficiency for each of the tests shown in **Table 1**. The following is a description of the data in each of the columns of **Tables 1 and 2**.

Column	Description
B	**Gas used in discharge tube**
C	**Gas pressure in tube** (in torrs)
D	**Field strength across the tube** (measured in volts per cm. of length between the electrodes)
E	**Current density** (measured in microamps per sq. mm. of tube cross-sectional area)
F	**Current** (measured in amps)
G	**Power across the tube** (calculated in watts per cm. of length between the electrodes)
H	**Voltage per lamp** (measured in volts)
K	**Current** (measured in amps)
L	**Resistance** (calculated in ohms)
M	**Input power per lamp** (calculated in watts)
N	**Light output** (measured in lumens)

The design of a tube construction for use in the optical electrostatic generator of the type used in **Fig.1**, may be accomplished by considering the radius of the tube, the length between the electrodes in the tube and the power across the tube.

If **R** is the minimum inside radius of the tube in centimetres, **L** the minimum length in centimetres between the electrodes, and **W** the power in watts across the lamp, the following formula can be obtained from **Table 1:**

R = (Current [A] / Current Density [A/sq.mm]) / pi

L = 8R

W = L[V/cm] x A

For example, for Test No. 18 in Table 1:
The current is 0.1818 A,
The current density 0.000353 A/sq.mm and
The Voltage Distribution is 122.8 V/cm; therefore

R = $(0.1818 / 0.000353)^2$ /3.14 = 12.80 mm.

L = 8 x R = 8 * 12.8 = 102.4 mm (10.2 cm.)

W = 10.2 x 122.8 x 0.1818 = 227.7 VA or 227.7 watts

The percent efficiency of operation of the fluorescent lamps in Test No. 18 can be calculated from the following equation:

% Efficiency = (Output Energy/Input energy) x 100

Across a single fluorescent lamp, the voltage is 60 volts and the current is 0.1818 amps therefore the input energy to the lamp **42** is 10.90 Watts. The output of the fluorescent lamp is 3,200 lumens which represents 8.8 Watts power of light energy. Thus, the one fluorescent lamp is operating at 80.7% efficiency under these conditions.

However, when the optical generator is the same as described for Test No. 18 and there are 100 fluorescent lamps in series in the circuit, the total power input is 227.7 watts for the optical generator and 1,090 watts for 100 fluorescent lamps, or a total of 1,318 watts. The total power input normally required to operate the 100 fluorescent lamps in a normal circuit would be 100 x 40 = 4,000 watts. So by using the optical generator in the circuit, about 2,680 watts of energy is saved.

Table 1 is an example of the functioning of this invention for a particular fluorescent lamp (40 watt cool white). However, similar data can be obtained for other lighting applications, by those skilled in the art.

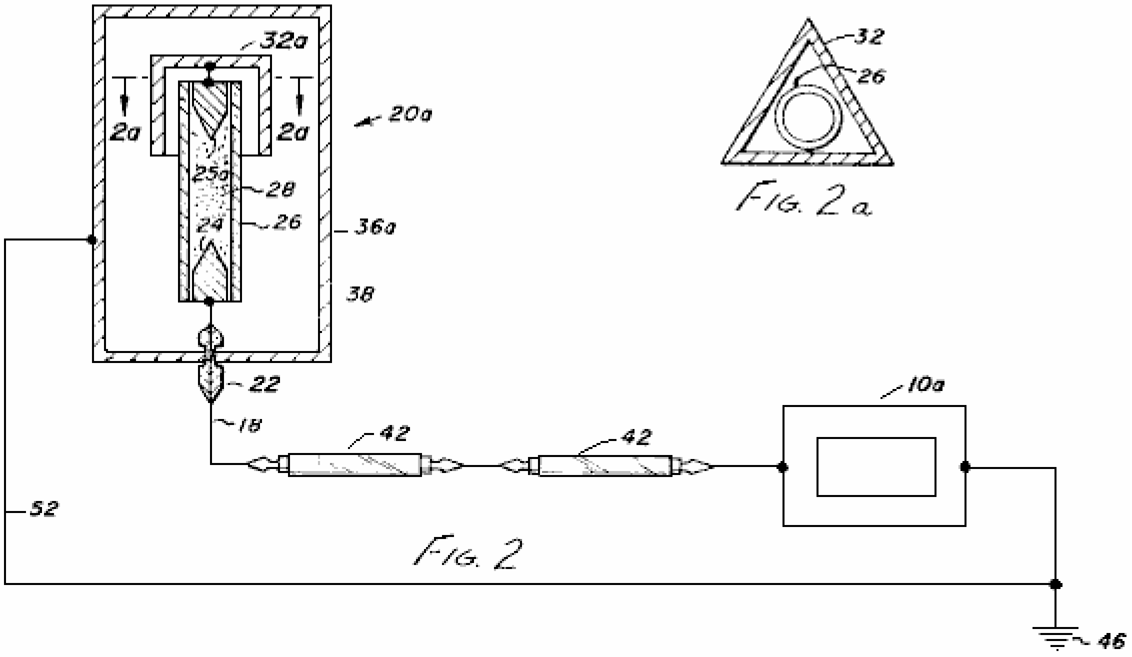

FIG. 2a.

FIG. 2

In **Fig.2**, a circuit is shown which uses an optical electrostatic generator **20a**, similar to generator **20** of **Fig.1**. In generator **20**, only one capacitor cap **32a** is used and it is preferably of triangular cross-sectional design. In addition, the second electrode **25a** is connected directly back into the return conductor **52**, similar to the arrangement shown in my co-pending application serial No. 5,248, filed 23rd January 1970.

This arrangement is preferably for very high voltage circuits and the generator is particularly suited for DC usage.

In **Fig.2**, common elements have received the same numbers which were used in **Fig.1**.

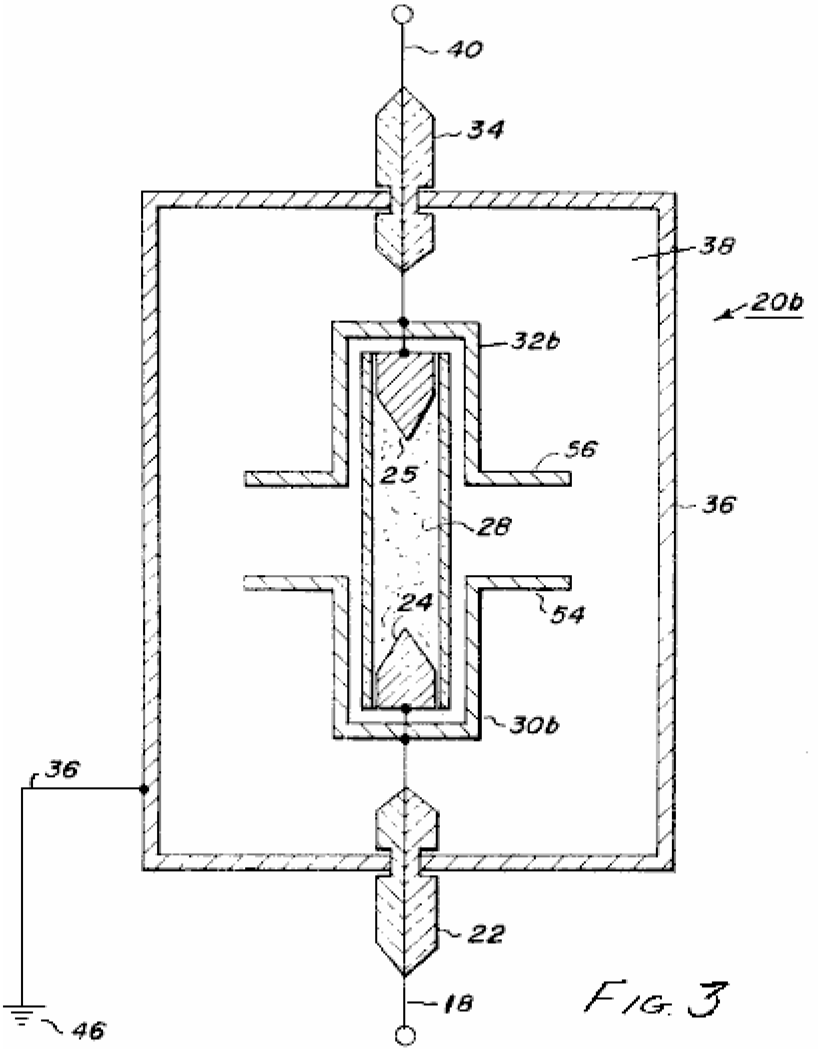

FIG. 3

In **Fig.3**, still another embodiment of an optical electrostatic generator **20b** is shown. This generator is particularly suited for use with AC circuits. In this embodiment, the capacitor plates **30b** and **32b** have flanges **54** and **56** which extend outwards towards the envelope **36**. While the utilisation of the optical electrostatic generator has been described in use in a fluorescent lighting circuit, it is to be understood that many other types of circuits may be used. For example, the high-voltage embodiment may be used in a variety of circuits such as flash lamps, high-speed controls, laser beams and high-energy pulses. The generator is also particularly usable in a circuit including electrostatic particle precipitation in air pollution control devices, chemical synthesis in electrical discharge systems such as ozone generators and charging means for high-voltage generators of the Van de Graff type, as well as particle accelerators. To those skilled in the art, many other uses and circuits will be apparent.

HAROLD COLMAN & RONALD SEDDON-GILLESPIE: 70-YEAR BATTERY

Patent GB 763,062 5th December 1956 Inventors: Harold Colman and Ronald Seddon-Gillespie

APPARATUS FOR PRODUCING AN ELECTRIC CURRENT

This patent shows the details of a lightweight device which can produce electricity using a self-powered electromagnet and chemical salts. The working life of the device before needing a recharge is estimated at some seventy years. The operation is controlled by a transmitter which bombards the chemical sample with 300 MHz radio waves. This produces radioactive emissions from the chemical mixture for a period of one hour maximum, so the transmitter needs to be run for fifteen to thirty seconds once every hour. The chemical mixture is shielded by a lead screen to prevent harmful radiation reaching the user. The output from the tiny device described is estimated to be some 10 amps at 100 to 110 volts DC.

DESCRIPTION

This invention relates to a new apparatus for producing electric current the apparatus being in the form of a completely novel secondary battery. The object of this invention is to provide apparatus of the above kind which is considerably lighter in weight than, and has an infinitely greater life than a known battery or similar characteristics and which can be re-activated as and when required in a minimum of time.

According to the present invention we provide apparatus comprising a generator unit which includes a magnet, a means for suspending a chemical mixture in the magnetic field, the mixture being composed of elements whose nuclei becomes unstable as a result of bombardment by short waves so that the elements become radio-active and release electrical energy, the mixture being mounted between, and in contact with, a pair of different metals such as copper and zinc, a capacitor mounted between those metals, a terminal electrically connected to each of the metals, means for conveying the waves to the mixture and a lead shield surrounding the mixture to prevent harmful radiation from the mixture.

The mixture is preferably composed of the elements Cadmium, Phosphorus and Cobalt having Atomic Weights of 112, 31 and 59 respectively. The mixture, which may be of powdered form, is mounted in a tube of non-conducting, high heat resistivity material and is compressed between granulated zinc at one end of the tube and granulated copper at the other end, the ends of the tube being closed by brass caps and the tube being carried in a suitable cradle so that it is located between the poles of the magnet. The magnet is preferably an electro-magnet and is energised by the current produced by the unit.

The means for conveying the waves to the mixture may be a pair of antennae which are exactly similar to the antennae of the transmitter unit for producing the waves, each antenna projecting from and being secured to the brass cap at each end of the tube.

The transmitter unit which is used for activating the generator unit may be of any conventional type operating on ultra-shortwave and is preferably crystal controlled at the desired frequency.

Fig.3 is a schematic circuit diagram.

In the form of our invention illustrated, the generator unit comprises a base **10** upon which the various components are mounted. This base **10**, having projecting upwards from it a pair of arms **11**, which form a cradle housing **12** for a quartz tube **13**, the cradle **12** preferably being made of spring material so that the tube **13** is firmly, yet removably held in position. The arms **11** are positioned relative to the poles **14** of an electromagnet **15** so that the tube **13** is located immediately between the poles of the magnet so as to be in the strongest magnetic field created by the electromagnet. The magnet serves to control the alpha and beta rays emitted by the cartridge when it is in operation.

The ends of the quartz tube **13** are each provided with a brass cap **16**, and these caps **16** are adapted to engage within the spring cradles **12** and the coils **17** associated with the magnet being so arranged that if the base **10** of the unit is in a horizontal plane, the poles **14** of the magnet are in a substantially vertical plane.

Also connected across the cradles is a lead capacitor **18** which may conveniently be housed in the base **10** of the unit and connected in parallel with this capacitor **18** is a suitable high frequency inductance coil **19**. The unit is provided with a lead shield **20** so as to prevent harmful radiation from the quartz tube as will be described later.

The quartz tube **13** has mounted in it, at one end, a quantity of granulated copper which is in electrical contact with the brass cap **16** at that end of the tube. Also mounted within the tube and in contact with the granulated copper is a chemical mixture which is in powdered form and which is capable of releasing electrical energy and which becomes radioactive when subjected to bombardment by ultra-short radio waves.

Mounted in the other end of the tube, and in contact with the other end of the powdered chemical mixture is a quantity of granulated zinc which is itself in contact with the brass cap on this end of the tube, the arrangement being that the chemical mixture is compressed between the granulated copper and the granulated zinc.

Projecting outwards from each brass cap **16**, and electrically connected to them, is an antenna **21**. Each antenna **21** corresponding exactly in dimension, shape and electrical characteristics to the antenna associated with a transmitter unit which is to produce the ultra shortwaves mentioned earlier.

The electromagnet **15** is conveniently carried by a centrally positioned pillar **22** which is secured to the base **10**. At the upper end of pillar **22** there is a cross-bar **23**, which has the high frequency coil **19** attached to one end of it. The other end of the cross-bar **23** is bent around into the curved shape as shown at **24** and is adapted to bear against a curved portion **25** of the base **26** of the electromagnet **15**. A suitable locking device is provided for holding the curved portions **24** and **25** in the desired angular position, so that the position of the poles **14** of the electromagnet can be adjusted about the axis of the quartz tube **13**.

The transmitter unit is of any suitable conventional type for producing ultra shortwaves and may be crystal controlled to ensure that it operates at the desired frequency with the necessity of tuning. If the transmitter is only required to operate over a short range, it may conveniently be battery powered but if it is to operate over a greater range, then it may be operated from a suitable electrical supply such as the mains. If the transmitter is to be tuned, then the tuning may be operated by a dial provided with a micrometer vernier scale so that the necessary tuning accuracy may be achieved.

The mixture which is contained within the quartz tube is composed of the elements Cadmium, Phosphorus and Cobalt, having atomic weights 112, 31 and 59 respectively. Conveniently, these elements may be present in the following compounds, and where the tube is to contain thirty milligrams of the mixture, the compounds and their proportions by weight are:

1 Part of $Co\ (No_3)\ 2\ 6H_2O$
2 Parts of $CdCl_2$
3 Parts of $3Ca\ (Po_3)\ 2 + 10C$.

The cartridge which consists of the tube **13** with the chemical mixture in it is preferably composed of a number of small cells built up in series. In other words, considering the cartridge from one end to the other, at one end and in contact with the brass cap, there would be a layer of powdered copper, then a layer of the chemical mixture, then a layer of powdered zinc, a layer of powdered copper, etc. with a layer of powdered zinc in contact with the brass cap at the other end of the cartridge. With a cartridge some forty five millimetres long and five millimetres diameter, some fourteen cells may be included.

The cradles **12** in which the brass caps **16** engage, may themselves form terminals from which the output of the unit may be taken. Alternatively, a pair of terminals **27** may be connected across the cradles **12**, these terminals **27** being themselves provided with suitable antennae **28**, which correspond exactly in dimensions, shape and electrical characteristics to the antennae associated with the transmitter, these antennae **28**, replacing the antennae **21**.

In operation with the quartz tube containing the above mixture located between the granulated copper and the granulated zinc and with the tube itself in position between the poles of the magnet, the transmitter is switched on and the ultra shortwaves coming from it are received by the antennae mounted at each end of the tube and in contact with the copper and zinc respectively, the waves being thus passed through the copper and zinc and through the mixture so that the mixture is bombarded by the short waves and the Cadmium, Phosphorus and Cobalt associated with the mixture become radioactive and release electrical energy which is transmitted to the granulated copper and granulated zinc, causing a current to flow between them in a similar manner to the current flow produced by a thermo couple. It has been established that with a mixture having the above composition, the optimum release of energy is obtained when the transmitter is operating at a frequency of 300 MHz.

The provision of a quartz tube is necessary for the mixture evolves a considerable amount of heat while it is reacting to the bombardment of the short waves. It is found that the tube will only last for one hour and that the tube will become discharged after an hours operation, that is to say, the radioactiveness of the tube will only last for one hour and it is therefore necessary, if the unit is to be run continuously, for the transmitter to be operated for a period of some fifteen to thirty seconds duration once every hour.

With a quartz tube having an overall length of some forty five millimetres and an inside diameter of five millimetres and containing thirty milligrams of the chemical mixture, the estimated energy which will be given off from the tube for a discharge of one hour, is 10 amps at between 100 and 110 volts. To enable the tube to give off this discharge, it is only necessary to operate the transmitter at the desired frequency for a period of some fifteen to thirty seconds duration.

The current which is given off by the tube during its discharge is in the form of direct current. During the discharge from the tube, harmful radiations are emitted in the form of gamma rays, alpha rays and beta rays and it is therefore necessary to mount the unit within a lead shield to prevent the harmful radiations from affecting personnel and objects in the vicinity of the unit. The alpha and beta rays which are emitted from the cartridge when it is in operation are controlled by the magnet.

When the unit is connected up to some apparatus which is to be powered by it, it is necessary to provide suitable fuses to guard against the cartridge being short-circuited which could cause the cartridge to explode.

The estimated weight of such a unit including the necessary shielding, per kilowatt hour output, is approximately 25% of any known standard type of accumulator which is in use today and it is estimated that the life of the chemical mixture is probably in the region of seventy to eighty years when under constant use.

It will thus be seen that we have provided a novel form of apparatus for producing an electric current, which is considerably lighter than the standard type of accumulator at present known, and which has an infinitely greater life than the standard type of accumulator, and which can be recharged or reactivated as and when desired and from a remote position depending on the power output of the transmitter. Such form of battery has many applications.

Patent US 6,208,061 27th March 2001 Inventor: Jong-Sok An

NO-LOAD GENERATOR

Electrical power is frequently generated by spinning the shaft of a generator which has some arrangement of coils and magnets contained within it. The problem is that when current is drawn from the take-off coils of a typical generator, it becomes much more difficult to spin the generator shaft. The cunning design shown in this patent overcomes this problem with a simple design in which the effort required to turn the shaft is not altered by the current drawn from the generator.

ABSTRACT

A generator of the present invention is formed of ring permanent magnet trains 2 and 2' attached and fixed on to two orbits 1 and 1' about a rotational axis 3, magnetic induction primary cores 4 and 4' attached and fixed above outer peripheral surfaces of the ring permanent magnet trains 2 and 2' at a predetermined distance from the outer peripheral surfaces, magnetic induction secondary cores 5 and 5' attached and fixed on to the magnetic induction primary cores 4 and 4' and each having two coupling, holes 6 and 6' formed therein, tertiary cores 8 and 8' inserted for coupling respectively into two coupling holes 6 and 6' of each of the associated magnetic induction secondary cores 5 and 5' opposite to each other, and responsive coils 7 and 7'. The ring permanent magnetic trains 2 and 2' are formed of 8 sets of magnets with alternating N and S poles, and magnets associated with each other in the axial direction have opposite polarities respectively and form a pair.

DESCRIPTION

TECHNICAL FIELD

The present invention relates to generators, and particularly to a load-free generator which can maximise the generator efficiency by erasing or eliminating the secondary repulsive load exerted on the rotor during electric power generation.

BACKGROUND ART

The generator is a machine which converts mechanical energy obtained from sources of various types of energy such as physical, chemical or nuclear power energy, for example, into electric energy. Generators based on linear motion have recently been developed while most generators are structured as rotational type generators. Generation of electromotive force by electromagnetic induction is a common principle to generators regardless of their size or whether the generator is AC or DC generator.

The generator requires a strong magnet such as permanent magnet and electromagnet for generating magnetic field as well as a conductor for generating the electromotive force, and the generator is structured to enable one of them to rotate relative to the other. Depending on which of the magnet and the conductor rotates, generators can be classified into rotating-field type generators in which the magnetic field rotates and rotating-armature type generators in which the conductor rotates.

Although the permanent magnet can be used for generating the magnetic field, the electromagnet is generally employed which is formed of a magnetic field coil wound around a core to allow direct current to flow through them. Even if a strong magnet is used to enhance the rotational speed, usually the electromotive force produced from one conductor is not so great. Thus, in a generally employed system, a large number of conductors are provided in the generator and the electromotive forces generated from respective conductare serially added up so as to achieve a high electric power.

As discussed above, a usual generator produces electricity by mechanically rotating a magnet (or permanent magnet) or a conductor (electromagnet, electrically responsive coil and the like) while reverse current generated at this time by magnetic induction (electromagnetic induction) and flowing through the coil causes magnetic force which pulls the rotor so that the rotor itself is subjected to unnecessary load which reaches at least twice the electric power production.

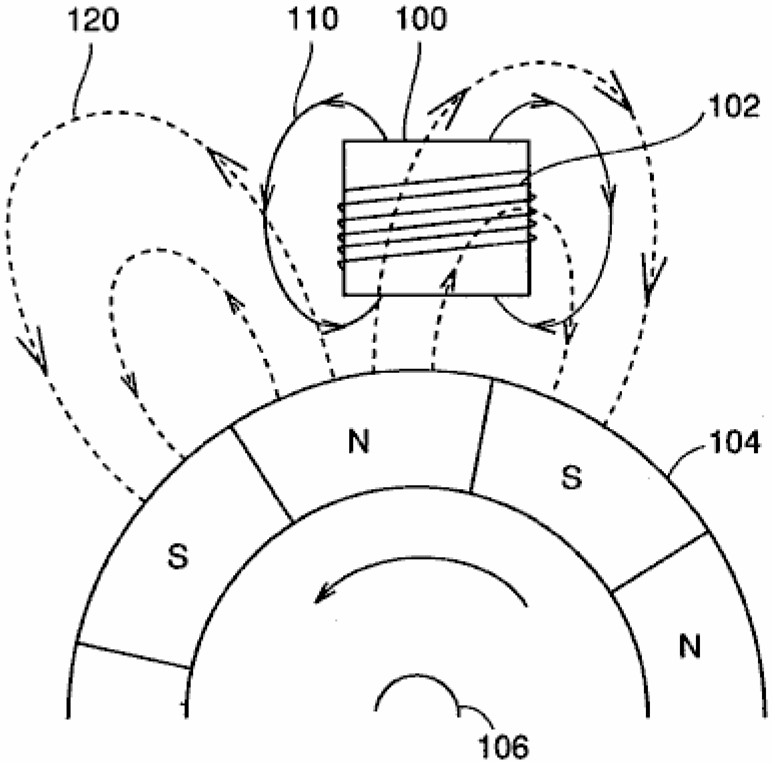

Fig.6 illustrates that the load as discussed above is exerted on a rotor in a rotating-field type generator mentioned above.

Referring to **Fig.6**, a permanent magnet train **104** is arranged about an axis of rotation **106** such that N poles and S poles are alternately located on the outer peripheral surface of the train. At a certain distance outward from the outer periphery of permanent magnet train **104**, a magnetic induction core **100** is arranged and a coil **102** is wound around magnetic induction core **100**.

As permanent magnet train **104** rotates, the magnetic field produced in the coil by permanent magnet train **104** changes to cause induced current to flow through coil **102**. This induced current allows coil **102** to generate a magnetic field **110** which causes a repulsive force exerted on permanent magnet train **104** in the direction which interferes the rotation of the magnet train.

For example, in the example shown in **Fig.6**, the S pole of magnetic field **110** faces permanent magnet train **104**. The S pole of permanent magnet train **104** approaches coil **102** because of rotation of permanent magnet train **104**, resulting in the repulsive force as described above.

If reverse current flows in a responsive coil of an armature wound around a magnetic induction core of a generator so that the resulting load hinders the rotor from rotating, reverse magnetic field of the armature responsive coil becomes stronger in proportion to the electricity output and accordingly a load corresponding to at least twice the instantaneous consumption could occur.

If electric power of 100W is used, for example, reverse magnetic field of at least 200W is generated so that an enormous amount of load affects the rotor to interfere the rotation of the rotor.

All of the conventional generators are subjected to not only a mechanical primary load, i.e. the load when the electric power is not consumed but a secondary load due to reverse current which is proportional to electric power consumption and consequently subjected to a load of at least twice the instantaneous consumption.

Such an amount of the load is a main factor of reduction of the electric power production efficiency, and solution of the problem above has been needed.

DISCLOSURE OF THE INVENTION

One object of the present invention is to provide a generator capable of generating electric power with high efficiency by cancelling out the secondary load except the mechanical load of the generator, i.e. cancelling out the load which is generated due to reverse current of a responsive coil of an armature wound around a magnetic induction core, so as to entirely prevent the secondary load from being exerted.

In short, the present invention is applied to a load-free generator including a rotational axis, a first ring magnet train, a second ring magnet train, a first plurality of first magnetic induction primary cores, a first plurality of second magnetic induction primary cores, a first responsive coil, and a second responsive coil.

The first ring magnet train has N poles and S poles successively arranged on an outer periphery of a first rotational orbit about the rotational axis. The second ring magnet train has magnets successively arranged on an outer periphery of a second rotational orbit about the rotational axis at a predetermined distance from the first rotational orbit such that the polarities of the magnets on the second rotational orbit are opposite to the polarities at opposite locations on the first rotational orbit respectively. The first plurality of first magnetic induction primary cores are fixed along a first peripheral surface of the first ring magnet train at a predetermined distance from the first peripheral surface. The first plurality of second magnetic induction primary cores are fixed along a second peripheral surface of the second ring magnet train at a predetermined distance from the second peripheral surface. A first plurality of first coupling magnetic induction cores and a first plurality of second coupling magnetic induction cores are provided in pairs to form a closed magnetic circuit between the first and second magnetic induction primary cores opposite to each other in the direction of the rotational axis. The first responsive coil is wound around the first coupling magnetic induction core. The second responsive coil is wound around the second coupling magnetic induction core, the direction of winding of the second responsive coil being reversed relative to the first responsive coil.

Preferably, in the load-free generator of the invention, the first ring magnet train includes a permanent magnet train arranged along the outer periphery of the first rotational orbit, and the second ring magnet train includes a permanent magnet train arranged along the outer periphery of the second rotational orbit.

Still preferably, the load-free generator of the present invention further includes a first plurality of first magnetic induction secondary cores provided on respective outer peripheries of the first magnetic induction primary cores and each having first and second coupling holes, and a first plurality of second magnetic induction secondary cores provided on respective outer peripheries of the second magnetic induction primary cores and each having third and fourth coupling holes. The first coupling magnetic induction cores are inserted into the first and third coupling holes to couple the first and second magnetic induction secondary cores, and the second coupling magnetic induction cores are inserted into the second and fourth coupling holes to couple the first and second magnetic induction secondary cores.

Alternatively, the load-free generator of the present invention preferably has a first plurality of first responsive coils arranged in the rotational direction about the rotational aids that are connected zigzag to each other and a first plurality of second responsive coils arranged in the rotational direction about the rotational axis that are connected zigzag to each other.

Alternatively, in the load-free generator of the present invention, preferably the first plurality is equal to 8, and the 8 first responsive coils arranged in the rotational direction about the rotational axis are connected zigzag to each other, and the 8 second responsive coils arranged in the rotational direction about the rotational axis are connected zigzag to each other.

Accordingly, a main advantage of the present invention is that two responsive coils wound respectively in opposite directions around a paired iron cores are connected to cancel reverse magnetic forces generated by reverse currents (induced currents) flowing through the two responsive coils, so that the secondary load which interferes the rotation of the rotor is totally prevented and thus a load-free generator can be provided which is subjected to just a load which is equal to or less than mechanical load when electric power production is not done, i.e. the rotational load even when the generator is operated to the maximum.

Another advantage of the present invention is that the reverse magnetic force, as found in the conventional generators, due to reverse current occurring when the rotor rotates is not generated, and accordingly load of energy except the primary gravity of the rotor and dynamic energy of the rotor is eliminated to increase the amount of electricity output relative to the conventional electric power generation system and thus enhance the electric power production and economic efficiency.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig.1 is a cross sectional view of a rotating-field type generator according to an embodiment of the present invention illustrating an arrangement a permanent magnet, magnetic induction cores and coils.

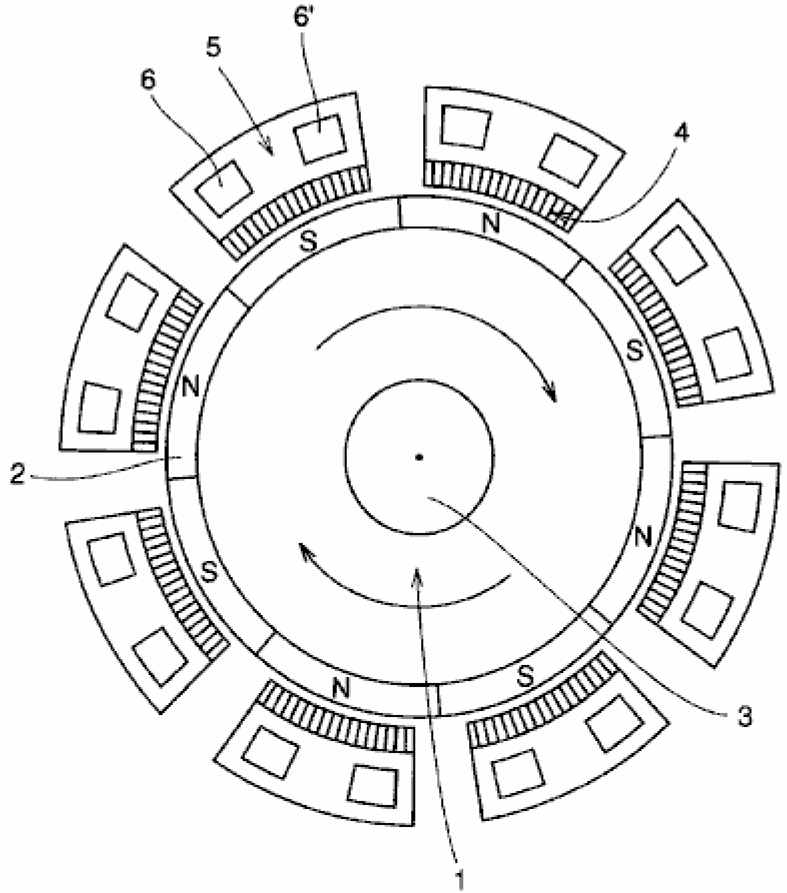

FIG. 1

Fig.2 is a partial schematic view illustrating a magnetic array of the permanent magnet rotor and an arrangement of one of magnetically responsive coils placed around that rotor in an embodiment of the present invention.

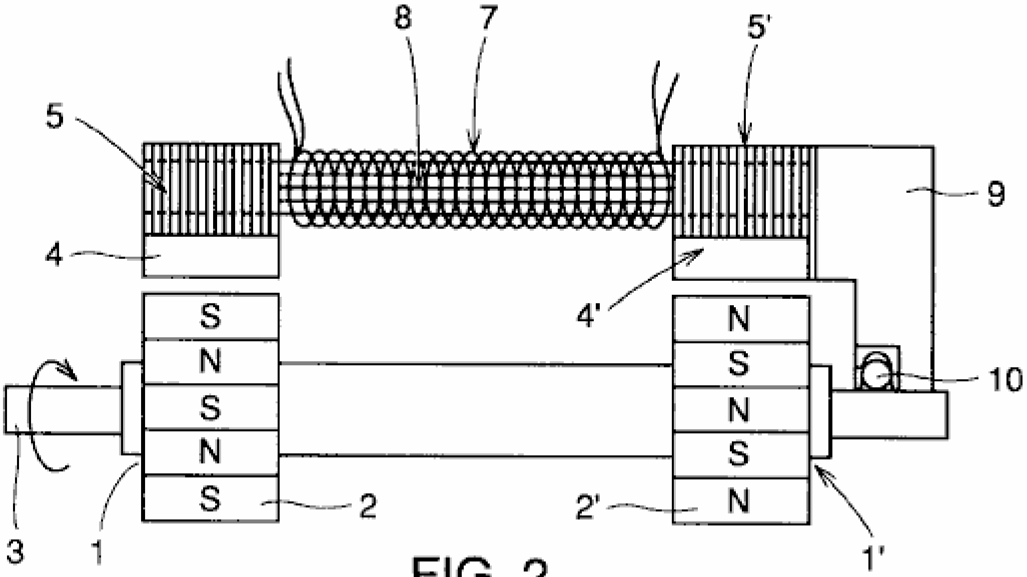

FIG. 2

Fig.3 illustrates a structure of the magnetically responsive coils and cores in the embodiment of the present invention.

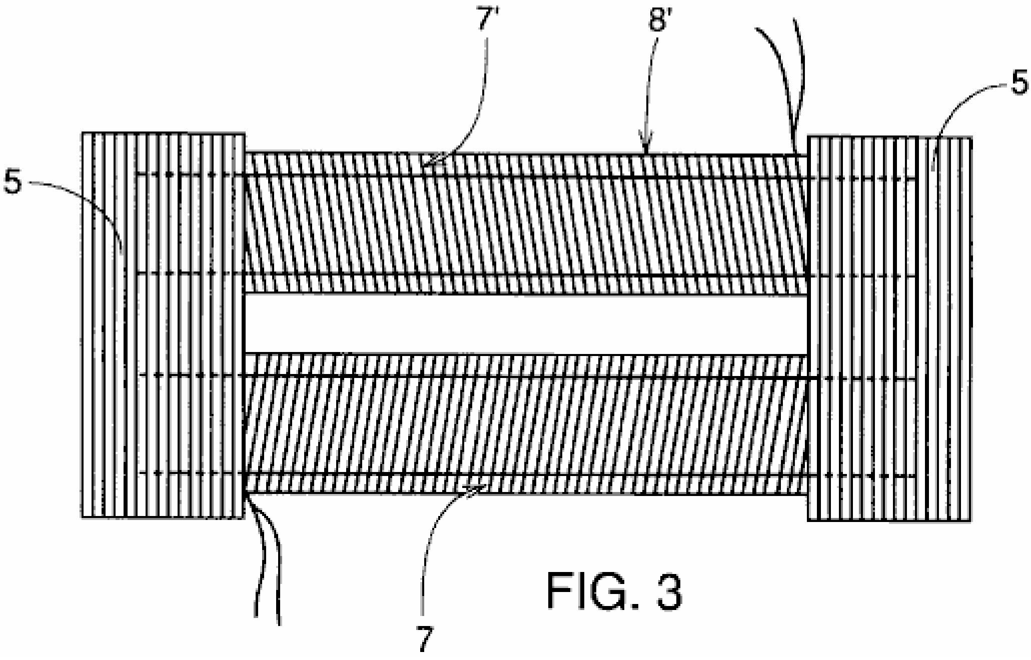

FIG. 3

Fig.4 is an enlarged plan view of magnetically sensitive cores and coil portions of the load-free generator of the present invention illustrating magnetic flow therethrough.

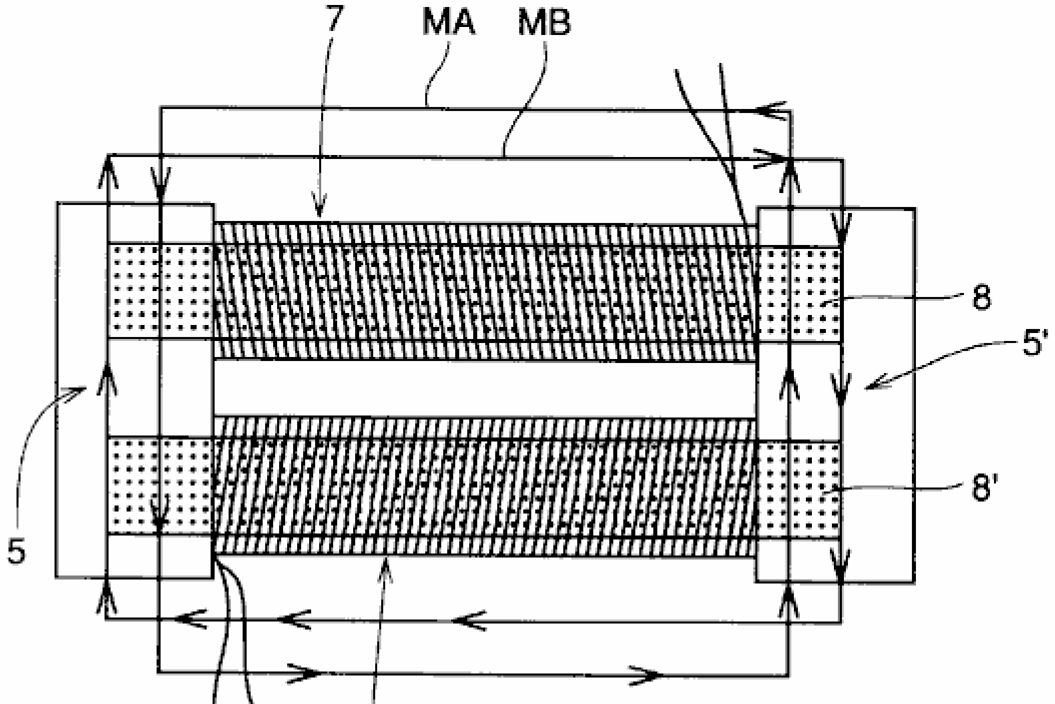

FIG. 4

Fig.5 is an exploded view about a central axis showing the interconnection of magnetic field coils which are respectively wound around tertiary cores surrounding the permanent magnet rotor in FIG. 1 according to the present invention.

BEST MODES FOR CARRYING OUT THE INVENTION

The structure and operation of a load-free generator according to the present invention are now described in conjunction with the drawings.

Fig.1 illustrates a cross sectional structure of the load-free generator of the invention perpendicular to a rotational axis **3**.

Fig.2 partially illustrates a cross sectional structure of the load-free generator of the invention in parallel to rotational axis **3**. Specifically, in **Fig.2**, only one of eight sets of magnetic induction primary cores **4** and **4'** arranged around rotational axis **3** as described below is representatively shown.

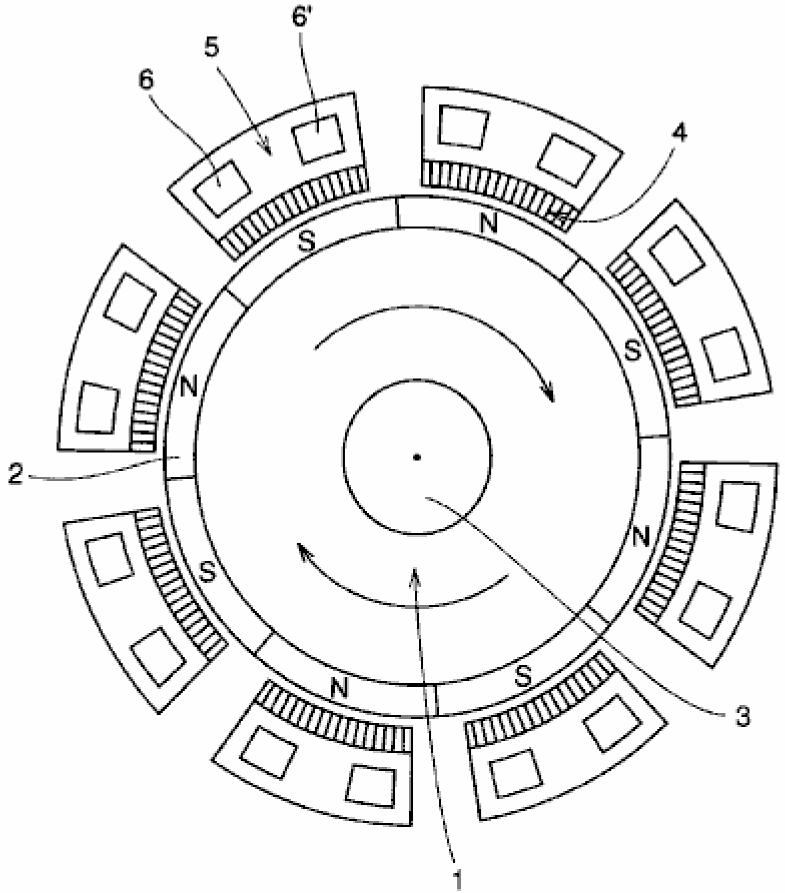

FIG. 1

Referring to **Fig.1** and **Fig.2**, the structure of the load-free generator of the invention is now described. Permanent magnet trains **2** and **2'** in ring forms are attached and fixed to respective left and right orbits **1** and **1'** provided relative to rotational axis **3** with a certain interval between them. Permanent magnet trains **2** and **2'** are fixed onto left and right orbits **1** and **1'** respectively such that the polarities on the outer peripheral surface of each magnet train relative to the rotational axis are alternately N poles and S poles. The permanent magnet trains are rotatable about the axis. Further, the facing polarities of respective permanent magnet train **2** and permanent magnet train **2'** relative to the direction of rotational axis **3** are arranged to be opposite.

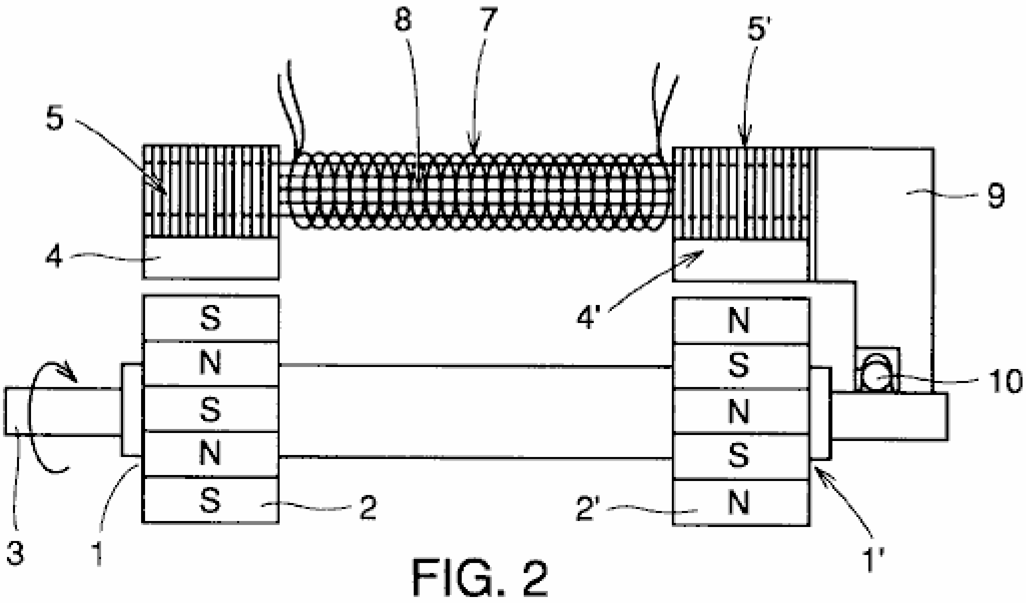

FIG. 2

As shown in **Fig.2**, rotational axis **3** and a case **9** are joined by a bearing **10** at a certain distance from the permanent magnet trains **2** and **2'**.

At a predetermined distance from permanent magnet trains **2** and **2'**, magnetic induction primary cores **4** and **4'** with respective coils wound around them are fixed to case **9**.

In addition, magnetic induction secondary cores **5** and **5'** each having two coupling holes **6** and **6'** formed therein are structured by stacking and coupling a plurality of thin cores attached and fixed to magnetic induction primary cores **4** and **4'** respectively and the secondary cores are attached and fixed to case **9**.

Magnetic induction tertiary cores **8** and **8'** are inserted respectively into coupling holes **6** and **6'** of magnetic induction secondary cores **5** and **5'** so as to couple magnetic induction secondary cores **5** and **5'** of each other.

Responsive coils **7** and **7'** are wound in opposite directions to each other around respective magnetic induction cores **8** and **8'**.

Fig.3 illustrates a structure formed of magnetic induction secondary cores **5** and **5'**, magnetic induction cores **8** and **8'** and responsive coils **7** and **7'** viewed in the direction perpendicular to rotational axis **3**.

As explained above, the directions of windings of responsive coils **7** and **7'** are respectively opposite to each other around magnetic induction cores **8** and **8'** which couple magnetic induction secondary cores **5** and **5'**.

In the structure described in conjunction with **Fig.1**, **Fig.2** and **Fig.3**, when rotational axis **3** of the generator rotates, permanent magnetic trains **2** and **2'** accordingly rotate to generate magnetically sensitive currents (electromagnetically induced current) in responsive coils **7** and **7'** and the current thus produced can be drawn out for use.

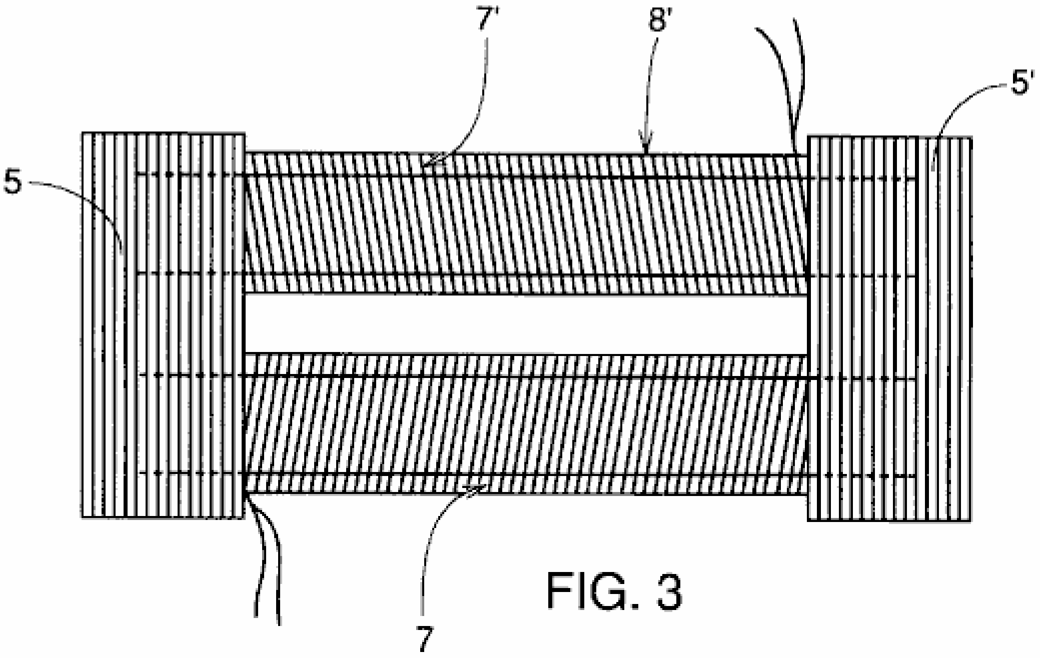

FIG. 3

As shown in **Fig.3**, the coils are wound about magnetic induction cores **8** and **8'** respectively in the opposite directions in the generator of the present invention, and the directions of the magnetic fields generated by the flow of the induced currents are arranged such that the N pole and S pole alternately occurs around rotational axis **3**.

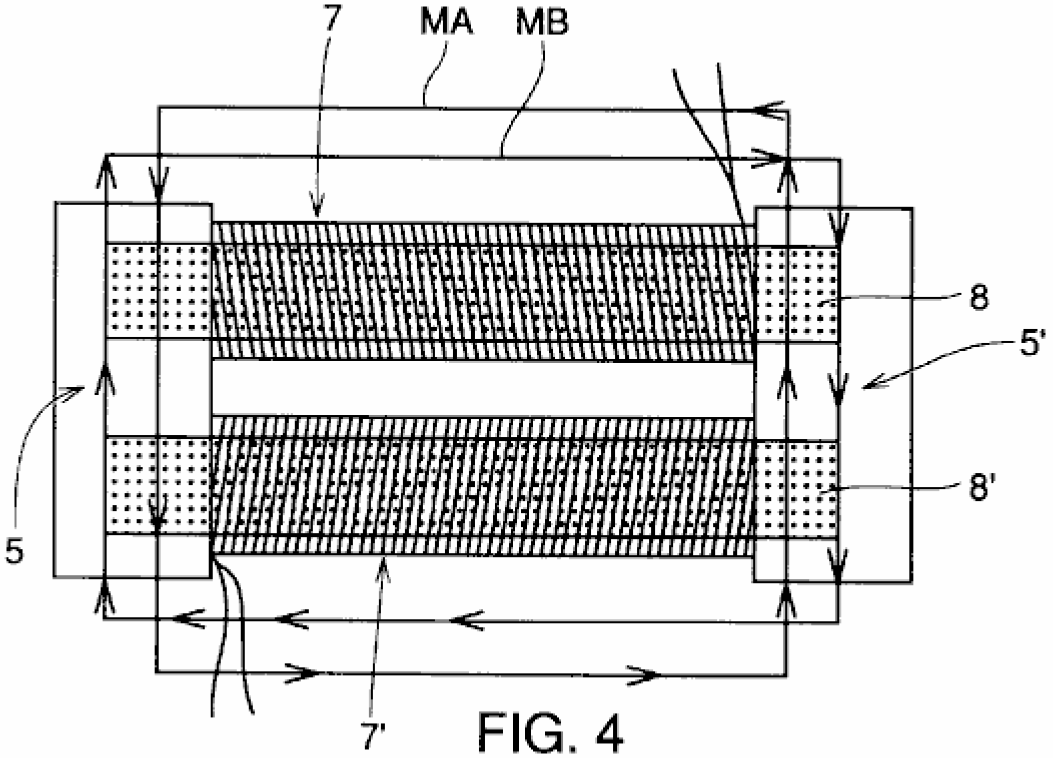

FIG. 4

Fig.4 illustrates magnetic fields induced in a set of magnetic induction secondary cores **5** and **5'**, magnetic induction cores **8** and **8'** and responsive coils **7** and **7'**.

At iron strips on both ends of respective magnetic induction secondary cores **5** and **5'**, a reverse current magnetic field is generated by responsive coil **7** upon the rotation of N and S poles of permanent magnet trains **2** and **2'** is in the direction of **MA** shown in **Fig.4**, for example, while a reverse current magnetic field generated by responsive coil **7** is in the direction of **MB** in **Fig.4**. Consequently, the reverse magnetic fields generated by the flow of currents cancel each other. The cores are formed of a plurality of iron strips in order to eliminate heat generated by eddy currents.

The magnetic field of the rotor thus has no dependence on the flow of currents, the load caused by the induced magnetisation phenomenon disappears, and energy of movement necessary for rotation against the mechanical primary load of the rotor itself is applied to the rotor.

At this time, a magnetic circuit including magnetic induction secondary cores **5** and **5'** and magnetic induction tertiary cores **8** and **8'** should be shaped into ".quadrature." form. If the circuit does not structured as ".quadrature." form, a part of the reverse magnetic field functions as electrical force which hinders the rotational force of the rotor.

Further, permanent magnet trains **2** and **2'** of the rotor are arranged to have opposite poles to each other on the left and right sides as shown in **Fig.2** so as to constitute the flow of magnetic flux. Each rotor has alternately arranged magnets, for example, eight poles are provided to enhance the generator efficiency.

More detailed description of the operational principle is given now. When the rotor in **Fig.1** rotates once, S and N poles of permanent magnets **2** and **2'** attached to the periphery of the rotor successively supply magnetic fields to induction primary cores **4** above, and magnetic field is accordingly generated in a path from one orbit of the rotor along induction primary core **4**, induction secondary core **5**, induction tertiary core **8**, induction secondary core **5'**, induction primary core **4'** to the other orbit of the rotor as shown in **Fig.2**.

Accordingly, current flows in the coils affected by this electric field to generate electric power. For example, if the generated power is used as generated output for switching on an electric light or for using it as motive energy, the current flowing through the coils generates the reverse magnetic fields. However, this reverse magnetic fields do not influence permanent magnets **2** and **2'** attached to the rotor in **Fig.2** since the reverse magnetic fields of the same magnitude respectively of S and N or N and S on both ends of magnetic induction secondary cores **5** and **5'** cancel out each other as shown in **Fig.4**. Because of this, the rotor is in a no-load state in which any resistance except the weight of the rotor itself and dynamic resistance is not exerted on the rotor.

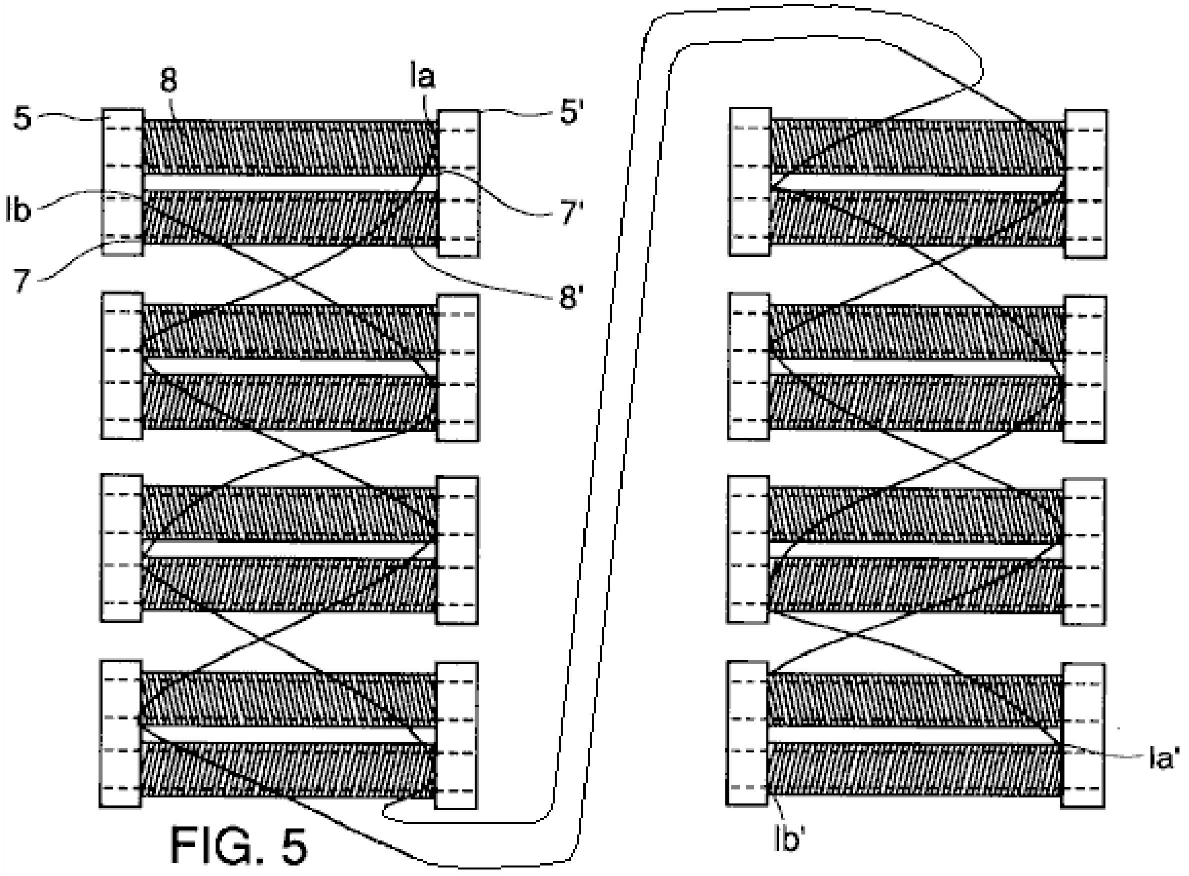

FIG. 5

Fig.5 illustrates a manner of connecting magnetically responsive coils **7** and **7'** wound around magnetic induction tertiary cores **8** and **8'** with eight poles.

Referring to **Fig.5**, according to a method of connecting magnetically responsive coils **7** and **7'** , line **1a1** of responsive coil **7'** (one drawn-out line of the wire coiled around a first magnetic induction core **8**) is connected to line **1a2'** (one drawn-out line of the wire coiled around a second magnetic induction core **8**), and then line **1a2** (the other drawn-out line of the wire coiled around a second magnetic induction core **8**) is connected to line **1a3'**, and subsequently lines **1a** and **1a'** are connected successively in zigzag manner to allow current to flow. Further, responsive coil **7** is arranged to connect lines represented by **1b1** in zigzag manner such that lines **1b** and **1b'** are successively connected. In this way, lines **1b**, **1b'** and lines **1a** and **1a'** of respective magnetically responsive coils **7** and **7'** are connected. As a whole, total four electric wires are drawn out for use.

When electric power is to be generated according to the present invention as described above, specifically, a closed circuit is formed by responsive coils **7** and **7'**, electric currents are induced in responsive coils **7** and **7'** wound around the magnetic induction cores of the generator, and the induced magnetic fields produced respectively by responsive coils **7** and **7'** could cause a great load which interferes the rotational force of the rotor. However, as shown in **Fig.4**, the direction of convolution of one coil **7** is opposite to that of the other coil **7'** so that the magnetic force generated by the reverse currents (induced currents) in responsive coils **7** and **7'** wound around magnetic induction core **4** is not transmitted to magnetic induction cores **8** and **8** accordingly no reverse magnetic force is transmitted to permanent magnets **2** and **2'**.

Therefore, each time the N poles and S poles alternate with each other because of the alternation of permanent magnets **2** and **2'** shown in **Fig.2**, the reverse magnetic forces in the right and left direction opposite to the direction of arrows denoted by **MA** and **MB** completely disappear as shown in **Fig.4**. Consequently, the reverse magnetic forces caused by the reverse currents are not influenced by permanent magnets **2** and **2'** and accordingly no load except the mechanical primary load is exerted on the generator of the invention.

As discussed above, the load-free generator of the present invention, secondary load except mechanical load of the generator, i.e. the load caused by the reverse currents flowing through the responsive coils can be nulled. With regard to this load-free generator, even if 100% of the current generated by magnetic induction (electromagnetic induction) is used, the magnetic secondary load due to the reverse currents except the mechanical primary load does not serve as load.

Although the number of poles of the rotor is described as **8** in the above description, the present invention is not limited to such a structure, and the invention can exhibit its effect when the smaller or greater number of poles is applied.

Further, although the magnet of the rotor is described as the permanent magnet in the above structure, the invention is not limited to such a case and the magnet of the rotor may be an electromagnet, for example.

In addition, although the description above is applied to the structure of the rotating-field type generator, the generator may be of the rotating-armature type.

EXPERIMENTAL EXAMPLE

More detailed description of the generator of the present invention is hereinafter given based on specific experimental examples of the invention.

The generator of the present invention and a conventional generator were used to measure the electric power production efficiency and the amount of load and compare the resultant measurements.

EXPERIMENTAL EXAMPLE 1

A 12-pole alternating current (AC) generator for battery charging was used, and the electricity output and the load when 50% of the electricity output was used as well as those when 100% of the electricity output was used were measured. The generator above is a single-phase AC motor and the employed power source was 220V, with 1750 rpm and the efficiency of 60%. The result of measurement using power of a motor of 0.5HP and ampere .times.volt gauge is shown in **Table 1**.

EXPERIMENTAL EXAMPLE 2

Measurement was done under the same conditions as those of experimental example 1 and a generator used was the one which was made according to the present invention to have the same conditions as those of the product of the existing model above. The result of measurement using ampere x volt gauge is shown in **Table 1**.

Table 1

	50% Electricity Used		100% Electricity Used	
Type of Generator	Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)
Conventional:	100	221	14	347
This invention:	100	220	183	200

(electricity output and load amount of the alternating current generators when 50% and 100% of the electricity were used)

From the result of Experimental Example 1 above, the reason for the remarkable reduction of the electricity output when the electricity consumption was 100% relative to the electricity consumption of 50% in the conventional generator is considered to be the significant increase of the repulsive load exerted on the generator when 100% of the electricity is used.

On the other hand, in the generator of the present invention, there was no appreciable difference in the amount of load between those cases in which 50% of the electricity was used and 100% thereof was used respectively. Rather, the amount of load slightly decreased (approximately 20W) when 100% of the electricity was used. In view of this, it can be understood that the amount of generated electric power of the generator of the present invention is approximately doubled as the electricity consumption increases, which is different from the conventional generator producing electric power which sharply decreases when the electricity consumption increases.

In conclusion, the amount of load above is supposed to be numerical value relative to the mechanical load of the generator as described above. Any secondary load except this, i.e. load due to the reverse currents generated in the armature responsive coils can be confirmed as zero.

EXPERIMENTAL EXAMPLE 3

12V direct current (DC) generators having similar conditions to those in experimental example 1 were used to make measurement under the same conditions (efficiency 80%). The result of the measurement is presented below.

Table 2

	50% Electricity Used		100% Electricity Used	
Type of Generator	Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)
Conventional:	103	290	21	298
This invention:	107	282	236	272

(electricity output and load amount of the alternating current generators when 50% and 100% of the electricity were used)

The DC generator has higher efficiency (80%) than that of the AC generator, while use of the brush increases the cost of the DC generator. When 100% of the electricity was used, the amount of load slightly decreased which was similar to the result shown in Table 1 and the electricity output was approximately at least 2.2 times that when 50% of the electricity was used.

EXPERIMENTAL EXAMPLE 4

A 220V single-phase alternating current (AC) generator (0.5HP) having similar conditions to those in experimental example 1 was used, and the rotation per minute (rpm) was changed to make measurement under the condition of 100% consumption of the generated electricity. The result of measurement is illustrated in the following **Table 3**.

Table 3

1750 rpm		3600 rpm		5100 rpm	
Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)
130	160	210	228	307	342

(amounts of generated electric power and load when the rotation per minute of the generator of the present invention was varied)

As shown in **Table 3** above, as the rotation per minute (rpm) increases as from 1750, 3600 to 5100, the amount of electric power increases respectively from 130, 210 to 307W and consequently the difference between the amount of generated electric power and the amount of load decreases to cause relative decrease of the amount of load as the rotation per minute (rpm) increases.

EXPERIMENTAL EXAMPLE 5

Measurement was done by changing the number of N and S poles of the permanent magnets of the invention under the same conditions as those of experimental example 1 and under the condition that 100% of the generated electricity was used.

The result of the measurement is illustrated below.

Table 4

2 poles		4 poles		8 poles	
Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)	Electricity Output (Watts)	Amount of Load (Watts)
80	152	130	200	265	296

(amounts of generated electric power and load when the number of poles of the permanent magnets of the generator of the invention was changed)

From **Table 4** above, it can be understood that as the number of poles increases, both of the amounts of generated electric power and load increase. However, the ratio of the amount of generated electric power to the amount of load monotonously increases. In the table above, in terms of the amount of load, only the mechanical primary load is exerted and electrical secondary is not exerted.

The increase of the number of poles causes increase, by the number of increased poles, in the number of lines of magnetic flux which coils traverse, and accordingly the electromotive force increases to increase the amount of generated electric power. On the other hand, the amount of mechanical load has a constant value regardless of the increase of the number of poles, so that the mechanical load amount relatively decreases to reduce the difference between the amount of load and the amount of generated electric power.

Detailed description of the present invention which has been given above is just for the purpose of presenting example and illustration, not for limitation. It will dearly be appreciated that the spirit and scope of the invention will be limited only by the attached scope of claims.

Patent Application US 20020125774 6th March 2002 Inventor: Alberto Molina-Martinez

CONTINUOUS ELECTRICAL GENERATOR

This patent application shows the details of a device which it is claimed, can produce sufficient electricity to power both itself and external loads. It also has no moving parts.

ABSTRACT

A stationary cylindrical electromagnetic core, made of one piece thin laminations stacked to desired height, having closed slots radially distributed, where two three-phase winding arrangements are placed together in the same slots, one to the centre, one to the exterior, for the purpose of creating a rotational electromagnetic field by temporarily applying a three-phase current to one of the windings, and by this means, inducting a voltage on the second one, in such a way that the outgoing energy is a lot greater than the input. A return will feedback the system and the temporary source is then disconnected. The generator will run by itself indefinitely, permanently generating a great excess of energy.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates generally to electrical power generating systems. More specifically, the present invention relates to self-feeding electrical power generating units.

2. Description of Related Art

Since Nikola Tesla invented and patented his Polyphase System for Generators, Induction Motors and Transformers, no essential improvement has been made in the field. The generators would produce the polyphase voltages and currents by means of mechanical rotational movement in order to force a magnetic field to rotate across the generator's radially spaced windings. The basis of the induction motor system was to create an electro-magnetically rotating field, instead of a mechanically rotated magnetic field, which would induce voltages and currents to generate electromotive forces usable as mechanical energy or power. Finally, the transformers would manipulate the voltages and currents to make them feasible for their use and transmission for long distances.

In all present Electric Generators a small amount of energy, normally less than one percent of the outgoing power in big generators, is used to excite the mechanically rotated electromagnetic poles that will induce voltages and currents in conductors having a relative speed or movement between them and the polar masses.

The rest of the energy used in the process of obtaining electricity, is needed to move the masses and to overcome the losses of the system: mechanical losses; friction losses; brushes losses, windage losses; armature reaction losses; air gap losses; synchronous reactance losses; eddy current losses; hysteresis losses, all of which, in conjunction, are responsible for the excess in power input (mechanical power) required to generate always smaller amounts of electric power.

SUMMARY OF THE INVENTION

The **C**ontinuous **E**lectrical **G**enerator consists of a stationary cylindrical electromagnetic core made of one piece thin laminations stacked together to form a cylinder, where two three-phase windings arrangements are placed in the same slots not having any physical relative speed or displacement between them. When one of the windings is connected to a temporary three-phase source, an electromagnetic rotating field is created, and the field this way created will cut the stationary coils of the second winding, inducting voltages and currents. In the same way and extent as in common generators, about one percent or less of the outgoing power will be needed to keep the rotational magnetic field excited.

In the **C**ontinuous **E**lectrical **G**enerator there are no mechanical losses; friction losses; brush losses; windage losses; armature reaction losses; or air gap losses, because there is not any movement of any kind. There are: synchronous reactance losses, eddy current losses and hysteresis losses, which are inherent to the design, construction and the materials of the generator, but in the same extent as in common generators.

One percent or less of the total energy produced by present electric generators goes to create their own magnetic field; a mechanical energy that exceeds the total output of present generators is used to make them rotate in the process of extracting electrical currents from them. In the **C**ontinuous **E**lectrical **G**enerator there is no need for movement since the field is in fact already rotating electro-magnetically, so all that mechanical energy will not be needed. Under similar conditions of exciting currents, core mass and windings design, the **C**ontinuous **E**lectrical **G**enerator is significantly more efficient than present generators, which also means that it can produce significantly more than the energy it needs to operate. The **C**ontinuous **E**lectrical **G**enerator can feedback the system, the temporary source may be disconnected and the Generator will run indefinitely.

As with any other generator, the **C**ontinuous **E**lectrical **G**enerator may excite its own electromagnetic field with a minimum part of the electrical energy produced. The **C**ontinuous **E**lectrical **G**enerator only needs to be started up by connecting its inducting three-phase windings to a three-phase external source for an instant, and then to be disconnected, to start the system as described herein. Then, disconnected, it will run indefinitely generating a great excess of electric power to the extent of its design.

The **C**ontinuous **E**lectrical **G**enerator can be designed and calculated with all mathematical formulas in use today to design and calculate electrical generators and motors. It complies with all of the laws and parameters used to calculate electrical induction and generation of electricity today.

Except for the Law of Conservation of Energy, which, by itself, is not a mathematical equation but a theoretical concept and by the same reason does not have any role in the mathematical calculation of an electrical generator of any type, the **C**ontinuous **E**lectrical **G**enerator complies with all the Laws of Physics and Electrical Engineering. The **C**ontinuous **E**lectrical **G**enerator obligates us to review the Law of Conservation of Energy. In my personal belief, the electricity has never come from the mechanical energy that we put into a machine to move the masses against all oppositions. The mechanical system is actually providing the path for the condensation of electricity. The **C**ontinuous **E**lectrical **G**enerator provides a more efficient path for the electricity.

FIG. 9

DETAILED DESCRIPTION OF THE INVENTION

The present invention is a Continuous and Autonomous Electrical Generator, capable of producing more energy than it needs to operate, and which provides itself the energy needed to operate. The basic idea consists in the induction of electric voltages and currents without any physical movement by the use of a rotational magnetic field created by a three-phase stator connected temporarily to a three-phase source, and placing stationary conductors on the path of said rotational magnetic field, eliminating the need of mechanical forces.

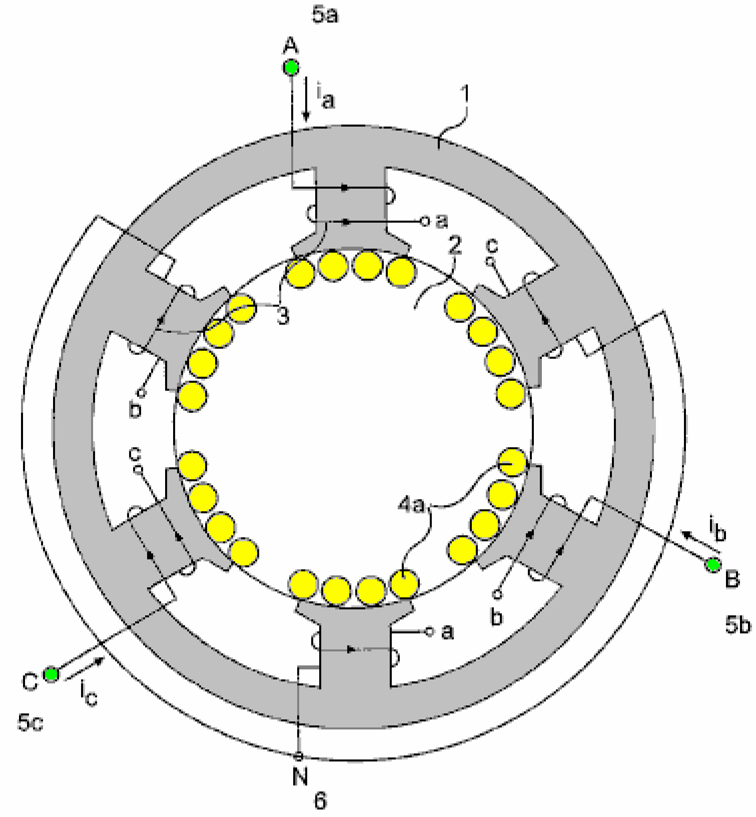

FIG. 1

The basic system can be observed in **Fig.1**, which shows one embodiment of the present invention. There is a stationary ferromagnetic core **1** with a three-phase inducting windings **3**, spaced 120 degrees and connected in Y **6** in order to provide a rotating electromagnetic field, when a three-phase voltage is applied; for the case, a two-pole arrangement. Inside this core **1** there is a second stationary ferromagnetic core **2**, with no space between them, this is, with no air-gap. This second core **2** has also a three-phase stationary winding arrangement (**4a** in **Fig.4b** and **4b** in **Fig.2**), aligned as shown in **Fig.1** and **Fig.2** with the external core inducting windings **3**. There is not any movement between the two cores, since there is no air-gap between them.

There is no shaft on either core since these are not rotating cores. The two cores can be made of stacked insulated laminations or of insulated compressed and bonded ferromagnetic powder. The system works either way, inducting three-phase voltages and currents on the stationary conductors **4a** of the internal windings **4b**, applying three-phase currents to terminals **A 5a**, **B 5b** and **C 5c** of the external windings **3**; or inducting three-phase voltages and currents on the external windings **3**, by applying three-phase currents to the terminals **T1 7a**, **T2 7b** and **T3 7c**, of the internal windings **4b**. When a three-phase voltage is applied to terminals **A 5a**, **B 5b** and **C 5c**, the currents will have the same magnitude, but will be displaced in time by an angle of 120 degrees. These currents produce magneto motive-forces, which, in turn, create a rotational magnetic flux. The arrangements may vary widely as they occur with present alternators and three-phase motors, but the basics remain the same, a stationary but electro-magnetically rotating magnetic field, inducting voltages and currents on the stationary conductors placed on the path of said rotating magnetic field. The diagram is showing a two-pole arrangement for both windings, but many other arrangements may be used, as in common generators and motors.

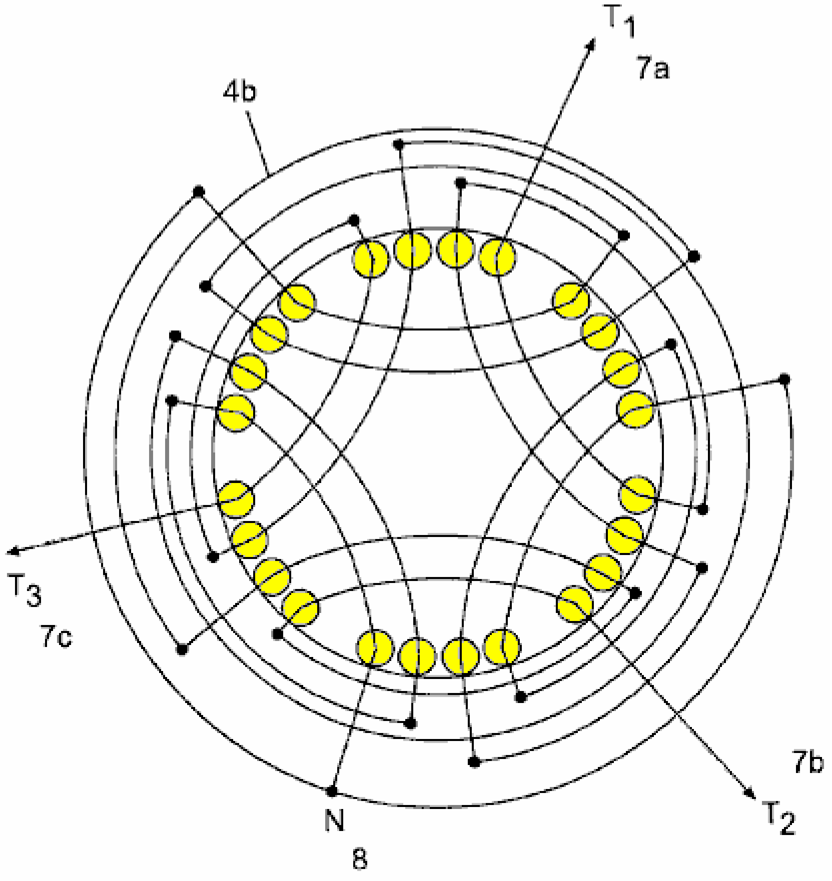

FIG. 2

Fig.2 shows the three-phase arrangement of the internal winding **4b** which has provided, in practice, symmetrical voltages and currents, due to a space angle of 120 degrees. It is similar to a two-pole arrangement. Many other three-phase or poly-phase arrangements may be used. Wherever a conductor is crossed by a rotational magnetic field, a voltage will be induced across its terminals. The interconnections depend on the use that we will give to the system. In this case, we will have a three-phase voltage in terminals **T1 7a, T2 7b** and **T3 7c** and a neutral **8**. The outgoing voltage depends on the density of the rotational magnetic flux, the number of turns of the conductor, the frequency (instead of the speed) and the length of the conductor crossed by the field, as in any other generator.

Fig.3 shows an alternate embodiment of the present invention in which the generator is made from multiple one-piece laminations **9**, stacked as a cylinder to the desired height. This embodiment can also be made of a one-piece block of compressed and bonded insulated ferromagnetic powder. The same slot **10** will accommodate the internal **4a/4b** and the external windings **3**, that is, the inducting and the induced windings (see **Fig.5**). In this case, a 24-slot laminate is shown, but the number of slots may vary widely according to the design and needs.

Fig.4 shows a two-piece single laminate for another alternate embodiment of the present invention. For practical effects the lamination can be divided into two pieces **9a, 9b**, as shown, to facilitate the insertion of the coils. Then, they are solidly assembled without separation between them, as if they were only one piece.

The laminates described above may be constructed with thin (0.15 mm thick or less) insulated laminations **9** or **9a** and **9b** of a high magnetic permeability material and low hysteresis losses such as Hiperco 50A, or similar, to reduce losses or with compressed electrically isolated ferromagnetic powder, which has lower eddy current losses and also may have low hysteresis losses, which can make the generator highly efficient.

OPERATING THE GENERATOR

The **C**ontinuous **E**lectrical **G**enerator as described and shown in the following drawings is designed and calculated to produce a strong rotating electromagnetic field with low exciting currents. By using a laminated material, such as the said Hiperco 50A, we can achieve rotating magnetic fields above two Teslas, since there are no air gap losses, mechanical losses, windage losses, armature reaction losses, etc. as said before. This may be obtained by applying a temporary three-phase current to the terminals **A**, **B** and **C 12** of the inducting coils **13, 14** and **15** (**5a, 5b** and **5c** in **Fig.1**), spaced 120 degrees from each other (see **Fig.5**).

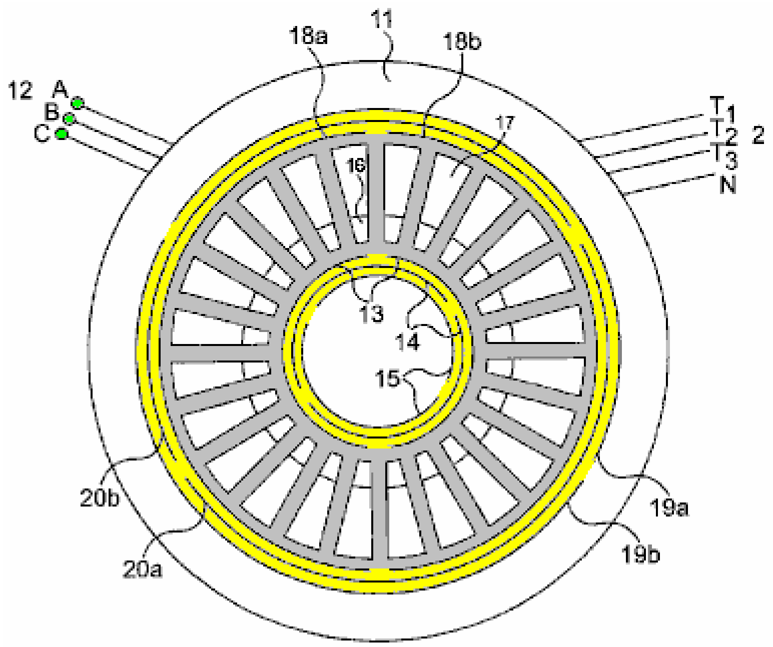

FIG. 5

Fig.5 shows the spatial distribution of the inducting windings **13, 14** and **15**, as well as the induced windings **18a, 18b, 19a, 19b, 20a** and **20b**. Both, the inducting and the induced windings are placed in the same slots **10** or **16** and **17**, with similar arrangements. Even though the system works in both directions, the better configuration seems to be to place the inducting windings **13, 14** and **15**, to the centre and the induced windings **18a, 18b, 19a, 19b, 20a** and **20b**, to the exterior, since small windings will be needed to induce a very strong rotational magnetic field, due to the small losses involved in the process, and in exchange, bigger and powerful windings will be needed to extract all the energy that the system will provide. Both windings are connected in Y (not shown), but they can be connected in different ways, as any other generator. These arrangements are equivalent to the arrangements shown for the embodiment in **Fig.1** and **Fig.2**.

The inducting coils **13, 14** and **15** are designed and calculated so that the generator may be started with common three-phase lines voltages (230 Volts 60 Hz per phase, for example). If the local lines voltages are not appropriate, we can control the voltage to the designed level by means of a three-phase variable transformer, an electronic variator or inverter etc. Once we have such strong magnetic field rotating and crossing the stationary induced coils **18a, 18b, 19a, 19b, 20a** and **20b**, a three-phase voltage will be induced across terminals **T1, T2, T3** and **N 21** in proportion to the magnetic flux density, the number of turns in the coils, the frequency used (instead of the speed), the length of the conductors cut by the rotating field, as in any other alternator. We can connect, as we desire in Y or delta, etc., as in any other alternator or generator. The outgoing currents will be three-phase currents (or poly-phase currents depending on the arrangement) and we can have a neutral **21** if we are using a Y connection, as in any other alternator.

The outgoing alternate voltages and currents are perfect sinusoidal waves, perfectly spaced in time, and totally symmetrical. The voltages and currents obtained by this method are usable in any conventional manner. Any voltage can be produced, depending on the design.

Fig.6 shows the magnetic flux pattern produced by the three-phase inducting windings **13, 14** and **15**. This pattern is similar to the pattern of an induction motor's stators. Since there is no air gap; the whole path for the magnetic flux is homogeneous with no change in materials. The core is made of thin insulated laminations of a high magnetic permeability and low hysteresis loss material; eddy current losses are minimal due to the thin lamination. There are no counter fluxes or armature reactions thus the magnetic flux may be near to saturation with a small exciting current or input energy. Due to the time differential between the three phases and the spatial distribution of the inducting windings, a rotational magnetic field will be created in the core, as shown in **Fig.7**.

Once the generator is started, a small part of the energy obtained is sent back (**Fig.8** and **Fig.9**) to feed the inducting coils **3** (in **Fig.1**) or **13, 14** and **15** (in **Fig.5**), as in any other auto-excited alternator or generator. Of course voltages and phases should be perfectly identical and aligned, and if necessary the feedback voltages should be controlled and handled by means of variable transformers, electronic variators, phase shifters (to align phases) or other type of voltage or phase controllers.

One possible method consists of the use of an electronic converter or variator **25** which initially converts two or three lines of alternating current **24** to direct current by an electronic rectifier **26** and then, electronically, converts the direct current **27** to three-phase current **28** to supply three-phase currents spaced in time 120 degrees for the electromagnetic fields **A, B** and **C 3**. Some variators or converters can accept two lines of voltage, while others will accept only a three-phase line voltage. This embodiment uses a variator of 3 kVA that accepts two 220-volt lines.

The rotational magnetic field created by the currents going through the inducting three-phase windings **13**, **14** and **15**, will induce a voltage across the terminals **T1, T2, T3, N, 29** (**7a, 7b, 7c, 8** in **Fig.2**). Then, from the outgoing current lines **29**, a derivation is made **30** to feed back the system, converting the feed back alternate currents, by means of electronic diode rectifiers **31**, to direct current **32** and then feed back the electronic converter or variator **25** to the DC terminals of the electronic rectifier **26** (See **Fig.8**). Once the feedback is connected, the **C**ontinuous **E**lectrical **G**enerator may be disconnected from the temporary source **24**, and will continue generating electric energy indefinitely.

In **Fig.9**, an alternate embodiment of the **C**ontinuous **E**lectrical **G**enerator can be observed. The basic principles remain the same as for the embodiment described above and shown in **Fig.1** and **Fig.2**. The basic differences are in the shape of the laminations and the physical distribution of the windings, as discussed and shown previously. A variation of the feedback, using a variable and shifting transformers is also shown.

The ferromagnetic core **11** is made of one-piece laminates **9** as shown in **Fig.3** (or two for convenience **9a**, **9b** as shown in **Fig.4**) stacked to the desired height. The slots **10**, as indicated before, will accommodate both the inducting **13, 14** and **15** and the induced **18a-b, 19a-b** and **20a-b** windings in the same slot **10** or **16** and **17**. The incoming three phase lines **12** feed the inducting three-phase windings **13, 14** and **15**. They are fed, initially by the temporary source **33** in the first instance, and by the three-phase return **34** once the generator is running by itself.

The inducting windings **13, 14** and **15** have a two-pole arrangement, but many other three-phase or poly-phase arrangements can be made to obtain an electromagnetic rotating field. These windings are connected in Y (not shown) in the same way shown for the embodiment shown in **Fig.1**, **Fig.2** and **Fig.8**, but may be connected in many different ways. The inducting windings **13, 14** and **15** are located in the internal portion **16** of the slot **10** (**Fig.5**).

The induced windings **18a-b**, **19a-b** and **20a-b** have a two-pole arrangement, exactly equal to the arrangement for the inducting windings **13, 14** and **15**, but many other arrangements can be made depending on the design and the needs. The induced windings must be calculated in a way that the generator will have the lowest possible synchronous reactance and resistance. In this way, most of the outgoing power will go to the charge instead of staying to overcome the internal impedance. These windings are connected in Y to generate a neutral **21**, in the same way shown in the embodiment of the present invention shown in **Fig.2**, but may be connected in different ways according to the needs. The induced windings **18a-b, 19a-b** and **20a-b** are located in the external portion **17** of the slot **10**.

The outgoing three-phase and neutral lines **21** come from the induced windings **18a-b, 19a-b** and **20a-b**. The rotational magnetic field created in the core (see **Fig.6** & **Fig.7**) by the inducting windings **13, 14** and **15**, induces a voltage across the terminals **T1, T2** and **T3**, plus a neutral, **29**. From each of the three-phase outgoing lines **21**, a return derivation **34** is made to feedback the system.

The temporary three-phase source **33** is temporarily connected to terminals **A, B** and **C 12**. The **C**ontinuous **E**lectrical **G**enerator must be started with an external three-phase source for an instant, and then disconnected.

Even though the return lines voltage can be calculated and obtained precisely by tabbing the induced windings at the voltage required by the inducting windings (according to the design), it may be convenient to place a three-phase variable transformer or other type of voltage controller **35** in the middle for more precise adjustment of the return voltage.

Placed after the variable transformer **35**, the three-phase shifting transformer **36** will correct and align any phase shift in the voltage and currents angles, before the return is connected. This system functions similarly to the system shown in **Fig.8** which uses a variator or a converter **25**.

Once the voltage and phases are aligned with the temporary source **33**, the return lines **34** are connected to the incoming lines **A, B** and **C 12** at feedback connection **37** and the temporary source **33** is then disconnected. The **C**ontinuous **E**lectrical **G**enerator will remain working indefinitely without any external source of energy, providing a great excess of energy permanently.

The outgoing electric energy provided by this system has been used to produce light and heat, run poly-phase motors, generate usable mono-phase and poly-phase voltages and currents, transform voltages and currents by means of transformers, convert the alternate outgoing poly-phase currents to direct current, as well as for other uses. The electricity obtained by the means described is as versatile and perfect as the electricity obtained today with common electric generators. But the **C**ontinuous **E**lectrical **G**enerator is autonomous and does not depend on any other source of energy but itself once it is running; may be carried anywhere with no limitations; it can be constructed in any size and provides any amount of electricity indefinitely, according to the design.

The **C**ontinuous **E**lectrical **G**enerator is and will be a very simple machine. The keystones of the systems reside in the ultra-low losses of a non-movement generation system, and in a very low synchronous reactance design.

The induced windings must be calculated in a way that the generator may have the lowest possible synchronous reactance and resistance. In this way, most of the outgoing power will go to the charge instead of staying to overcome the internal impedance.

Patent Application US 3,766,094 20th September 1971 Inventor: Michael Ognyanov

SEMICONDUCTOR COMPOSITIONS

This patent application shows the details of a device which it is claimed, can produce electricity via a solid-state oscillator. It should be noted that while construction details are provided which imply that the inventor constructed and tested several of these devices, this is only an application and not a granted patent.

ABSTRACT

A resonance oscillator electric power pack for operating a flash lamp, for example, or other electrically operated device, operates without moving mechanical parts or electrolytic action. The power pack is contained in a cylindrical metal envelope and in a preferred embodiment, is coupled to a relaxation oscillator and an incandescent lamp. Within the envelope, and insulated from it, is a semiconductor tablet having a metal base connected to the external circuit. A metal probe makes contact with a point on the semiconductor tablet and with a cylindrical ferrite rod, axially aligned with the envelope. Wound about the ferrite rod, are concentric helical coils designated as a ‘primary’ with many turns, and a ‘secondary’ with fewer turns than the primary.

One end of the primary coil is connected to the probe and the other end is connected to the secondary coil. the leads from the secondary coil are connected to the relaxation oscillator via an adjustable capacitor. Oscillation within the envelope is resonance amplified , and the induced voltage in the secondary coil is rectified for application to the relaxation oscillator and lamp. Selenium and germanium base semiconductor compositions including Te, Nd, Rb and Ga in varying proportions area used for the tablet.

BACKGROUND OF THE INVENTION

This is a continuation-in-part of my co-pending patent application Serial No. 77,452, filed 2nd October 1970, entitled “Electric Power Pack” now abandoned.

In many situations it is desirable to have a source of electric power which is not dependent on wires from a central generating station, and therefore, portable power supplies having no moving parts have been employed. typically, such portable power packs have been primary or secondary electrolytic cells which generate or store electrical energy for release by chemical action. Such batteries have a limited amount of contained energy and must often be replaced at frequent intervals to maintain equipment in operation.

Thus, as one example, flashing lights are commonly used along highways and other locations to warn of dangerous conditions. These flashing lights in remote locations are typically incandescent or gas-discharge lamps connected to some type of relaxation oscillator powered by a battery. The batteries employed in such blinking lights have a limited lifetime and must be periodically replaced, typically each 250 to 300 hours of operation. This involves a rather large labour cost in replacing the expended batteries with fresh ones and additional cost for primary cells or for recharging secondary cells. It is desirable to provide an electric power pack capable of providing a sufficient quantity of electrical energy over a prolonged period of time so that the requirement for periodic replacement of the electrolytic cells can be avoided. Such a power pack is valuable even if appreciably more expensive than batteries because of the greatly reduced labour costs required for periodic replacements.

BRIEF SUMMARY OF THE INVENTION

There is provided in practice of this invention according to a preferred embodiment, semiconductive compositions selected from the Group consisting of:

Selenium with, from 4.85% to 5.5% Tellurium, from 3.95% to 4.2% Germanium, from 2.85% to 3.2% Neodymium, and from 2.0% to 2.5% Gallium.

Selenium with, from 4.8% to 5.5% Tellurium, from 3.9% to 4.5% Germanium, from 2.9% to 3.5% Neodymium and from 4.5% to 5% Rubidium, and

Germanium with, from 4.75% to 5.5% Tellurium, from 4.0% to 4.5% Neodymium and from 5.5% to 7.0% Rubidium.

Fig.2 illustrates in longitudinal cross-section, the power pack of Fig.1

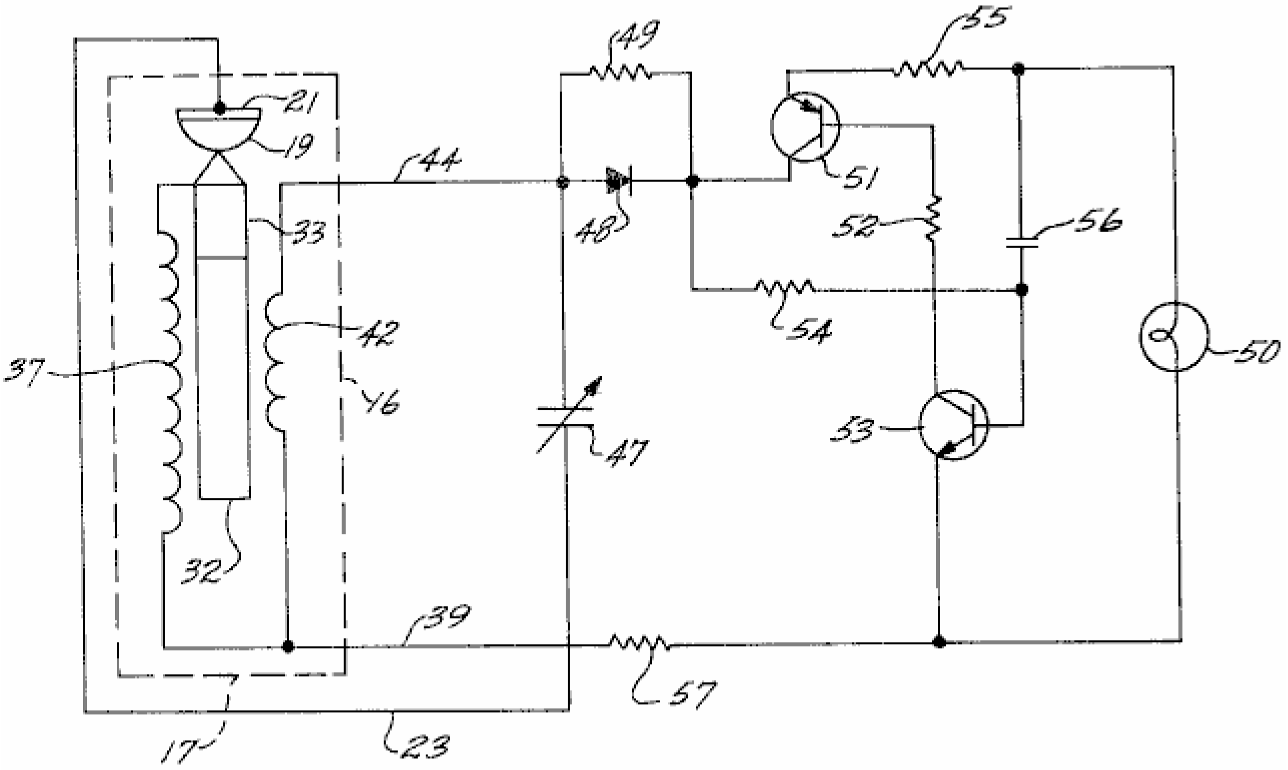

Fig.3 is an electric circuit diagram of the system.

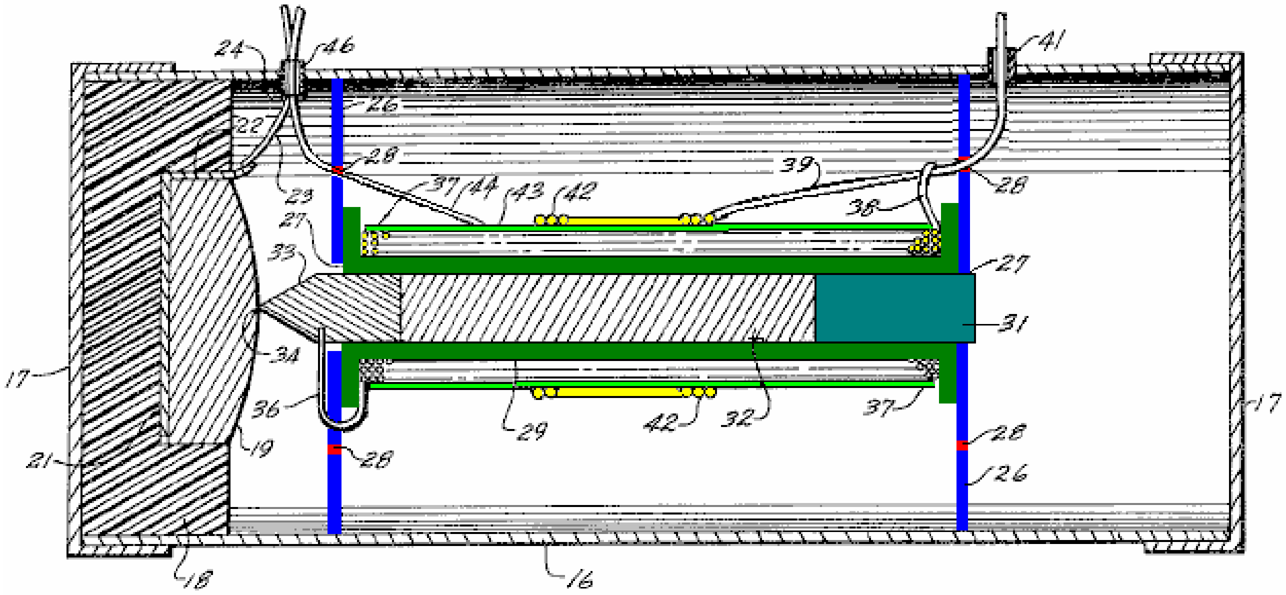
DESCRIPTION

Fig.1 illustrates schematically, a typical flashing lamp having a power supply constructed according to the principles of this invention. As illustrated in this preferred embodiment, an electric power pack **5**, is connected electrically to a relaxation oscillator circuit (shown only schematically) on a conventional printed-circuit board **6**.

The power pack **5** and the printed-circuit board are mounted in a metal box **7**, which has a transverse partial partition **8**, which creates two spaces, one for the power pack and the other for the printed-circuit board which is prevented from contacting the metal box by any convenient insulating mounting. Preferably, these components are potted in place in a conventional manner.

A cover **9**, having mounting lugs **10**, is riveted on to the box after assembly. A small terminal strip **11**, mounted on one side of the box **7**, provides electrical contacts for connection to a load such as an incandescent lamp (not shown in Fig.1). the lamp provides a flash of light when the relaxation oscillator switches. Although the described system is employed for a flashing lamp, it will be apparent that other loads may be powered by the invention.



In **Fig.2**, the electric power pack **10**, is illustrated in longitudinal cross-section and has dimensions as follows: These dimensions are provided by way of example for powering a conventional flashing lamp and it will be clear that other dimensions may be used for other applications. In particular, the dimensions may be enlarged in order to obtain higher power levels and different voltage or current levels. The power pack is comprised of a cylindrical metal tube **16**, having closely fitting metal caps **17** at each end, which are preferably sealed to the tube after the internal elements are inserted in place. The metal tube **16** and caps **17**, which are preferably of aluminium, thus form a closed conductive envelope, which in a typical embodiment, has an inside diameter of about 0.8 inch and a length of about 2.25 inches.

Mounted within one end of the envelope is a plastic cup **18**, the dimensions of which are not critical, however, a wall thickness of at least 1/16 inch is preferred. Mounted within the plastic cup **18** is a semiconductor tablet **19** having a flat base and somewhat domed opposite side. The composition of the semiconductor tablet **19** is set out in greater detail below. Typically, the semiconductor tablet has a mass of about 3.8 grams. A metal disc **21** is positioned beneath the base of the tablet **19** in the cup **18**, and is preferably adhesively bonded inside the cup. The metal disc is tightly fitted to the base of the tablet so that good electrical contact is obtained over a substantial area of the semiconductor.

An ear **22** on one edge of the disc is soldered to a wire **23**, which extends through a short insulating sleeve **24** which passes through a hole in the side of the metal envelope. The insulating sleeve **24** acts as a grommet and ensures that there is no damage to the insulation of wire **23** and subsequent accidental short circuiting between the wire and the metal envelope. Preferably, the insulating sleeve **24** is sealed with a small amount of plastic cement or the like, in order to maintain clean air within the cylindrical envelope. Two other openings for leads through the tube **16**, as mentioned below, are also preferably sealed to maintain cleanliness within the envelope.

A pair of circular metal discs **26**, are fitted inside tube **16** and are preferably cemented in place to prevent shifting. The two discs **26**, are equally spaced from the opposite ends of the envelope and are spaced apart by slightly more than 1.15 inches. Each of the discs has a central aperture **27**, and there is a plurality of holes **28**, extending through the disc in a circular array midway between the centre of the disc and it's periphery. The holes **28** are preferably in the size range of about 0.01 to 0.06 inch in diameter and there are 12 on each disc located at 30^0 intervals around the circle.

The two discs **26** divide the interior of the cylindrical envelope into three chambers, and the pattern of holes **28** provides communication between the chambers and affects the electrical properties of the cavity. It is believed that the pattern of holes affects the inductive coupling between the cavities inside the envelope and influences the oscillations in them.

Although an arrangement of 12 holes at 30^0 centres has been found particularly advantageous in the illustrated embodiment, it is found in other arrangements that a pattern of 20 holes at 18^0 centres or a pattern of 8 holes at 45^0 centres, provides optimum operation. In either case, the circle of holes **28** is midway between the centre and the periphery of the disc.

Mounted between the discs **26** is a plastic spool **29** which has an inside distance of 1.1 inches between its flanges. The plastic spool **29** preferably has relatively thin walls and an internal bore diameter of 1/8 inch. A plastic mounting plug **31**, is inserted through the central aperture **27** of the disc **26** farthest from the semiconductor table **19**, and into the bore of the spool **29.** The plastic plug **31** is preferably cemented to the disc **26** in order to hold the assembly together.

Also mounted inside the bore of spool **29** is a cylindrical ferrite core **32**, about 1/8 inch diameter and 3/4 inch long. Although a core of any magnetic ferrite is preferred, other ferromagnetic materials having similar properties can be used if desired. The core **32**, is in electrical contact with a metal probe **33** about 1/4 inch long. half of the length of the probe **33** is in the form of a cylinder positioned within the spool **29**, and the other half is in the form of a cone ending in a point **34** in contact with the domed surface of the semiconductor tablet **19** where it makes an electrical contact with the semiconductor in a relatively small point.

Electrical contact is also made with the probe **33** by a lead **36**, which passes through one of the holes **28** in the disc **26** nearer to the semiconductor tablet and thence to a primary coil **37**, wound on the plastic spool **29**. The primary coil **37** is in the form of 800 to 1000 turns wound along the length of the spool, and the lead **38** at the opposite end of the coil **37** is soldered to one of the external leads **39** of the power pack. This lead **39** proceeds through one of the holes **28** in the disc farthest from the semiconductor tablet **19**, and through an insulating sleeve **41** in the metal tube **16**.

The lead **39** is also connected to one end of a secondary coil **42** which is composed of 8 to 10 turns around the centre portion of the primary coil **37**. A thin insulating sheet **43** is provided between the primary and secondary coils. The other lead **44** from the secondary coil passes through one of the holes **28** in the disk nearer the semiconductor tablet and thence through an insulating sleeve **46** through the wall of the tube **16**.

Fig.3 illustrates schematically, the electrical circuit employing an electric power pack constructed according to the principles of this invention. At the left hand side of **Fig.3**, the arrangement of elements is illustrated in a combination of electrical schematic and mechanical position inside tube **16** for ready correlation with the embodiment illustrated in **Fig.2**. Thus, the semiconductor tablet **19**, probe **33** and ferrite core **32** are shown in both their mechanical and electrical arrangement, the core being inductively coupled to the coils **37** and **42**. The lead **23** from the metal base of the semiconductor tablet **19**, is connected to a variable capacitor **47**, the other side of which is connected to the lead **44** from the secondary coil **42**. The lead **44** is also connected to a rectifying diode **48** shunted by a high value resistor **49**.

It will be seen that the variable capacitor **47** is in a tank circuit with the inductive coils **37** and **42** which are coupled by the ferrite core **32**, and this circuit also includes the semiconductor tablet **19** to which point contact is made by the probe **33**. The mechanical and electrical arrangement of these elements provides a resonant cavity in which resonance occurs when the capacitor 47 is properly trimmed. The diode **48**, rectifies the oscillations in this circuit to provide a suitable DC for operating an incandescent lamp **50** or similar load.

The rectifying diode **48** is connected to a complementary-symmetry relaxation circuit for switching power to the load **50**. The diode is connected directly to the collector of a PNP transistor **51** which is in an inverted connection. the emitter of the PNP transistor is connected to one side of the load **50** by way of a timing resistor **55**. The base of the transistor **51** is connected by way of a resistor **52** and a capacitor **56** to the collector of an NPN transistor **53**, the emitter of which is connected to the other side of the load **50**. The base of the NPN transistor **53** is coupled to the diode by a resistor **54**. The emitter of the PNP transistor **51** is fed back to the base of the NPN transistor **53** by the resistor **55**. Current flow through the lamp **50** is also limited by a resistor **57** which couples one side of the lamp and the emitter of the NPN transistor **53** to the two coils **37** and **42** by way of the common lead **39**.

The electrical power pack is believed to operate due to a resonance amplification once an oscillation has been initiated in the cavity, particularly the central cavity between the discs **26**. This oscillation, which apparently rapidly reaches amplitudes sufficient for useful power, is then half-wave rectified for use by the diode **48**. With such an arrangement, a voltage level of several volts has been obtained, and power sufficient for intermittent operation of a lamp requiring about 170 to 250 milliwatts has been demonstrated. The resonant amplification is apparently due to the geometrical and electrical combination of the elements, which provide inductive coupling of components in a suitable resonant circuit. This amplification is also, at least in part, due to unique semiconductor properties in the tablet **19**, which has electronic properties due to a composition giving a unique atomic arrangement, the exact nature of which has not been measured.

The semiconductor tablet has electronic properties which are determined by it’s composition and three such semiconductors satisfactory for use in the combination have been identified. In two of these, the base semiconductor material is selenium provided with suitable dopant elements, and in the third, the base element is germanium, also suitably doped. The semiconductor tablets are made by melting and casting in an arrangement which gives a large crystal structure. It has not been found necessary to provide a selected crystal orientation in order to obtain the desired effects.

A preferred composition of the semiconductor includes about 5% by weight of tellurium, about 4% by weight of germanium, about 3% by weight of neodymium and about 4.7% by weight of rubidium, with the balance of the composition being selenium. Such a composition can be made by melting these materials together or by dissolving the materials in molten selenium.

Another highly advantageous composition has about 5% by weight of tellurium, about 4% by weight of germanium, about 3% by weight of neodymium, and about 2.24% by weight of gallium, with the balance being selenium. In order to make this composition, it is found desirable to add the very low melting point gallium in the form of gallium selenide rather than elemental gallium.

A third suitable composition has about 5% by weight of tellurium, about 4% by weight of neodymium, about 6% by weight of rubidium, with the balance being germanium. These preferred compositions are not absolute and it has been found that the level of dopant in the compositions can be varied within limits without significant loss of performance. Thus, it is found that the proportion of tellurium in the preferred composition can range from about 4.8% to about 5.5% by weight; the germanium can range from about 3.9% to 4.5% by weight; neodymium can range from about 2.9% to 3.5% by weight, and rubidium can vary from about 4.5% to 5.0% by weight. The balance of the preferred composition is selenium although it has also been found that nominal impurity levels can be tolerated and no great care is required in preventing minor contamination.

The other selenium base composition useful in practice of this invention can have a tellurium concentration in the range of from about 4.85% to 5.5% by weight, germanium in the range of from about 3.95% to 4.2% by weight, neodymium in the range of from about 2.85% to 3.2% by weight, and gallium in the range of from about 2.0% to 2.5% by weight. As in the preferred composition, the balance is selenium and nominal impurity levels can be tolerated. It is preferred to add the gallium in the form of gallium selenide rather than as elemental gallium with a corresponding decrease in the selenium used to make up the composition.

The above selenium base compositions are easier to make and less expensive than the germanium base composition and are therefore preferable for most applications. It is found that these are particularly suited for relatively small semiconductor tablets up to about 1 inch or a little less. For relatively large tablets, it is preferred to use the germanium base composition.

The germanium base composition has a tellurium level in the range of from about 4.75% to 5.5% by weight, neodymium in the range of from about 4.0% to 4.5% by weight, and rubidium in the range of from about 5.5% to 7.4% by weight. It is also found that it is of greater importance to maintain purity of the germanium base compositions than the selenium base compositions. Although the exact purity levels have not been ascertained, it is in excess of 99%.

It has been found that it is not necessary to have single crystals in the semiconductor tablets and any convenient grain size in excess of about 1 millimetre appears satisfactory. In the above compositions, when the recited ranges are exceeded, oscillation in the power pack drops off rapidly and may cease altogether.

The reasons that these compositions are satisfactory in the arrangement providing resonance amplification has not been determined with certainty. It is possible that the semiconductor serves as a source of electrons for providing an oscillating current in the circuit. This is, of course, combined with a relatively large area contact to one side of the semiconductor tablet, and a point contact on another area. Any resonant current in the coils wound on the ferrite rod, induces a varying magnetic field in the resonant cavity, and the electrical connection between the ferrite rod and the metal probe, provides a feedback of this oscillation to the semiconductor tablet.

it should particularly be noted that the oscillation in the circuit does not commence until it is initiated by an oscillating signal. In order to accomplish this, it is only necessary to apply a few millivolts of AC for a few seconds to the semiconductor tablet and the associated coils coupled to it. The initial signal applied to the base of the semiconductor tablet and the lead **39** is preferably in the frequency range of 5.8 to 18 Mhz and can be as high as 150 Mhz. Such a signal can be applied from any conventional source and no great care appears necessary to provide a single frequency signal or to eliminate noise. Once such energisation has been applied to the circuit and oscillations initiated, it does not appear to be necessary to apply such a signal again. This is apparently due to the feedback provided by the ferrite rod to the probe which makes contact with the semiconductor tablet.

Energy is, of course, dissipated in the lamp, or other utilisation device, as the combination operates. Such energy may come from deterioration of the semiconductor tablet as oscillations continue; however, if there is any such deterioration, it is sufficiently slow that a power source may be operated for many months without attendance. Such a source of energy may be augmented by ambient Radio Frequency radiation, coupled into the resonant cavity by the external leads. This is a surprising phenomenon because the leads are small compared to what would normally be considered an adequate antenna, and it is therefore postulated that stimulated amplification may also be a consequence of the unique electronic configuration of the semiconductors having the compositions specified above.

Although only one embodiment of electric power pack constructed according to principles of this invention has been described and illustrated here, many modifications and variations will be apparent to one skilled in the art. Thus, for example, a larger power pack may be axially arranged in a cylindrical container with various electronic elements arranged in the annular space. It is therefore to be understood that other configurations are included within the scope of the invention.

US Patent 3,890,548 June 17, 1975 Inventor: Edwin V. Gray snr.

PULSED CAPACITOR DISCHARGE ELECTRIC ENGINE

Please note that this is a re-worded extract from Edwin Gray's Patent 3,890,548. It describes his high voltage motor and the circuitry used to drive it. Please be aware that the underlying technology was developed by Marvin Cole and Edwin Gray did not understand it. Also, Edwin wanted at all costs to conceal any useful technology while getting patents to encourage investors, so please understand that this patent is not intended to tell you how to make a working system of this type.

SUMMARY OF THE INVENTION:

This invention relates to electric motors or engines, and more particularly to a new electric machine including electromagnetic poles in a stator configuration and electromagnetic poles in a rotor configuration, wherein in one form thereof, the rotor is rotatable within the stator configuration and where both are energised by capacitor discharges through rotor and stator electromagnets at the instant of the alignment of a rotor electromagnet with a stator electromagnet. The rotor electromagnet is repelled from the stator electromagnet by the discharge of the capacitor through the coils of both the rotor and stator electromagnets at the same instant.

In an exemplary rotary engine according to this invention, rotor electromagnets may be disposed 120 degrees apart on a central shaft and major stator electromagnets may be disposed 40 degrees apart in the motor housing about the stator periphery. Other combinations of rotor elements and stator elements may be utilised to increase torque or rate of rotation.

In another form, a second electromagnet is positioned to one side of each of the major stator electromagnets on a centreline 13.5 degrees from the centreline of the stator magnet, and these are excited in a predetermined pattern or sequence. Similarly, to one side of each rotor electromagnet, is a second electromagnet spaced on a 13.5 degree centreline from the major rotor electromagnet. Electromagnets in both the rotor and stator assemblies are identical, the individual electromagnets of each being aligned axially and the coils of each being wired so that each rotor electromagnetic pole will have the same magnetic polarity as the electromagnet in the stator with which it is aligned and which it is confronting at the time of discharge of the capacitor.

Charging of the discharge capacitor or capacitors is accomplished by an electrical switching circuit wherein electrical energy from a battery or other source of d-c potential is derived through rectification by diodes.

The capacitor charging circuit comprises a pair of high frequency switchers which feed respective automotive-type ignition coils employed as step-up transformers. The "secondary" of each of the ignition coils provides a high voltage square wave to a half-wave rectifier to generate a high voltage output pulse of d-c energy with each switching alternation of the high frequency switcher. Only one polarity is used so that a unidirectional pulse is applied to the capacitor bank being charged.

Successive unidirectional pulses are accumulated on the capacitor or capacitor bank until discharged. Discharge of the bank of capacitors occurs across a spark gap by arc-over. The gap spacing determines the voltage at which discharge or arc-over occurs. An array of gaps is created by fixed elements in the engine housing and moving elements positioned on the rotor shaft. At the instant when the moving gap elements are positioned opposite fixed elements during the rotor rotation, a discharge occurs through the coils of the aligned rotor and stator electromagnets to produce the repulsion action between the stator and rotor electromagnet cores.

A plurality of fixed gap elements are arrayed in a motor housing to correspond to the locations of the stator electromagnets in the housing. The rotor gap elements correspond to the positions of the rotor electromagnets on the rotor so that at the instant of correct alignment of the gaps, the capacitors are discharged to produce the necessary current through the stator and rotor coils to cause the electromagnets to repel one another.

The charging circuits are arranged in pairs, and are such that the discharge occurs through both rotor and stator windings of the electromagnets, which are opposite one another when the spark gap elements are aligned and arc-over.

The speed of the rotor can be changed by means of a clutch mechanism associated with the rotor. The clutch shifts the position of the rotor gap elements so that the discharge will energise the stator coils in a manner to advance or retard the time of discharge with respect to the normal rotor/stator alignment positions. The discharge through the rotor and stator then occurs when the rotor has passed the stator by 6.66 degrees for speed advance.

By causing the discharge to occur when the rotor position is approaching the stator, the repulsion pulse occurs 6.66 degrees before the alignment position of the rotor and stator electromagnets, thus reducing the engine speed.

The clutch mechanism for aligning capacitor discharge gaps for discharge is described as a control head. It may be likened to a firing control mechanism in an internal combustion engine in that it “fires” the electromagnets and provides a return of any discharge overshoot potential back to the battery or other energy source.

The action of the control head is extremely fast. From the foregoing description, it can be anticipated that an increase in speed or a decrease in speed of rotation can occur within the period in which the rotor electromagnet moves between any pair of adjacent electromagnets in the stator assembly. These are 40 degrees apart so speed changes can be effected in a maximum of one-ninth of a revolution.

The rotor speed-changing action of the control head and its structure are believed to be further novel features of the invention, in that they maintain normal 120 degree firing positions during uniform speed of rotation conditions, but shift to 6.66 degree longer or shorter intervals for speed change by the novel shift mechanism in the rotor clutch assembly.

Accordingly, the preferred embodiment of this invention is an electric rotary engine wherein motor torque is developed by discharge of high potential from a bank of capacitors, through stator and rotor electromagnet coils when the electromagnets are in alignment. The capacitors are charged from batteries by a switching mechanism, and are discharged across spark gaps set to achieve the discharge of the capacitor charge voltage through the electromagnet coils when the gaps and predetermined rotor and stator electromagnet pairs are in alignment.

Exemplary embodiments of the invention are herein illustrated and described. These exemplary illustrations and description should not be construed as limiting the invention to the embodiments shown, because those skilled in the arts appertaining to the invention may conceive of other embodiments in the light of the description within the ambit of the appended claims.

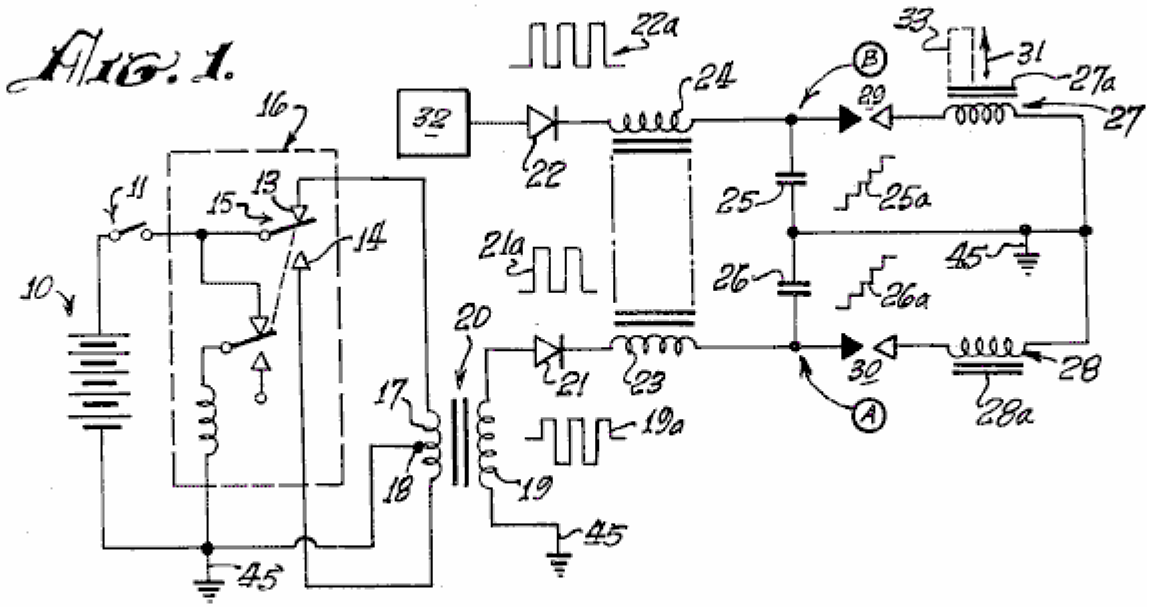
DESCRIPTION OF THE PREFERRED EMBODIMENT

As mentioned earlier, the basic principle of operation of the engine of the invention, is the discharge of a capacitor across a spark gap and through an inductor. When a pair of inductors is used, and the respective magnetic cores thereof are arranged opposite one another and arranged in opposing magnetic polarity, the discharge through them causes the cores to repel each other with considerable force.



Referring to the electrical schematic diagram of **Fig.1**, a battery **10** energises a pulse-producing vibrator mechanism **16**, which may be of the magnetic type, incorporating an armature **15** moving between contacts **13** and **14**, or of the transistor type (not shown) with which a high frequency bipolar pulsed output is produced in primary **17** of transformer **20**. The pulse amplitude is stepped up in secondary **19** of transformer **20**. Wave form **19a** represents the bi-directional or bi-polar pulsed output. A diode rectifier **21** produces a unidirectional pulse train, as indicated at **21a**, to charge capacitor **26**. Successive unidirectional pulses of wave **21a** charge capacitor **26** to high level, as indicated at **26a**, until the voltage at point **A** rises high enough to cause a spark across the spark gap **30**. Capacitor **26** discharges via the spark gap, through the electromagnet coil **28**. A current pulse is produced which magnetises core **28a**. Simultaneously, another substantially identical charging system **32** produces a discharge through inductor **27** across spark gap **29**, to magnetise core **27a**. Cores **27a** and **28a** are wound with coils **27** and **28** respectively, so that their magnetic polarities are the same. As the cores **27a** and **28a** confront one another, they tend to fly apart when the discharge occurs through coils **27** and **28** because of repulsion of identical magnetic poles, as indicated by arrow **31.** If core **28a** is fixed or stationary, and core **27a** is moveable, then core **27a** may have tools **33** attached to it to perform work when the capacitor discharges.

Referring to **Fig.1** and **Fig.2**, a d-c electrical source or battery **10**, energises pulsators **36** (including at least two vibrators **16** as previously described) when switch 11 between the battery **10** and pulsator **36** is closed, to apply relatively high frequency pulses to the primaries of transformers **20**. The secondaries of transformers **20** are step-up windings which apply bipolar pulses, such as pulses **19a** (Fig.1) to the diodes in converter **38**. The rectified unidirectional pulsating output of each of the diodes in converter **38** is passed through delay coils **23** and **24**, thus forming a harness **37**, wound about the case of the engine, as herein after described, which is believed to provide a static floating flux field. The outputs from delay lines **37**, drive respective capacitors in banks **39**, to charge the capacitors therein, to a relatively high charge potential. A programmer and rotor and stator magnet control array **40**, **41**, **42**, is formed by spark gaps positioned, as hereinafter described, so that at predetermined positions of the rotor during rotation of the engine, as hereinafter described, selected capacitors of the capacitor banks **39** will discharge across the spark gaps through the rotor and stator electromagnets **43** and **44**. The converters **38**, programmer **40**, and controls **41** and **42**, form a series circuit path across the secondaries of transformers **20** to the ground, or point of reference potential, **45**. The capacitor banks **39** are discharged across the spark gaps of programmer **40** (the rotor and stator magnet controls **41** and **42**). The discharge occurs through the coils of stator and rotor electromagnets **43** and **44** to ground **45**. Stator and rotor electromagnets are similar to those shown at **27**, **27a**, **28** and **28a** in **Fig.1**.

The discharge through the coils of stator and rotor electromagnets **43** and **44** is accompanied by a discharge overshoot or return pulse, which is applied to a secondary battery **10a** to store this excess energy. The overshoot pulse returns to battery **10a** because, after discharge, the only path open to it is that to the battery **10a**, since the gaps in **40**, **41** and **42** have broken down, because the capacitors in banks **39** are discharged and have not yet recovered the high voltage charge from the high frequency pulsers **36** and the converter rectifier units **38**.

In the event of a misfire in the programmer control circuits **40**, **41** and **42**, the capacitors are discharged through a rotor safety discharge circuit **46** and returned to batteries **10-10a**, adding to their capacity. The circuit **46** is connected between the capacitor banks **39** and batteries **10**, **10a**.

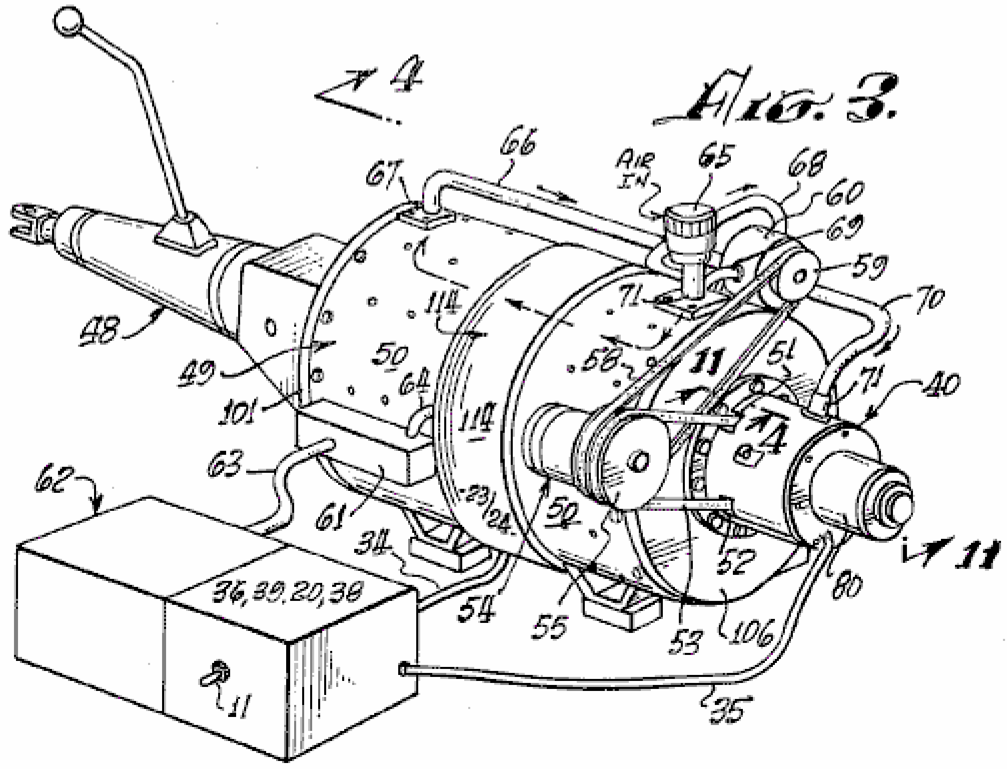


Fig. 3.

Referring to **Fig.3**, a motor or engine **49** according to the present invention is shown connected with an automotive transmission **48**. The transmission **48**, represents one of many forms of loads to which the engine may be applied. A motor housing **50**, encases the operating mechanism hereinafter described. The programmer 40 is axially mounted at one end of the housing. Through apertures **51** and **52**, a belt **53** couples to a pulley **57** (not shown in this view) and to an alternator **54** attached to housing **50**. A pulley **55** on the alternator, has two grooves, one for belt **53** to the drive pulley **58** on the shaft (not shown) of the engine **49**, and the other for a belt **58** coupled to a pulley **59** on a pump **60** attached to housing **50**, A terminal box **61** on the housing, interconnects between the battery assembly **62** and motor **49** via cables **63** and **64**.

An intake **65** for air, is coupled to pump **60** via piping **68** and **69** and from pump **60** via tubing or piping **66** and **70** to the interior of housing **50** via coupling flanges **67** and **71**. The air flow tends to cool the engine and the air may preferably be maintained at a constant temperature and humidity so that a constant spark gap discharge condition is maintained. A clutch mechanism **80** is provided on programmer **40**.

Referring to **Fig.4**, **Fig.5** and **Fig.9**, rotor **81** has spider assemblies **83** and **84** with three electromagnet coil assembly sets mounted thereon, two of which are shown in **Fig.4**, on **85**, at **85a** and **85b** and on **86** at **86a** and **86b**. One of the third electromagnet coil assemblies, designated **87a**, is shown in **Fig.5**, viewed from the shaft end. As more clearly shown in the perspective view of **Fig.8**, a third spider assembly **88** provides added rigidity and a central support for the rotor mechanism on shaft **81**.

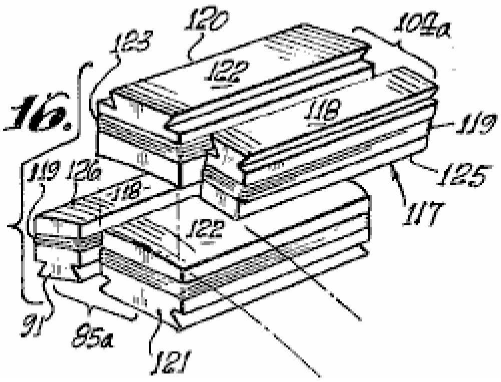
The electromagnet sets **85a**, **85b**, **86a**, **86b**, **87a** and **87b**, disposed on rotor **81** and spiders **83**, **84** and **88**, each comprise pairs of front units **85a**, **86a** and **87a** and pairs of rear units **85b**, **86b** and **87b**. Each pair consists of a major electromagnet and a minor electromagnet, as hereinafter described, which are imbedded in an insulating material **90**, which insulates the electromagnet coil assemblies from one another and secures the electromagnets rigidly in place on the spider/rotor cage **81**, **83**, **84** and **88**.

The interior wall **98**, of housing **50**, is coated with an electrically insulating material **99** in which are imbedded electromagnet coils, as hereinafter described, and the interiors of end plates **100** and **101** of the housing **50**. On the insulating surface 98 of housing **50** is mounted a series of stator electromagnet pairs **104a**, identical with electromagnet pairs **85a**, **86a**, **87a**, etc. Electromagnet pairs such as **104a** or **105a** are disposed every **40** degrees about the interior of housing **50** to form a stator which co-operates with the rotor **81-88**. An air gap **110** of very close tolerance is defined between the rotor and stator electromagnets and air from pump **65** flows through this gap.

As shown in **Fig.8**, the electromagnet assemblies, such as **85** through **87**, of the rotor and magnet assemblies, such as **104a** in the stator, are so embedded in their respective insulating plastic carriers (rotor and stator) that they are smoothly rounded in a concave contour on the rotor to permit smooth and continuous rotation of rotor **81** in stator housing **50**. The air gap **110** is uniform at all positions of any rotor element within the stator assembly, as is clearly shown in **Fig.16**.

Fig. 16.



The rotor **81** and spiders **83**, **84** and **88** are rigidly mounted on shaft **111** journaled in bearing assemblies **112** and **113** which are of conventional type, for easy rotation of the rotor shaft **111** within housing **50**.

Around the central outer surface of housing **50**, are wound a number of turns of wire **23** and **24** to provide a static flux coil **114** which is a delay line, as previously described. **Figs. 5, 6, 7** and **9** are cross-sectional views of the rotor assembly **81-88**, arranged to show the positioning and alignment of the rotor and stator electromagnet coil assemblies at successive stages of the rotation of the rotor **81-88** through a portion of a cycle of operation thereof. For example, in **Fig.5** the rotor assembly **81-88** is shown so positioned that a minor rotor electromagnet assembly **91** is aligned with a minor stator electromagnet assembly **117**.

As shown in further detail in **Fig.16**, minor electromagnet assembly **117** consists of an iron core **118**, grooved so that a coil of wire **119** may be wound around it. Core **118** is the same in stator electromagnet **117** as it is in rotor electromagnet **91**.

As a position 13.33 degrees to the right of rotor electromagnet **91**, as viewed in **Fig.5** and **Fig.16**, there is a second or major rotor electromagnet **121** which has a winding **123** about its core **122**. The electromagnets **91** and **121** are the pair **85a** of **Fig.4** and **Fig.8**.

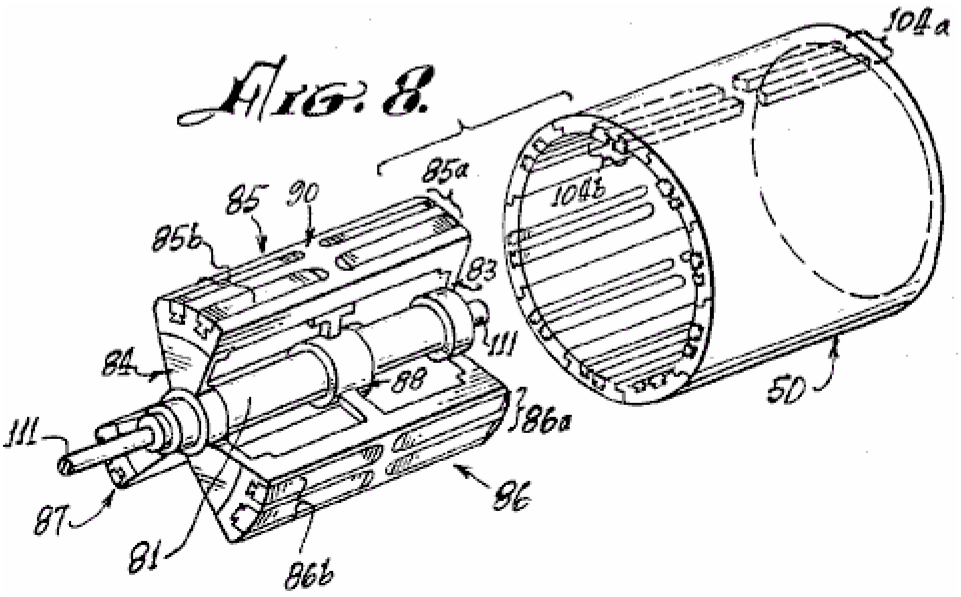


Fig. 8.

At a position 13.33 degrees to the left of stator electromagnet **117**, as viewed in **Fig.5**, there is a second or major stator electromagnet **120** whose core **122** is of the same configuration as core **122** of rotor electromagnet **121**. A winding **123** about core **122** of electromagnet **120** is of the same character as winding **123** on electromagnet **121**.

Electromagnet assembly pair **85a** on the rotor is identical in configuration to that of the electromagnet stator assembly pair **104a** except for the position reversal of the elements **117-120** and **91-121** of the respective pairs.

There are none pairs of electromagnets **120-117** (**104a**) located at 40 degree intervals about the interior of housing **50**. The centreline of core **122** of electromagnet **120** is positioned 13.33 degrees to the left of the centreline of the core **118** of electromagnet **117**. Three pairs of electromagnets **85a**, **86a** and **87a** are provided on rotor assembly **81-88** as shown in **Fig.5**.

Other combinations are possible, but the number of electromagnets in the rotor should always be in integral fraction of the number of electromagnets in the stator. As shown in **Fig.8**, for the rotor assembly **85a** and **85b**, there are three of each of the front and back pairs of electromagnetic assemblies. Similarly, as shown in **Fig.4** and **Fig.8**, there are nine front and back pairs of electromagnets in the stator such as **104a** and **104b**.

In order to best understand the operation of the rotor **81-88** rotating within the stator housing **50** of an engine according to this invention, the positions of rotor electromagnets **91** and stator electromagnets **117** are initially exactly in line at the 13.33 degree peripheral starting position marked on the vertical centreline of **Fig.5**. The winding direction of the coils of these magnets is such that a d-c current through the coils **119** will produce a particular identical magnet polarity on each of the juxtaposed surfaces **125** of magnet **117** and **126** of magnet **91** (**Fig.5**). **Fig.16** and **Fig.6** illustrate the next step in the motion wherein the two major electromagnets, **120** in the stator and **121** in the rotor, are in alignment.

When the d-c discharges from the appropriate capacitors in banks **39** occur simultaneously across spark gaps through the coils **119** of electromagnets **117** and **91**, at the instant of their alignment, their cores **118**, will repel one another to cause rotor assembly **81-88** to rotate clockwise in the direction indicated by arrow **127**. The system does not move in the reverse direction because it has been started in the clockwise direction by the alternator motor **54** shown in **Fig.3**, or by some other starter means. If started counterclockwise, the motor will continue to rotate counterclockwise.

As noted earlier, the discharge of any capacitor occurs over a very short interval via its associated spark gap and the resulting magnetic repulsion action imparts motion to the rotor. The discharge event occurs when electromagnets **117** and **91** are in alignment. As shown in **Fig.5**, rotor electromagnet **91a** is aligned with stator electromagnet **117c**, and rotor electromagnet **91b** is aligned with stator electromagnet **117e** at the same time that similar electromagnets **117** and **91** are aligned. A discharge occurs through all six of these electromagnets simultaneously (that is, **117**, **91**, **117c**, **91a**, **117e** and **91b**). A capacitor and a spark gap are required for each coil of each electromagnet. Where, as in the assembly shown in **Fig.8**, front and back pairs are used, both the axial in-line front and back coils are energised simultaneously by the discharge from a single capacitor or from a bank of paralleled capacitors such as **25** and **26** (**Fig.1**). Although **Fig.4** and **Fig.8** indicate the use of front and back electromagnets, it should be evident that only a single electromagnet in any stator position and a corresponding single electromagnet in the rotor position, may be utilised to accomplish the repulsion action of the rotor with respect to the stator. As stated, each electromagnet requires a discharge from a single capacitor or capacitor bank across a spark gap for it to be energised, and the magnetic polarity of the juxtaposed magnetic core faces must be the same, in order to effect the repulsive action required to produce the rotary motion.

Referring to **Fig.5** and **Fig.6**, the repulsion action causes the rotor to move 13.33 degrees clockwise, while electromagnets **91**, **91a** and **91b** move away from electromagnets **117**, **117c** and **117e** to bring electromagnets **121**, **121a** and **121b** into respective alignment with electromagnets **120a**, **120d** and **120f**. At this time, a capacitor discharge across a spark-gap into their coils **123** occurs, thus moving the rotor. Another 13.33 degrees ahead, as shown in **Fig.7**, major electromagnets 121, 121a and 121b come into alignment with minor electromagnets **117a**, **117d** and **117f**, at which time a discharge occurs to repeat the repulsion action, this action continuing as long as d-c power is applied to the system to charge the capacitor banks.

Fig.18 further illustrates the sequencing of the capacitor discharges across appropriate spark gap terminal pairs. Nine single stator coils and three single rotor coils are shown with their respective interconnections with the spark gaps and capacitors with which they are associated for discharge. When the appropriate spark gap terminals are aligned, at the points in the positioning of the rotor assembly for most effective repulsion action of juxtaposed electromagnet cores, the discharge of the appropriate charged capacitors across the associated spark gap occurs through the respective coils. The capacitors are discharged is sets of three, through sets of three coils at each discharge position, as the rotor moves through the rotor positions. In **Fig.18**, the rotor electromagnets are positioned linearly, rather than on a circular base, to show the electrical action of an electric engine according to the invention. These motor electromagnets **201**, **202** and **203** are aligned with stator electromagnets **213**, **214** and **215** at 0 degrees, 120 degrees and 240 degrees respectively. The stator electromagnets are correspondingly shown in a linear schematic as if rolled out of the stator assembly and laid side by side. For clarity of description, the capacitors associated with the rotor operation **207**, **208**, **209** and **246**, **247**, **248**, **249**, **282** and **283**, are arranged in vertical alignment with the respective positions of the rotor coils **201**, **202** and **203** as they move from left to right, this corresponding to clockwise rotation of the rotor. The stator coils **213, 214, 215, 260, 261, 262, 263, 264, 265, 266,** etc. and capacitor combinations are arranged side by side, again to facilitate description.

An insulative disc **236** (shown in **Fig.17** as a disc but opened out linearly in **Fig.18**) has mounted thereon, three gap terminal blocks **222**, **225** and **228**. Each block is rectangularly U-shaped, and each interconnects two terminals with the base of the U. Block **222** has terminals **222a** and **222b**. Block **225** has terminals **225a** and **225b**. Block **228** has terminals **228c** and **228d**. When insulative disc **230** is part of the rotor as indicated by mechanical linkage **290**, it can be seen that terminal U **222** creates a pair of gaps with gap terminals **223** and **224** respectively. Thus, when the voltage on capacitor **216** from charging unit **219**, is of a value which will arc over the air spaces between **222a** and **223**, and between **222b** and **224**, the capacitor **216** will discharge through the coil of electromagnet **213** to ground. Similarly, gap terminal U 225 forms a dual spark gap with gap terminals **226** and **227** to result in arc-over when the voltage on capacitor **217**, charged by charging circuit **220**, discharges into the coil of electromagnet **214**. Also, U-gap terminal **228** with terminals **228c** and **228d**, creates a spark gap with terminals **229** and **230** to discharge capacitor **218**, charged by charging circuit **221**, into coil **215**. At the same time, rotor coils, **201**, **202** and **203** across gaps **201a - 204**, **202b - 205** and **203c - 206** each receives a discharge from respective capacitors **207**, **208** and **209**.

When the electromagnet coils **213**, **214** and **215** and **201**, **202** and **203** are energised, the repulsion action causes the rotor assembly to move to position 2 where a new simultaneous group of discharges occurs into rotor coils **201**, **202** and **203** from capacitors **246**, **248** and **282** across gaps **201a - 240**, **202b - 242** and **203c - 244**. Simultaneously, because gap-U-elements **222**, **225** and **228** have also moved to position 2 with the rotor assembly, capacitor **261** is discharged through electromagnet coil **260**, capacitor **265** is discharged through electromagnet coil **264**, and capacitor **269** is discharged through electromagnet coil **268** in alignment with position 2 of the rotor electromagnet coils, thus to cause the rotor electromagnets to move to position 3 where the discharge pattern is repeated now with capacitors **247**, **249** and **283** discharging through the rotor electromagnet coils **201**, **202** and **203**, and the capacitors **263**, **267** and **281** discharging respectively through stator electromagnet coils **262**, **266** and **280**.

After each discharge, the charging circuits **219 - 221** and **272 - 277** for the stator capacitors, and **210 - 212** and **284 - 289** for the rotor capacitors, are operated continuously from a battery source as described earlier with reference to **Fig.1**, to constantly recharge the capacitors to which each is connected. Those versed in the art will appreciate that, as each capacitor discharges across an associated spark gap, the resulting drop in potential across the gap renders the gap an open circuit until such time as the capacitor can recharge to the arc-over level for the gap. This recharge occurs before a rotor element arrives at the next position in the rotation.

The mechanical schematic diagram of **Fig.17**, further clarifies the operation of the spark-gap discharge programming system. A forward disc **236** of an electrically insulative material, has thereon the set of U-shaped gap terminal connectors previously described. These are positioned at 0 degrees, 120 degrees and 240 degrees respectively. In **Fig.17**, schematic representations of the position of the coil and capacitor arrangements at the start of a cycle are shown to correspond to the above description with reference to **Fig.18**. Accordingly, the coil and capacitor combinations **213/216, 214/217** and **215/218** are shown connected with their gap terminals, respectively, **223/224, 226/227** and **229/230**. On the rotor coil and capacitor connection, three separate discs **291, 292** and **293** are shown, each with a single gap terminal. The discs **291 - 293** are rotated so as to position their respective gap terminals 201a, 201b and 201c, at 120 degree increments, with the 0 degrees position corresponding to the 0 degrees position of U-gap terminal **222** on disc **230**.

Representative gap terminals are shown about the peripheries of discs **230, 291 - 293** to indicate clearly how, as the discs turn in unison, the gap alignments correspond so that three rotor coils always line up with three stator coils at 120 degree intervals about the rotary path, producing an alignment every 40 degrees, there being nine stator coils. Thus, there are three simultaneous discharges into stator coils and three into rotor coils at each 40 degree position. Nine positions displaced 40 degrees apart provide a total of 27 discharge points for capacitors into the rotor coils and 27 discharge points for capacitors into the stator coils in one revolution of the rotor.

It will be understood that, as illustrated in **Fig.17** and **Fig.18**, nine individual electromagnet coils are shown in the stator and three in the rotor, in order to show in its simplest form, how the three rotor electromagnets are stepped forward from alignment with three of the stator electromagnets, when the appropriate spark gaps are in alignment, to effect the discharge of capacitors through juxtaposed pairs of rotor/stator electromagnets. The repulsion moves the rotor electromagnet from the stator electromagnet to the next alignment position 40 degrees further on. In the interval, until another rotor electromagnet, 120 degrees removed, is aligned with the stator electromagnet which had just been pulsed, the associated capacitor is recharged. Thus, the rotor moves from one position to the next, with capacitor discharges occurring each 40 degrees of rotation, a total of nine per revolution. It should be obvious that, with other rotor/stator combinations, the number of electromagnet coincidences and spark-gap discharges will vary. For example, with the coil pairs shown in **Figs 4 through 8**, a total of 27 discharges will occur. Although there are 18 stator electromagnets and 3 rotor electromagnets, the discharge pattern is determined by the specific spark gap arrangement.

The rotor/stator configuration of **Fig.5** and **Fig.8**, involving the major and minor pairs of electromagnets, such as **85a** and **104a** (the terms “minor” and “major” referring to the difference in size of the elements), include nine pairs of electromagnets in the stator, such as **104a**, with three electromagnet pairs of the rotor, such as **85a**. Because of the 13.33 degree separation between the major and minor electromagnets in the rotor pair **85a**, with the same separation of minor and major electromagnets of the stator pair **104a**, the sequence of rotation and discharge described above, with respect to the illustrative example of **Fig.5**, involves the following:

1. A minor element **117** of stator pair **104a** is aligned with the minor element **91** of rotor pair **85a**. On the discharge, this moves the rotor ahead 13.33 degrees.
2. the major rotor element **122** of the pair **85a**, now is aligned with the major stator element **120b** of the next stator electromagnet pair, in the stator array as shown in **Fig.6**. On the discharge, the rotor moves ahead 13.33 degrees.
3. This brings the minor rotor electromagnet **91** into alignment with the major stator electromagnet **120b** of pair **104d**, and the major electromagnet **122** (just discharged) of pair **85a** into alignment with minor electromagnet **117b** of pair **104d**, and the rotor spark gap elements into alignment with a different position of gap elements connected with capacitors not discharged in the previous position of the rotor. It should be remembered at this point that it is the positioning of a rotatable spark gap array, similar to that illustrated in **Fig.17** and **Fig.18**, which controls the time of discharge of capacitors connected to these gap terminals. Therefore, any electromagnet can be energised twice, successively, from separate capacitors as the rotor brings appropriate gap terminals into alignment with the coil terminals of a particular electromagnet.

Thus, although major electromagnet **120b** of pair **104d** has just been energised as described above, it can now be energised again along with minor rotor electromagnet **91** in step 3, because the rotor moved to a new set of terminals of the spark gap arrays connected to capacitors which have not yet been discharged. These capacitors now discharge through rotor electromagnet **91** and stator electromagnet **120b**, causing the rotor to move ahead another 13.33 degrees, thus again aligning two minor electromagnets again, these being **117b** of stator pair **104d** and **91** of rotor pair **85a**. The rotor has now moved 40 degrees since step 1 above. The sequence is now repeated indefinitely. It is to be noted that at each 13.33 degree step, the discharges drive the rotor another 13.33 degrees. There are 27 steps per revolution with nine stator coil pairs. The discharge sequence is not uniform, as is shown in Table 1. In the stator, three major electromagnets 120 degrees apart are energised twice in sequence, followed by a hiatus of one step while three minor electromagnets of the stator, 120 degrees apart, are energised during the hiatus. In the rotor the major electromagnets are energised during a hiatus step following two minor electromagnet energisation steps. A total of 27 energisations are this accomplished in the nine pairs of coils of the stator.

In Table 1, the leftmost column shows the location of each rotor arm **85, 86** and **87** at an arbitrarily selected step No. 1 position. For example, in step 1, rotor arm **85** has a minor stator and minor rotor electromagnet in alignment for capacitors to discharge through them simultaneously at the 13.33 degree position.

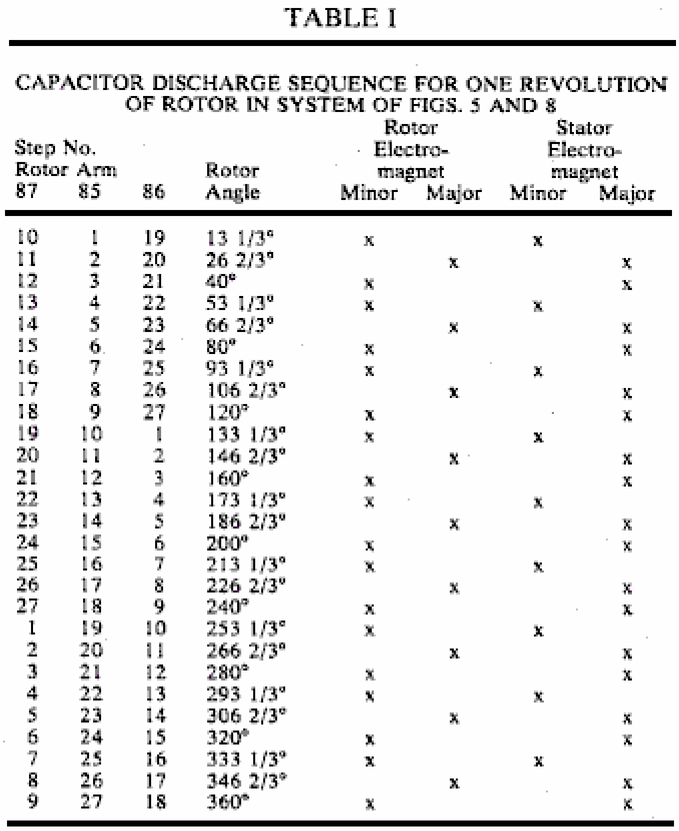

TABLE I

CAPACITOR DISCHARGE SEQUENCE FOR ONE REVOLUTION OF ROTOR IN SYSTEM OF FIGS. 5 AND 8

Step No. Rotor Arm 87	85	86	Rotor Angle	Rotor Electro-magnet Minor	Major	Stator Electro-magnet Minor	Major
10	1	19	13 1/3°	x		x	
11	2	20	26 2/3°		x		x
12	3	21	40°	x			x
13	4	22	53 1/3°	x		x	
14	5	23	66 2/3°		x		x
15	6	24	80°	x			x
16	7	25	93 1/3°	x		x	
17	8	26	106 2/3°		x		x
18	9	27	120°	x			x
19	10	1	133 1/3°	x		x	
20	11	2	146 2/3°		x		x
21	12	3	160°	x			x
22	13	4	173 1/3°	x		x	
23	14	5	186 2/3°		x		x
24	15	6	200°	x			x
25	16	7	213 1/3°	x		x	
26	17	8	226 2/3°		x		x
27	18	9	240°	x			x
1	19	10	253 1/3°	x		x	
2	20	11	266 2/3°		x		x
3	21	12	280°	x			x
4	22	13	293 1/3°	x		x	
5	23	14	306 2/3°		x		x
6	24	15	320°	x			x
7	25	16	333 1/3°	x		x	
8	26	17	346 2/3°		x		x
9	27	18	360°	x			x

Similarly, in step 1, rotor arm **86** is at the 133.33 degree position which has two minor electromagnets in alignment, ready for discharge. Simultaneously, rotor arm 87 is at the 253.33 degree position with two minor electromagnets aligned for capacitor discharge. The other steps of the sequence are apparent from Table 1, for each position of the three rotor arms at any step and the juxtapositions of respective stator and rotor electromagnet elements at that position.

In the simplified motor arrangement shown in schematic form in **Fig.18**, with single electromagnet configuration, the alignment is uniform and the discharge sequences follow sequentially.

As mentioned before, a change in speed is effected by displacing the stator spark gap terminals on the rotor (shown at **236** in **Fig.17** and **Fig.18**) either counterclockwise or clockwise 6.66 degrees so that the discharge position of the stator electromagnets is displaced. Referring to **Figs. 11 to 15**, the simultaneous discharge of selected capacitors into the displaced electromagnets results in a deceleration if the rotor electromagnet is approaching the stator electromagnet at the time of discharge, or an acceleration if the rotor electromagnet is leaving the stator electromagnet at the time of the discharge pulse. In each event, there is a repulsive reaction between the stator and rotor electromagnets which effects this change in speed.

Referring to **Fig.11**, clutch mechanism **304** about shaft **111** is operated electromagnetically in conventional manner, to displace the spark-gap mechanism **236** which is operated normally in appropriate matching alignment with the rotor spark-gap discs **291, 292** and **293**. Clutch **304** has a fixed drive element **311**, containing an electromagnetic drive coil (not shown) and a motor element **310** which, when the electromagnetic drive coil is energised, can be operated by a direct current. The operation of motor element 310, brings into operation, spark gap elements **224r, 223r** or **223f, 224f** of the system shown in **Figs. 4, 5 and 8,** as illustrated in **Fig.19**.

The fixed stator coil spark gap terminal pairs **223, 224** and **266, 267** are arrayed about a cylindrical frame **322** which is fabricated in insulative material. In the illustrative example of **Fig.17** and **Fig.18**, there are nine such spark gap terminal pairs positioned around the periphery of the cylinder frame **324**. In the engine of **Figs. 4 to 8**, a total of 27 such spark gap pairs are involved. In addition, although not shown in the drawing, there are also pairs of terminals, such as **223r or 223f**, **224r or 224f** and **226r or 226f**, **267r or 267f**, displaced 6.66 degrees on either side of the pairs **223, 224** or **266, 267** and all other pairs in the spark gap array, the letters “r” and “f” denoting “retard” or “faster”. The latter displaced pairs are used in controlling the speed of the engine rotor. The displaced pairs not shown are involved in the operation of the clutch **304**, the speed-changing control element.

Clutch **304** is associated with shaft **111** in that the movable element **310** draws clutch disc element **316** on shaft **111**, away from clutch disc element **322** when energised by a voltage of appropriate polarity applied to its motor electromagnet **311**. Such clutch drives are well known in the art.

The clutch mechanism **304** of **Fig.11** and **Fig.19**, when not energised, is in the configuration shown in **Fig.11**. The energised configuration of clutch **304** is not specifically illustrated. Upon energisation, spark-gap element **222** on disc **236** is displaced rightward, as viewed in **Fig.11**, by broken lines **236X**, into alignment with the positions of fixed spark-gap terminals **223f, 224f** and **267r, 266r**. When the disc is in position **236X**, the flattened edge **332** of pin **330** in disc **325** rides on surface **350** of disc **322**. Normally, the flattened edges **351** of pins **330** are engaged against the flat edge **352** in recess **331** of disc **322**. The displacement of disc **322** on shaft **111** is effected by the action of clutch **304** against spring **314** (Fig.11). An electric switch (not shown) of clutch mechanism **304** energises it from a d-c power source, and has two positions, one for deceleration and one for acceleration. In either position, clutch **304** is engaged to pull clutch disc **322** from clutch disc **325**, momentarily. For the decelerate or the accelerate position, the displaced alignment of spark gap elements **222** is with the **224f, 223f** and the **224r, 223r** spark-gap terminal elements. However, only the **224f, 223f** spark-gap elements are switched into operation with appropriate capacitors for the accelerate position, while in the decelerate position, only the **223r and 224r** spark-gap elements are switched into the circuit with their associated capacitors.

Of course, when insulative disc **236** is displaced by clutch **304**, its gap terminals **222, 225** and **228** (**Fig.14** and **Fig.18**) are all displaced into the alignment position of **236X** so as to engage the “r” and “f” lines of fixed spark gap elements. Although the accelerate and decelerate positions of disc **236** are the same, it is the switching into operation of the **223, 224** or **266, 267** exemplary “r” or “f” pairs of terminals which determines whether the rotor will speed up or slow down.

The momentary displacement of clutch disc **322** from clutch disc **325** results in rotation of disc **325** about disc **322** through an angle of 120 degrees. The detent ball and spring mechanism **320, 321** in disc **325**, positions itself between one detent dimple **328** and a succeeding one **328** at a position 120 degrees away on disc **325**.

As stated, flat **332** of pin **330** rides on surface **350** of disc **322**, and pin **330** leaves the pin-holding groove **331/352** along ramp **333** in disc **322** during the momentary lifting of disc **322** by clutch **304**. Pin **330** falls back into the next groove **331** at a point 120 degrees further on about disc **322**. Pin **330** falls into place in groove **331** on ramp **334**. Pins **330** are rotatable in their sockets **353**, so that for either clockwise or counterclockwise rotation, the flat **351** will engage the flat **352** by the particular ramp it encounters.

The deceleration or acceleration due to the action of clutch **304** thus occurs within a 120 degree interval of rotation of disc **325**. During this interval, disc **322** may only move a fraction of this arc.

There has been described earlier, an electromotive engine system wherein at least one electromagnet is in a fixed position and a second electromagnet of similar configuration is juxtaposed with it in a magnetic polarity relationship such that, when the cores of the electromagnets are energised, the juxtaposed core faces repel each other. One core being fixed, and the second core being free to move, any attachments to the second electromagnet core will move with it. Hence, if a plurality of fixed cores are positioned about a circular confining housing, and, within the housing, cores on a shaft are free to move, the shaft is urged rotationally each time the juxtaposed fixed and rotatable cores are in alignment and energised. Both the fixed and the movable cores are connected to spark gap terminal elements and the associated other terminal elements of the spark gaps are connected to capacitors which are charged to high voltage from pulsed unipolar signal generators. These capacitors are discharged through the electromagnets across the spark gaps. By switching selected groups of capacitors into selected pairs of spark gap elements for discharge through the electromagnets, the rotor of the circular array systems is accelerated and decelerated.

By confining a fixed electromagnet array in a linear configuration, with a linearly movable electromagnet to which a working tool is attached, exciting the juxtaposed pairs of electromagnets by capacitor discharge, results in the generation of linear force for such tools as punch presses, or for discharging projectiles with considerable energy.

CLAIMS:

1. An electric engine comprising:

A housing;

An array of electromagnets uniformly spaced in said housing to form a stator;

A rotor cage on a shaft journaled in and rotatable within said stator, said rotor cage having thereon a spaced array of electromagnets similar to said stator electromagnets and in number, comprising an integral fraction of the number of electromagnets in said stator array;

Each of the electromagnets of said stator and of said rotor, having a core which can be magnetised and of a particular configuration and each being wound with a coil such that a pulses of unidirectional electric current through said coil, magnetises the respective core thereof to a particular magnetic polarity, and the faces of rotor cores juxtaposing selected stator cores are magnetised to the same polarity, the juxtaposed cores thereby tending to repel one another, one lead of each of the stator and rotor coils being connected to a common terminal, the other lead of each of said coils being connected to a gap terminal, the gap terminals of said rotor coils being on the rotor and equal in number to the number of coils thereon and matching the positions of said rotor electromagnets thereon, the gap terminals of said stator being equal in number to the number of coils on the stator and disposed uniformly about said stator to match the positions of said stator electromagnets within said housing;

A first array of capacitors, each having a terminal in common with the common coil terminal of said stator electromagnets, and each capacitor having its other terminal connected to a gap terminal arrayed adjacent the gap terminal of an electromagnet associated therewith;

A second array of capacitors, each having a terminal in common with said common terminal of said rotor electromagnet coils but equal in number to the number of capacitors in said stator array, the other terminals of said capacitors in said second array being connected to gap terminals arrayed about said housing so as to be in axial alignment with said stator gap terminal positions and being alignable with said rotor gap terminals as said rotor is rotated in said housing and respective gap terminals of said rotor coils pass each second array capacitor gap terminals at a predetermined gap distance;

Gap coupling terminals on said rotor equal in number to the number of rotor electromagnet coils and positioned to match the rotor electromagnet positions on said rotor, the gap coupling terminals being rotatable with said rotor so as to pass said adjacent stator coil and associated stator capacitor gap terminal at a predetermined distance therefrom;

A plurality of capacitor charging circuits connected respectively across each of said capacitors in both said first and said second arrays of capacitors for charging each of said capacitors to a predetermined high d-c potential;

A first source of unidirectional electric potential connected to each of said capacitor charging circuits for energising said charging circuits; and

A second unidirectional electric potential source connected to said electromagnets of said rotor and said stator of such polarity as to receive a charge from the inverse inductive discharge of the electromagnet coils as their fields collapse following the discharge of each capacitor through a rotor or stator electromagnet coil,

Whereby, whenever a rotor electromagnet is aligned opposite a stator electromagnet, the rotor coil gap terminal of that electromagnet is opposite an associated second capacitor array gap terminal, and a gap coupling terminal of said rotor is aligned opposite the stator electromagnet coil gap terminal and associated first capacitor gap terminal, the capacitors discharge the charge thereon across the gaps through their associated electromagnet coils to magnetise their respective juxtaposed electromagnet cores to cause them to repel one another, thus aligning a succeeding pair of rotor and stator electromagnets for capacitor discharge across their respective gaps, to cause them to repel one another, alignments rotor rotation within the housing continuously bringing successive rotor-stator electromagnets into alignment for discharge of the capacitors through them to produce continuous rotary motion of the rotor on said rotor shaft, so long as energy is applied to said charging circuits to recharge said capacitors after each discharge.

2. In an electric engine having a rotor comprising electromagnetic coil means roatatable within a stator comprising similar electromagnetic coil means, said electromagnetic coil means being polarised for magnetic repulsion;

Capacitor means electrically coupled across successive spark gaps to selected ones of said stator and all of the coils of said rotor;

Charging means connected to said capacitor means for charging said capacitor means to an electrical charge potential sufficient to cause arcing across said spark gaps to result in the discharge of said capacitor means through the electromagnetic coil means repel one another; and

A unidirectional electric power source connected to said charging means to energise said charging means to continue charging said capacitor means following each discharge whereby the rotor of said engine is maintained in rotation by the successive discharges of said capacitor means across successive spark gaps into said electromagnetic coil means.

3. An electric engine according to claim 2, wherein:

The charging means includes electronic square core oscillators connected to said unidirectional electric power source and includes step-up means and a rectifier to produce a substantial voltage step up from the voltage of said power source.

4. An electric engine according to claim 2, wherein:

The charging means includes a vibrator connected to said power source, and step-up transformer and rectifier means to provide a high voltage for charging said capacitor means.

5. A motive force-producing means comprising:

At least a first electromagnet means including at least one coil wound about a core,

At least a second electromagnet means including at least one coil wound about a core similar to said first core,

The respective cores being positioned adjacent to one another so that the magnetic polarities of the adjacent core surfaces are the same when a unidirectional electric current is passed through the coils,

At least one capacitor means having one terminal thereof connected to one terminal of both of said electromagnet coils,

The other terminal of said capacitor means being connected to one terminal of a spark gap means, the other terminals of the coils of both said first and said second electromagnet means being connected to the other terminal of said spark gap means,

At least one unidirectional pulse charging means connected to said capacitor means to charge said capacitor means to a relatively high potential sufficient to arc across said spark gap means at predetermined spacing of said gap terminals, and

A source of unidirectional potential connected to said charging circuit to energise said charging means,

Whereby upon application of current from said potential source to said charging means the successive pulses generated thereby charge said capacitor means to a voltage level sufficient to arc across said spark gap means to produce a discharge path for said capacitor means through said coils to cause said electromagnet means to repel one another with a substantial force.

6. A motive force-producing means according to claim 5, wherein:

Said first electromagnet means is secured in a relatively stable housing, and said second electromagnet means is connected with and freely movable relative to said stable housing, and has utilisation means connected thereto for performing work therewith when said capacitor means discharges through said coils of said electromagnet means.

7. A motive force-producing means according to claim 6, wherein said utilisation means is a motor rotor coupled with said second electromagnet means and said first electromagnet means is a stator.

8. A motive force-producing means according to claim 6, wherein said utilisation means is a piston attached to said second electromagnet means and is movable therewith to produce hammer-like blows when said capacitor means discharges through said electromagnet means.

9. In an electromotive force-generating system as disclosed, means for accelerating or decelerating the motion of a force-generating system, said means comprising:

At least two juxtaposed electromagnetic core elements, one fixed and one movable, including coils wound around it to provide a repulsion tendency when said cores are energised,

Spark gap terminals connected with said coils, Capacitor means connected with said spark gap terminals to discharge across said spark gap terminals through said coils when a charge of sufficient voltage level appears across said capacitor means, thus to energise said juxtaposed electromagnets to induce said juxtaposed electromagnet cores to repel one another,

Charging means connected to said capacitors for charging them to said sufficient voltage level, and selective positioning means coupled with said spark gap terminals and with at least said movable electromagnet core to cause selective displacement of said movable core with respect to said fixed core.

10. An electromotive force-generating system according to claim 9, wherein:

Said juxtaposed electromagnetic cores include a plurality of fixed cores and a smaller number of movable cores, said smaller number being an integral fraction of the number of fixed cores, and

Said selective positioning means is an electromagnetic clutch coupled with said smaller number of movable cores for movement therewith, and includes selective displacement means coupled with said spark gap terminals connected with said capacitors in said capacitor means and selected combinations of coils in said plurality of fixed electromagnets.

11. The method of generating motive power comprising the steps of:

a. positioning similar electromagnets in juxtaposed relationship with their respective cores arranged for repulsion when said electromagnets are energised,

b. charging capacitors to a relatively high potential, and

c. discharging said capacitors simultaneously through said electromagnets across spark gaps set to break down at said relatively high potential, thereby to cause said similar electromagnets to repel one another with considerable force.

12. The method of generating motive power defined in claim 11, wherein, in said positioning step at least one of said electromagnets is maintained in a fixed position and another electromagnet is free to move relative to said fixed electromagnet.

13. The method of generating motive power according to claim 11, wherein:

The charging step includes the charging of capacitors to a relatively high potential from a pulsed unipolar source of electrical energy.

14. in an electromagnetic capacitor discharge engine including movable electromagnets and fixed electromagnets, said movable electromagnets being movable into polar alignment with said fixed electromagnets, capacitor means, means for charging said capacitor means, and means for discharging said charged capacitor means through said fixed and movable electromagnets to polarise aligned fixed and movable electromagnets for magnetic repulsion, an acceleration and deceleration control means comprising:

First selective means for momentarily delaying the discharge of the capacitors until the movable electromagnets in said engine have begun to recede from the fixed electromagnets, in order to accelerate the motion of said movable electromagnets by the added impetus of the repulsion, and

Second selective means for momentarily accelerating the discharge of the capacitors to occur at a point in the motion of the movable electromagnets where said movable electromagnets are approaching said fixed electromagnets to decelerate the motion of said movable electromagnets by the tendency to repel the approaching electromagnets by the fixed electromagnets.

15. An electric engine, comprising:

Fixed electromagnets;

Movable electromagnets, movable into alignment with said fixed electromagnets;

Capacitor means;

Means for charging said capacitor means, and

Means for discharging said charged capacitor means through said fixed and movable electromagnets to polarise said aligned fixed and movable electromagnets for magnetic repulsion.

16. An electric engine as recited in claim 15, wherein: said means for discharging said charged capacitor means comprises voltage breakdown switch means.

17. An electric engine as recited in claim 16, wherein:

Said voltage breakdown switch means includes at least one terminal movable with at least one of said movable electromagnets for breaking down when said at least one of said movable electromagnets is in alignment with a said fixed electromagnet.

18. An electric engine as recited in claim 17, wherein:

Said voltage breakdown switch means comprises a spark gap means.

US Patent 4,595,975 June 17, 1986 Inventor: Edwin V. Gray snr.

EFFICIENT POWER SUPPLY SUITABLE FOR INDUCTIVE LOADS

Please note that this is a re-worded excerpt from this patent. It describes the circuitry used with Edwin Gray's power tube. Please be aware Edwin wanted at all costs, to conceal any useful technology while getting patents to encourage investors, so please understand that this patent is not intended to tell you how to make a working system of this type.

Fig.1 is a schematic circuit diagram of the electrical driving system.
Fig.2 is an elevational sectional view of the electrical conversion element.
Fig.3 is a plan sectional view taken along line 3--3 of Fig.2.
Fig.4 is a plan sectional view taken along line 4--4 of Fig.2.
Fig.5 is a schematic circuit diagram of the alternating-current input circuit.

SUMMARY OF THE INVENTION

The present invention provides a more efficient driving system comprising a source of electrical voltage; a vibrator connected to the low-voltage source for forming a pulsating signal; a transformer connected to the vibrator for receiving the pulsating signal; a high-voltage source, where available, connected to a bridge-type rectifier; or the bridge-type rectifier connected to the high voltage pulse output of the transformer; a capacitor for receiving the voltage pulse output; a conversion element having first and second anodes, electrically conductive means for receiving a charge positioned about the second anode and an output terminal connected to the charge receiving means, the second anode being connected to the capacitor; a commutator connected to the source of electrical voltage and to the first anode; and an inductive load connected to the output terminal whereby a high energy discharge between the first and second anodes is transferred to the charge receiving means and then to the inductive load.

As a sub-combination, the present invention also includes a conversion element comprising a housing; a first low voltage anode mounted to the housing, the first anode adapted to be connected to a voltage source; a second high voltage anode mounted to the housing, the second anode adapted to be connected to a voltage source; electrically conductive means positioned about the second anode and spaced therefrom for receiving a charge, the charge receiving means being mounted to the housing; and an output terminal communicating with the charge receiving means, said terminal adapted to be connected to an inductive load.

The invention also includes a method for providing power to an inductive load comprising the steps of providing a voltage source, pulsating a signal from said source; increasing the voltage of said signal; rectifying said signal; storing and increasing the signal; conducting said signal to a high voltage anode; providing a low voltage to a second anode to form a high energy discharge; electrostatically coupling the discharge to a charge receiving element; conducting the discharge to an inductive load; coupling a second capacitor to the load; and coupling the second capacitor to the source.

It is an aim of the present invention to provide a system for driving an inductive load which system is substantially more efficient than any now existing. Another object of the present invention is to provide a system for driving an inductive load which is reliable, is inexpensive and simply constructed.

The foregoing objects of the present invention together with various other objects, advantages, features and results thereof which will be evident to those skilled in the art in light of this disclosure may be achieved with the exemplary embodiment of the invention described in detail hereinafter and illustrated in the accompanying drawings.

DESCRIPTION OF THE PREFERRED EMBODIMENT

While the present invention is susceptible of various modifications and alternative constructions, an embodiment is shown in the drawings and will herein be described in detail. It should be understood however that it is not the intention to limit the invention to the particular form disclosed; but on the contrary, the invention is to cover all modifications, equivalents and alternative constructions falling within the spirit and scope of the invention as expressed in the appended claims.

There is disclosed herein an electrical driving system which, on theory, will convert low voltage electric energy from a source such as an electric storage battery to a high potential, high current energy pulse that is capable of developing a working force at the inductive output of the device that is more efficient than that which is capable of being developed directly from the energy source. The improvement in efficiency is further enhanced by the capability of the device to return that portion of the initial energy developed, and not used by the inductive load in the production of mechanical energy, to the same or second energy reservoir or source for use elsewhere, or for storage.

This system accomplishes the results stated above by harnessing the “electrostatic” or “impulse” energy created by a high-intensity spark generated within a specially constructed electrical conversion switching element tube. This element utilises a low-voltage anode, a high-voltage anode, and one or more “electrostatic” or charge receiving grids. These grids are of a physical size, and appropriately positioned, as to be compatible with the size of the tube, and therefore, directly related to the amount of energy to be anticipated when the device is operating.

The low-voltage anode may incorporate a resistive device to aid in controlling the amount of current drawn from the energy source. This low-voltage anode is connected to the energy source through a mechanical commutator or a solid-state pulser that controls the timing and duration of the energy spark within the element. The high-voltage anode is connected to a high- voltage potential developed by the associated circuits. An energy discharge occurs within the element when the external control circuits permit. This short duration, high-voltage, high-current energy pulse is captured by the “electrostatic” grids within the tube, stored momentarily, then transferred to the inductive output load.

The increase in efficiency anticipated in converting the electrical energy to mechanical energy within the inductive load is attributed to the utilisation of the most optimum timing in introducing the electrical energy to the load device, for the optimum period of time.

Further enhancement of energy conservation is accomplished by capturing a significant portion of the energy generated by the inductive load when the useful energy field is collapsing. This energy is normally dissipated in load losses that are contrary to the desired energy utilisation, and have heretofore been accepted because no suitable means had been developed to harness this energy and restore it to a suitable energy storage device.

The present invention is concerned with two concepts or characteristics. The first of these characteristics is observed with the introduction of an energising cur- rent through the inductor. The inductor creates a contrary force (counter-electromotive force or CEMP) that opposes the energy introduced into the inductor. This CEMF increases throughout the time the introduced energy is increasing.

In normal applications of an alternating-current to an inductive load for mechanical applications, the useful work of the inductor is accomplished prior to terminating the application of energy. The excess energy applied is thereby wasted.

Previous attempts to provide energy inputs to an inductor of time durations limited to that period when the optimum transfer of inductive energy to mechanical energy is occurring, have been limited by the ability of any such device to handle the high current required to optimise the energy transfer.

The second characteristic is observed when the energising current is removed from the inductor, As the current is decreased, the inductor generates an EMF that opposes the removal of current or, in other words, produces an energy source at the output of the inductor that simulates the original energy source, reduced by the actual energy removed from the circuit by the mechanical load. This “regenerated”, or excess, energy has previously been lost due to a failure to provide a storage capability for this energy.

In this invention, a high-voltage, high-current, short duration energy pulse is applied to the inductive load by the conversion element. This element makes possible the use of certain of that energy impressed within an arc across a spark-gap, without the resultant deterioration of circuit elements normally associated with high energy electrical arcs.

This invention also provides for capture of a certain portion of the energy induced by the high inductive kick produced by the abrupt withdrawal of the introduced current. This abrupt withdrawal of current is attendant upon the termination of the stimulating arc. The voltage spike so created is imposed upon a capacitor that couples the attendant current to a secondary energy storage device.

A novel, but not essential, circuit arrangement provides for switching the energy source and the energy storage device. This switching may be so arranged as to actuate automatically at predetermined times. The switching may be at specified periods determined by experimentation with a particular device, or may be actuated by some control device that measures the relative energy content of the two energy reservoirs.

FIG. 1

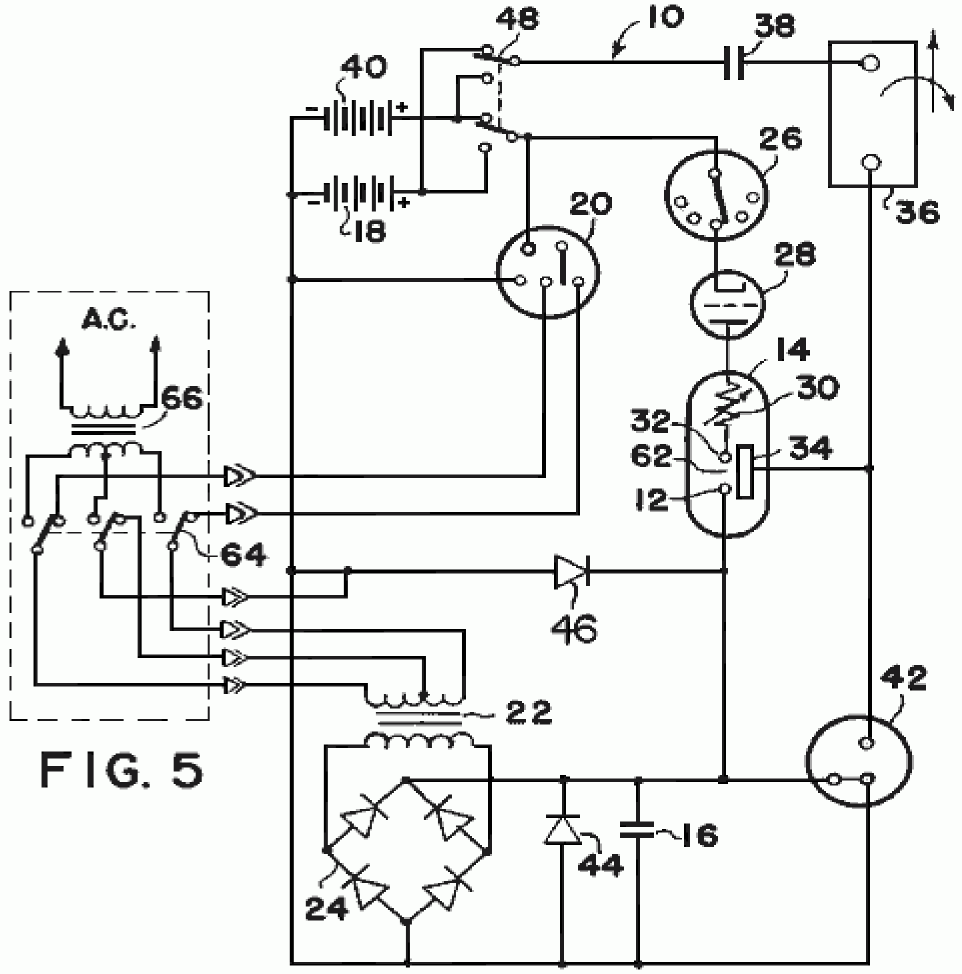

FIG. 5

Referring now to **Fig.1**, the system **10** will be described in additional detail. The potential for the high- voltage anode, **12** of the conversion element **14** is developed across the capacitor **16**. This voltage is produced by drawing a low current from a battery source **18** through the vibrator **20**. The effect of the vibrator is to create a pulsating input to the transformer **22**. The turns ratio of the transformer is chosen to optimise the volt- age applied to a bridge-type rectifier **24**. The output of the rectifier is then a series of high-voltage pulses of modest current. When the available source is already of the high voltage, AC type, it may be coupled directly to the bridge-type rectifier.

By repetitious application of these output pulses from the bridge-type rectifier to the capacitor **16**, a high-voltage, high-level charge is built up on the capacitor.

Control of the conversion switching element tube is maintained by a commutator **26**. A series of contacts mounted radially about a shafts or a solid-state switching device sensitive to time or other variable may be used for this control element. A switching element tube type one-way energy path **28** is introduced between the commutator device and the conversion switching element tube to prevent high energy arcing at the commutator current path. When the switching element tube is closed, current from the voltage source **18** is routed through a resistive element **30** and a low voltage anode **32**. This causes a high energy discharge between the anodes within the conversion switching element tube **14**.

The energy content of the high energy pulse is electrostatically coupled to the conversion grids **34** of the conversion element. This electrostatic charge is applied through an output terminal **60** (**Fig.2**) across the load inductance **36**, inducing a strong electromagnetic field about the inductive load. The intensity of this electromagnetic field is determined by the high electromotive potential developed upon the electrostatic grids and the very short time duration required to develop the energy pulse.

If the inductive load is coupled magnetically to a mechanical load, a strong initial torque is developed that may be efficiently utilised to produce physical work

Upon cessation of the energy pulse (arc) within the conversion switching element tube the inductive load is decoupled, allowing the electromagnetic field about the inductive load to collapse. The collapse of this energy field induces within the inductive load a counter EMF. This counter EMF creates a high positive potential across a second capacitor which, in turn, is induced into the second energy storage device or battery **40** as a charging current. The amount of charging current available to the battery 40 is dependent upon the initial conditions within the circuit at the time of discharge within the conversion switching element tube and the amount of mechanical energy consumed by the workload.

A spark-gap protection device **42** is included in the circuit to protect the inductive load and the rectifier elements from unduly large discharge currents. Should the potentials within the circuit exceed predetermined values, fixed by the mechanical size and spacing of the elements within the protective device, the excess energy is dissipated (bypassed) by the protective device to the circuit common (electrical ground).

Diodes **44** and **46** bypass the excess overshoot generated when the “Energy Conversion Switching Element Tube” is triggered. A switching element U allows either energy storage source to be used as the primary energy source, while the other battery is used as the energy retrieval unit. The switch facilitates interchanging the source and the retrieval unit at optimum intervals to be determined by the utilisation of the conversion switching element tube. This switching may be accomplished manually or automatically, as determined by the choice of switching element from among a large variety readily available for the purpose.

FIG. 2

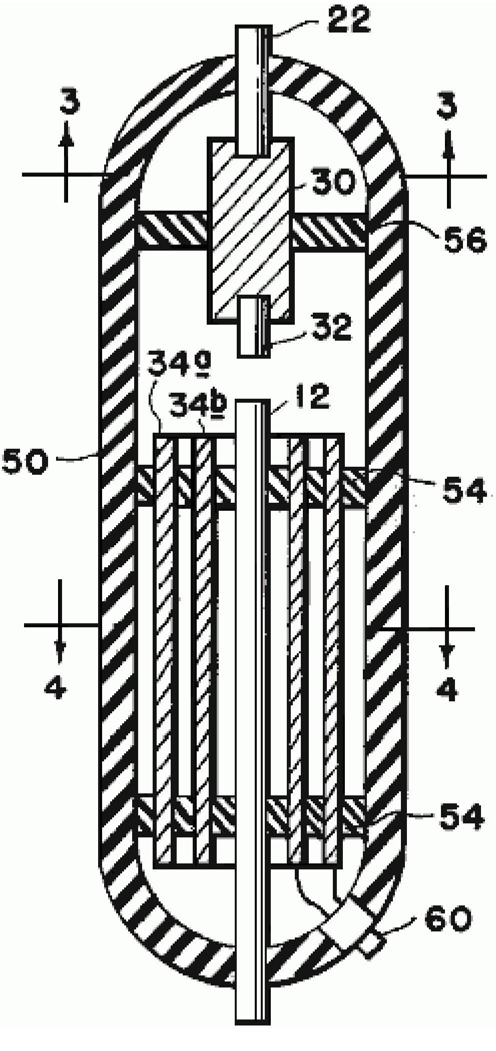

FIG. 3

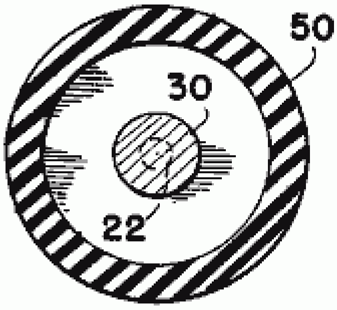

FIG. 4

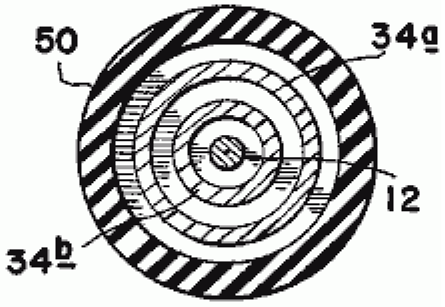

Fig.2, Fig.3, and **Fig.4** show the mechanical structure of the conversion switching element tube **14**. An outer housing **50** may be of any insulative material such as glass. The anodes **12** and **22** and grids **34a** and **34b** are firmly secured by nonconductive spacer material **54**, and **56**. The resistive element **30** may be introduced into the low-voltage anode path to control the peak currents through the conversion switching element tube. The resistive element may be of a piece, or it may be built of one or more resistive elements to achieve the desired result.

The anode material may be identical for each anode, or may be of differing materials for each anode, as dictated by the most efficient utilisation of the device, as determined by appropriate research at the time of production for the intended use. The shape and spacing of the electrostatic grids is also susceptible to variation with application (voltage, current, and energy requirements).

It is the contention of the inventor that by judicious mating of the elements of the conversion switching element tube, and the proper selection of the components of the circuit elements of the system, the desired theoretical results may be achieved. It is the inventor's contention that this mating and selection process is well within the capabilities of intensive research and development technique.

Let it be stated here that substituting a source of electric alternating-current subject to the required cur- rent and/or voltage shaping and/or timing, either prior to being considered a primary energy source, or there- after, should not be construed to change the described utilisation or application of primary energy in any way. Such energy conversion is readily achieved by any of a multitude of well established principles. The preferred embodiment of this invention merely assumes optimum utilisation and optimum benefit from this invention when used with portable energy devices similar in principle to the wet-cell or dry-cell battery.

This invention proposes to utilise the energy contained in an internally generated high-voltage electric spike (energy pulse) to electrically energise an inductive load.: this inductive load being then capable of converting the energy so supplied into a useful electrical or mechanical output.

In operation the high-voltage, short-duration electric spike is generated by discharging the capacitor **16** across the spark-gap in the conversion switching element tube. The necessary high-voltage potential is stored on the capacitor in incremental, additive steps from the bridge-type rectifier **24**. When the energy source is a direct-current electric energy storage device, such as the battery **12**, the input to the bridge rectifier is provided by the voltage step-up transformer **22**, that is in turn energised from the vibrator **20**, or solid-state chopper, or similar device to properly drive the transformer and rectifier circuits.

When the energy source is an alternating-current, switches **64** disconnect transformer **22** and the input to the bridge-type rectifier **24** is provided by the voltage step-up transformer **66**, that is in turn energised from the vibrator **20**, or solid-state chopper, or similar device to properly drive the transformer and rectifier circuits.

The repetitions output of the bridge rectifier incrementally increases the capacitor charge toward its maximum. This charge is electrically connected directly to the high-voltage anode **12** of the conversion switching element tube. When the low-voltage anode **32** is connected to a source of current, an arc is created in the spark-gap designated **62** of the conversion switching element tube equivalent to the potential stored on the high-voltage anode, and the current available from the low-voltage anode.

Because the duration of the arc is very short, the instantaneous voltage, and instantaneous current may both be very high. The instantaneous peak apparent power is therefore, also very high. Within the conversion switching element tube, this energy is absorbed by the grids **34a** and **34b** mounted circumferentially about the interior of the tube.

Control of the energy spike within the conversion switching element tube is accomplished by a mechanical, or solid-state commutator, that closes the circuit path from the low-voltage anode to the current source at that moment when the delivery of energy to the output load is most auspicious. Any number of standard high-accuracy, variable setting devices are available for this purpose. When control of the repetitive rate of the system's output is required, it is accomplished by controlling the time of connection at the low-voltage anode.

Thus there can be provided an electrical driving system having a low-voltage source coupled to a vibrator, a transformer and a bridge-type rectifier to provide a high voltage pulsating signal to a first capacitor. Where a high-voltage source is otherwise available, it may be coupled direct to a bridge-type rectifier, causing a pulsating signal to a first capacitor. The capacitor in turn is coupled to a high-voltage anode of an electrical conversion switching element tube. The element also includes a low-voltage anode which in turn is connected to a voltage source by a commutator, a switching element tube, and a variable resistor. Mounted around the high-voltage anode is a charge receiving plate which in turn is coupled to an inductive load to transmit a high-voltage discharge from the element to the load. Also coupled to the load is a second capacitor for storing the back EMF created by the collapsing electrical field of the load when the current to the load is blocked. The second capacitor in turn is coupled to the voltage source.

Patent GB 2,282,708 12th April 1995 Inventors: Harold Aspden (UK) and Robert George Adams (NZ)

ELECTRICAL MOTOR / GENERATOR

This version of the patent has been re-worded in an attempt to make it easier to read and understand. It describes the design of a pulsed electromagnet / permanent magnet motor which is capable of a higher power output than it’s own power input.

ABSTRACT

An electrodynamic motor-generator has a salient pole permanent magnet rotor interacting with salient stator poles to form a machine operating on the magnetic reluctance principle. The intrinsic ferromagnetic power of the magnets provides the drive torque by bringing the poles into register whilst current pulses demagnetise the stator poles as the poles separate. In as much as less power is needed for stator demagnetisation than is fed into the reluctance drive by the thermodynamic system powering the ferromagnetic state, the machine operates regeneratively by virtue of stator winding interconnection with unequal number of rotor and stator poles. A rotor construction is disclosed (**Fig.6** and **Fig.7**). The current pulse may be such as to cause repulsion of the rotor poles.

FIELD OF THE INVENTION

This invention relates to a form of electric motor which serves a generating function in that the machine can act regeneratively to develop output electrical power or can generate mechanical drive torque with unusually high efficiency in relation to electrical power input.

The field of invention is that of switched reluctance motors, meaning machines which have salient poles and operate by virtue of the mutual magnetic attraction and/or repulsion as between magnetised poles.

The invention particularly concerns a form of reluctance motor which incorporates permanent magnets to establish magnetic polarisation.

BACKGROUND OF THE INVENTION

There have been proposals in the past for machines in which the relative motion of magnets can in some way develop unusually strong force actions which are said to result in more power output than is supplied as electrical input.

By orthodox electrical engineering principles such suggestions have seemed to contradict accepted principles of physics, but it is becoming increasingly evident that conformity with the first law of thermodynamics allows a gain in the electromechanical power balance provided it is matched by a thermal cooling.

In this sense, one needs to extend the physical background of the cooling medium to include, not just the machine structure and the immediate ambient environment, but also the sub-quantum level of what is termed, in modern physics, the zero-point field. This is the field activity of the vacuum medium which exists in the space between atomic nuclei and atomic electrons and is the seat of the action which is that associated with the Planck constant. Energy is constantly being exchanged as between that activity and coextensive matter forms but normally these energy fluctuations preserve, on balance, an equilibrium condition so that this action passes unnoticed at the technology level.

Physicists are becoming more and more aware of the fact that, as with gravitation, so magnetism is a route by which we can gain access to the sea of energy that pervades the vacuum. Historically, the energy balance has been written in mathematical terms by assigning 'negative' potential to gravitation or magnetism. However, this is only a disguised way of saying that the vacuum field, suitably influenced by the gravitating mass of a body in the locality or by magnetism in a ferromagnet has both the capacity and an urge to shed energy.

Now, however, there is growing awareness of the technological energy generating potential of this field background and interest is developing in techniques for 'pumping' the coupling between matter and vacuum field to derive power from that hidden energy source. Such research may establish that this action will draw on the

2.7K cosmic background temperature of the space medium through which the Earth travels at some 400 km/s. The effect contemplated could well leave a cool 'vapour trail' in space as a machine delivering heat, or delivering a more useful electrical form of energy that will revert to heat, travels with body Earth through that space.

In pure physics terms, relevant background is of recent record in the August 1993 issue of Physical Review E, vol. 48, pp. 1562-1565 under the title: 'Extracting energy and heat from the vacuum', authored by D. C. Cole and H. E. Puthoff. Though the connection is not referenced in that paper, one of its author's presented experimental evidence on that theme at an April 1993 conference held in Denver USA. The plasma power generating device discussed at that conference was the subject of U. S. Patent No. 5,018,180, the inventor of record being K. R. Shoulders.

The invention, to be described below, operates by extracting energy from a magnetic system in a motor and the relevant scientific background to this technology can be appreciated from the teachings of E. B. Moullin, a Cambridge Professor of Electrical Engineering who was a President of the Institution of Electrical Engineers in U. K. That prior art will be described below as part of the explanation of the operation of the invention.

The invention presented here concerns specific structural design features of a machine adapted for robust operation, but these also have novelty and special merit in a functional operation. What is described is quite distinct from prior art proposals, one being a novel kind of motor proposed by Gareth Jones at a 1988 symposium held in Hull, Canada under the auspices of the Planetary Association for Clean Energy. Jones suggested the adaptation of an automobile alternator which generates three-phase AC for rectification and use as a power supply for the electrics in the automobile. This alternator has a permanent magnet rotor and Jones suggested that it could be used, with high efficiency gain and torque performance, by operating it as a motor with the three-phase winding circuit excited so as to promote strong repulsion between the magnet poles and the stator poles after the poles had come into register.

However, the Jones machine is not one exploiting the advantages of the invention to be described, because it is not strictly a reluctance motor having salient poles on both stator and rotor. The stator poles in the Jones machine are formed by the winding configuration in a slotted stator form, the many slots being uniformly distributed around the inner circumference of the stator and not constituting a pole system which lends itself to the magnetic flux actions to be described by reference to the E. B. Moullin experiment.

The Jones machine operates by generating a rotating stator field which, in a sense, pushes the rotor poles forward rather than pulling them in the manner seen in the normal synchronous motor. Accordingly, the Jones machine relies on the electric current excitation of the motor producing a field system which rotates smoothly but has a polarity pattern which is forced by the commutation control to keep behind the rotor poles in asserting a continuous repulsive drive.

Another prior art proposal which is distinguished from this invention is that of one of the applicants, H. Aspden, namely the subject of U.K. Patent No. 2,234,863 (counterpart U.S. Patent Serial No.4,975,608). Although this latter invention is concerned with extracting energy from the field by the same physical process as the subject invention, the technique for accessing that energy is not optimum in respect of the structure or method used. Whereas in this earlier disclosure, the switching of the reluctance drive excited the poles in their approach phase, the subject invention, in one of its aspects, offers distinct advantages by demagnetisation or reversal of magnetisation in the pole separation phase of operation.

There are unexpected advantages in the implementation proposed by the subject invention, inasmuch as recent research has confirmed that it requires less input power to switch off the mutual attraction across an air gap between a magnet and an electromagnet than it does to switch it on. Usually, in electromagnetism, a reversal symmetry is expected, arising from conventional teaching of the way forward and back magnetomotive forces govern the resulting flux in a magnetic circuit.

This will be further explained after describing the scope of the invention.

BRIEF DESCRIPTION OF THE INVENTION

According to one aspect of the invention, an electrodynamic motor/generator machine comprises a stator configured to provide a set of stator poles, a corresponding set of magnetising windings mounted on the stator pole set, a rotor having two sections each of which has a set of salient pole pieces, the rotor sections being axially spaced along the axis of rotation of the rotor, rotor magnetisation means disposed between the two rotor sections arranged to produce a unidirectional magnetic field which magnetically polarises the rotor poles, whereby the pole faces of one rotor section all have a north polarity and the pole faces of the other rotor section all have a south polarity and electric circuit connections between an electric current source and the stator magnetising windings arranged to regulate the operation of the machine by admitting current pulses for a duration determined according to the angular position of the rotor, which pulses have a direction tending to oppose the polarisation induced in the stator by the rotor polarisation as stator and rotor poles separate from an in-register position, whereby the action of the rotor magnetisation means provides a reluctance motor drive force to bring stator and rotor poles into register and the action of the stator magnetisation windings opposes the counterpart reluctance braking effect as the poles separate.

According to a feature of the invention, the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide demagnetisation of the stator poles as the stator and rotor poles separate from an in-register position.

In this regard it is noted that in order to suppress the reluctance drive torque or brake torque, depending upon whether poles are converging or separating, a certain amount of electrical power must be fed to the magnetising windings on the stator. In a sense these windings are really 'demagnetising windings' because the polarity of the circuit connections admit the pulse current in the demagnetising direction.

However, it is more usual to refer to windings on magnetic cores as 'magnetising windings' even though they can function as primary windings or secondary windings, the former serving the magnetisation function with input power and the latter serving a demagnetising function with return of power.

According to another feature of the invention, the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide a reversal of magnetic flux direction in the stator poles as the stator and rotor poles separate from an in-register position, whereby to draw on power supplied from the electric current source to provide additional forward drive torque.

According to a further feature of the invention, the electric current source connected to a stator magnetising winding of a first stator pole comprises, at least partially, the electrical pulses induced in the stator magnetising winding of a different second stator pole, the stator pole set configuration in relation to the rotor pole set configuration being such that the first stator pole is coming into register with a rotor pole as the second stator pole separates from its in-register position with a rotor pole.

This means that the magnetising windings of two stator poles are connected so that both serve a 'demagnetising' function, one in resisting the magnetic action of the mutual attraction in pulling poles into register, an action which develops a current pulse output and one in absorbing this current pulse, again by resisting the magnetic inter-pole action to demagnetise the stator pole as its associated rotor pole separates.

In order to facilitate the function governed by this circuit connection between stator magnetising windings, a phase difference is needed and this is introduced by designing the machine to have a different number of poles in a set of stator poles from the number of rotor poles in each rotor section. Together with the dual rotor section feature, this has the additional merit of assuring a smoother torque action and reducing magnetic flux fluctuations and leakage effects which contribute substantially to machine efficiency.

Thus, according to another feature of the invention, the stator configuration provides pole pieces which are common to both rotor sections in the sense that when stator and rotor poles are in-register the stator pole pieces constitute bridging members for magnetic flux closure in a magnetic circuit including that of the rotor magnetisation means disposed between the two rotor sections.

Preferably, the number of poles in a set of stator poles and the number of rotor poles in each section do not share a common integer factor, the number of rotor poles in one rotor section is the same as that in the other rotor section and the number of poles in a stator set and the number of poles in a rotor section differs by one, with the pole faces being of sufficient angular width to assure that the magnetic flux produced by the rotor magnetisation means can find a circular magnetic flux closure route through the bridging path of a stator pole and through corresponding rotor poles for any angular position of the rotor.

It is also preferable from a design viewpoint for the stator pole faces of this invention to have an angular width that is no greater than half the angular width of a rotor pole and for the rotor sections to comprise circular steel laminations in which the rotor poles are formed as large teeth at the perimeter with the rotor magnetisation means comprising a magnetic core structure the end faces of which abut two assemblies of such laminations forming the two rotor sections.

According to a further feature of the invention, the rotor magnetisation means comprises at least one permanent magnet located with its polarisation axis parallel with the rotor axis. The motor-generator may include an apertured metal disc that is of a non-magnetisable substance mounted on a rotor shaft and positioned intermediate the two rotor sections, each aperture providing location for a permanent magnet, whereby the centrifugal forces acting on the permanent magnet as the rotor rotates are absorbed by the stresses set up in the disc. Also, the rotor may be mounted on a shaft that is of a non-magnetisable substance, whereby to minimise magnetic leakage from the rotor magnetising means through that shaft.

According to another aspect of the invention, an electrodynamic motor-generator machine comprises a stator configured to provide a set of stator poles, a corresponding set of magnetising windings mounted on the stator pole set, a rotor having two sections each of which has a set of salient pole pieces, the rotor sections being axially spaced along the axis of rotation of the rotor, rotor magnetisation means incorporated in the rotor structure and arranged to polarise the rotor poles, whereby the pole faces of one rotor section all have a north polarity and the pole faces of the other rotor section all have a south polarity and electric circuit connections between an electric current source and the stator magnetising windings arranged to regulate the operation of the machine by admitting current pulses for a duration determined according to the angular position of the rotor, which pulses have a direction tending to oppose the polarisation induced in the stator by the rotor polarisation as stator and rotor poles separate from an in-register position, whereby the action of the rotor magnetisation means provides a reluctance motor drive force to bring stator and rotor poles into register and the action of the stator magnetisation windings opposes the counterpart reluctance braking effect as the poles separate.

According to a feature of this latter aspect of the invention, the electric current source connected to a stator magnetising winding of a first stator pole comprises, at least partially, the electrical pulses induced in the stator magnetising winding of a different second stator pole, the stator pole set configuration in relation to the rotor pole set configuration being such that the first stator pole is coming into register with a rotor pole as the second stator pole separates from its in-register position with a rotor pole.

BRIEF DESCRIPTION OF THE DRAWINGS

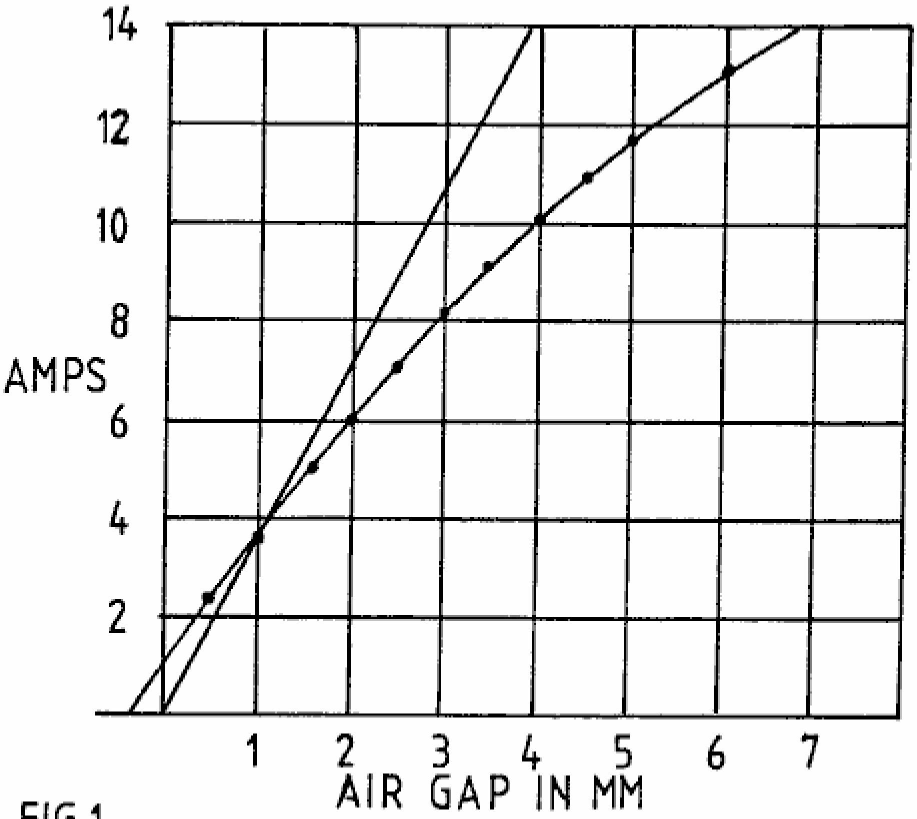

FIG.1

Fig.1 presents magnetic core test data showing how the volt-amp reactance power required to set up a constant magnetic flux action in an air gap, as assured by constant AC voltage excitation of a magnetising winding, falls short of the associated power of the potential implicit in the force action across that air gap.

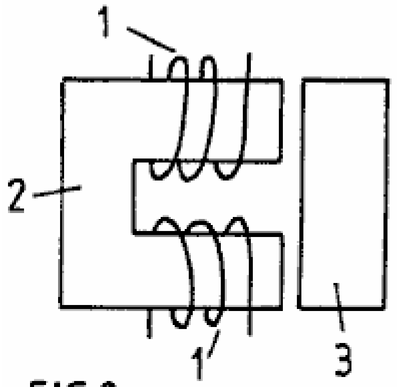

FIG.2

Fig.2 depicts the test structure to which Fig. 1 data applies.

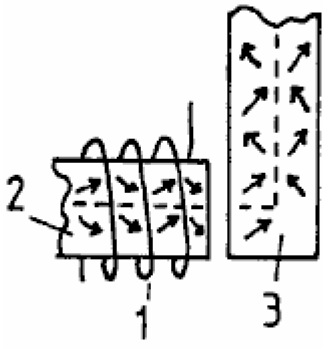

FIG.3

Fig.3 depicts the magnetisation action at work in causing magnetic flux to traverse an air-gap and turn a corner in a circuit through a magnetic core.

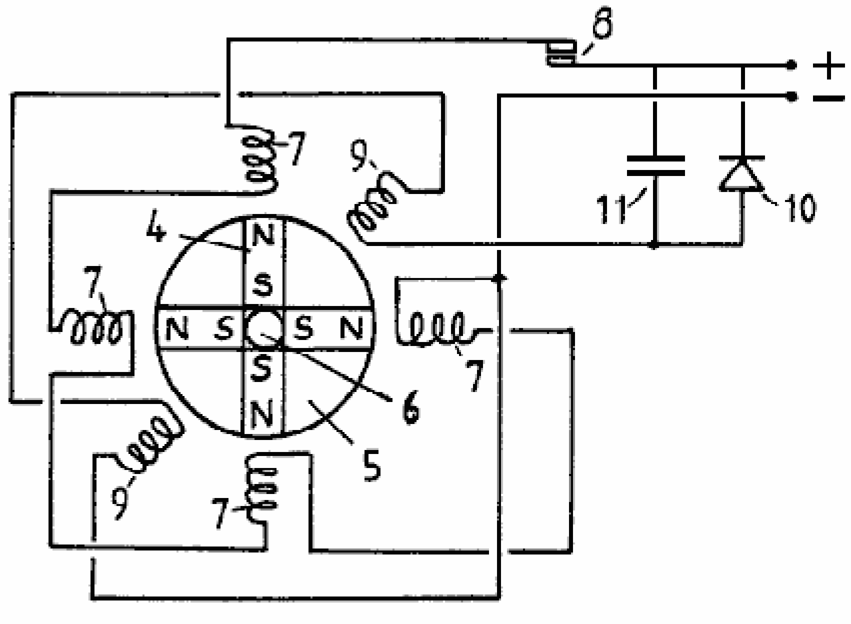

FIG. 4

Fig.4 shows the configuration of a test device used to prove the operating principles of the invention described.

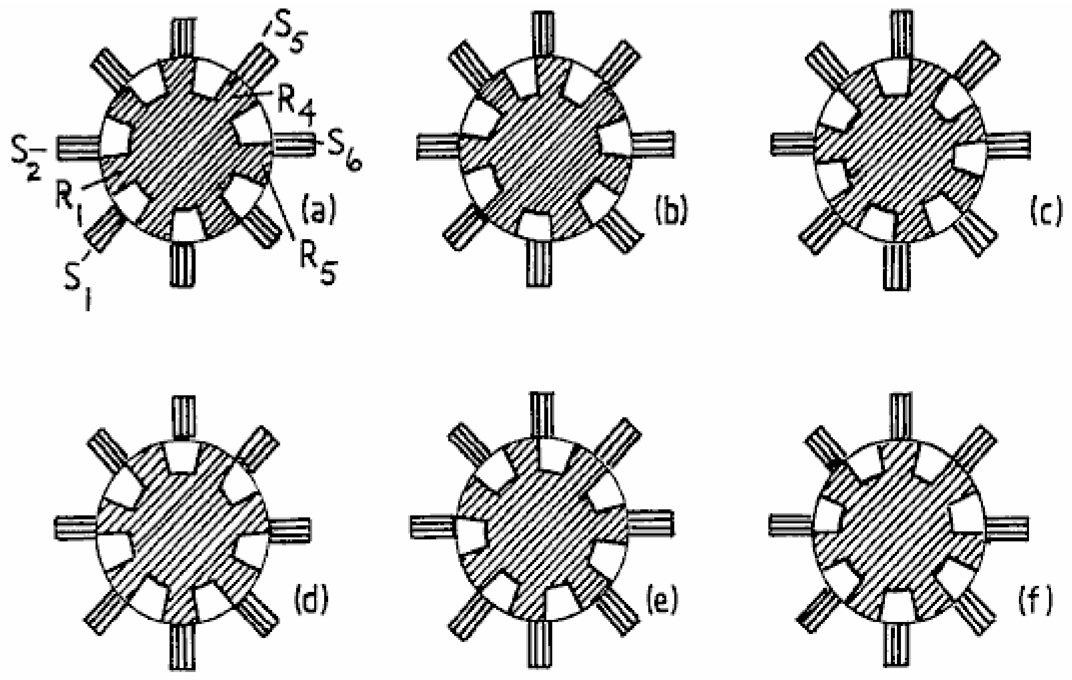

FIG.5

Fig.5 in its several illustrations depicts the progressive rotor pole to stator pole relationship as a rotor turns through a range of angular positions in a preferred embodiment of a machine according to the invention.

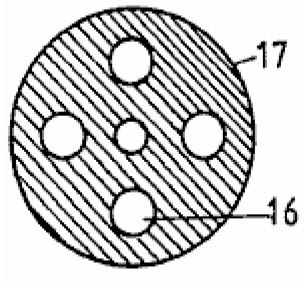

FIG. 6

Fig.6 shows the form of a disc member which provides location for four permanent magnets in the machine described.

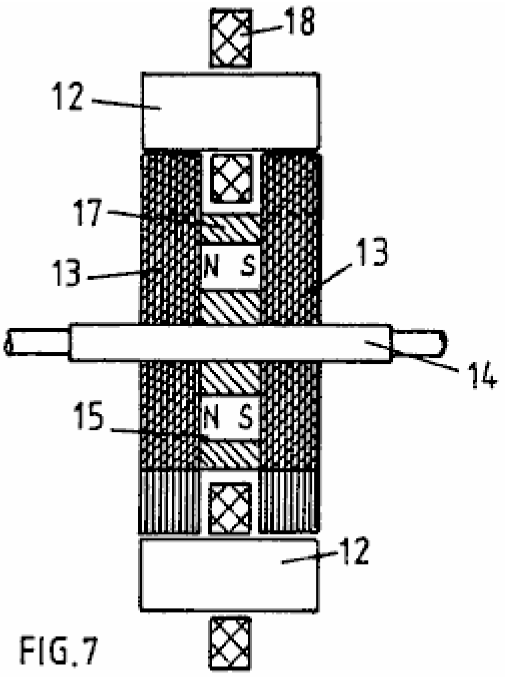

FIG.7

Fig.7 shows a cross-section of the magnetic circuit structure of a machine embodying the invention.

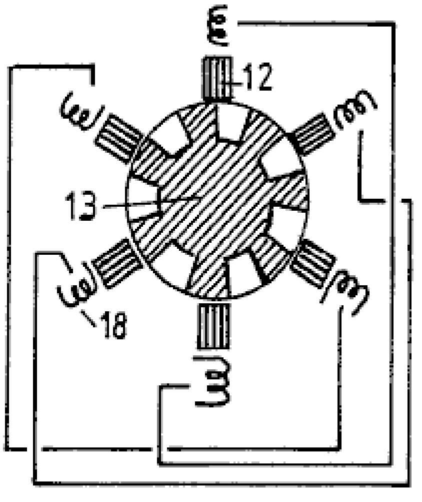

FIG.8

Fig.8 shows a six stator pole configuration with a seven pole rotor and depicts a schematic series connected linking of the magnetising windings of diametrically opposite stator poles.

DETAILED DESCRIPTION OF THE INVENTION

The fact that one can extract energy from the source which powers the intrinsic ferromagnetic state is not explicitly evident from existing textbooks, but it is implicit and, indeed, does become explicit once pointed out, in one textbook authored by E. B. Moullin. His book 'The Principles of Electromagnetism' published by Clarendon Press, Oxford (3rd Edition, 1955) describes on pages 168-174 an experiment concerned with the effect of air gaps between poles in a magnetic circuit. The data obtained are reproduced in **Fig.1**, where Professor Moullin shows a curve representing AC current input for different air gaps, given that the voltage supplied is constant. In the same figure, Moullin presents the theoretical current that would need to be applied to sustain the same voltage, and so the related pole forces across the air gap, assuming (a) no flux leakage and (b) that there is complete equality between inductive energy input and the mechanical energy potential for the magnetisation that is established in the air gap in a quarter-cycle period at the AC power excitation frequency.

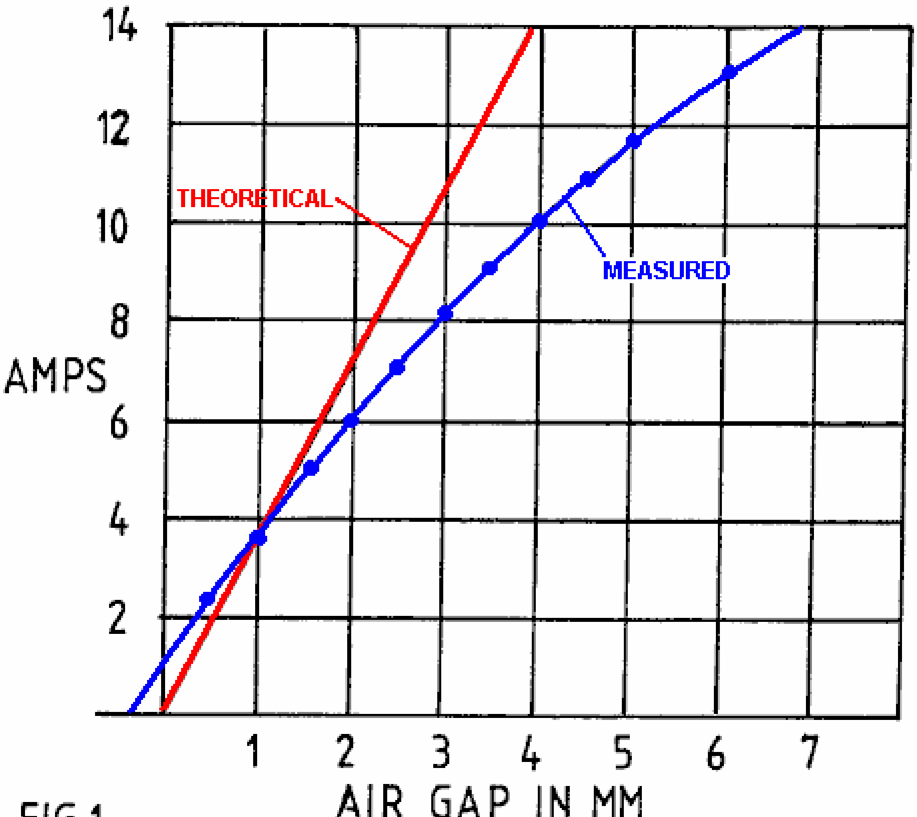

FIG.1

The data show that, even though the level of magnetic polarisation is well below the saturation value, being confined to a range that is regarded as the linear permeability range in transformer design, there is a clear drop-off of current, and so the volt-amp reactive power input needed, as current increases, compared with that predicted by the mechanical potential built up in the air gaps. Unless leakage flux is excessive, here was clear evidence of anomalous energy activity.

Moullin discusses the leakage flux inferred by this experiment but points out that there is considerable mystery in why the effect of a small gap, which should certainly not result in much flux leakage in the gap region, nevertheless has an enormous effect in causing what has to be substantial leakage in the light of the energy discrepancy. Moullin did not contemplate that energy had been fed in from the zero-point field system and so he left the issue with the statement that it was virtually impossible to predict leakage flux by calculation.

He was, of course, aware of magnetic domain structure and his argument was that the leakage flux problem was connected with what he termed a 'yawing' action of the flux as it passes around the magnetic circuit. Normally, provided the level of polarisation is below the knee of the B-H curve, which occurs at about 70% of saturation in iron cores of general crystal composition, it requires very little magnetising field to change the magnetic flux density. This is assuming that every effort is made to avoid air gaps. The action involves domain wall movements so that the magnetic states of adjacent domains switch to different crystal axes of easy magnetisation and this involves very little energy change.

However, if there is an air gap ahead in the flux circuit and the magnetising winding is not sitting on that air gap, the iron core itself has to be the seat of a progressive field source linking the winding and the gap. It can only serve in that sense by virtue of the lines of flux in the domains being forced to rotate somewhat from the preferred easy axes of magnetisation, with the help of the boundary surfaces around the whole core. This action means that, forcibly, and consequential upon the existence of the air gap, the flux must be carried through the core by that 'yawing' action. It means that substantial energy is needed to force the establishment of those fields within the iron core. More important, however, from the point of view of this invention, it means that the intrinsic magnetic polarisation effects in adjacent magnetic domains in the iron cease to be mutually parallel or orthogonal so as to stay directed along axes of easy magnetisation. Then, in effect, the magnetising action is not just that of the magnetising winding wrapped around the core but becomes also that of adjacent ferromagnetic polarisation as the latter act in concert as vacuum-energy powered solenoids and are deflected into one another to develop the additional forward magnetomotive forces.

The consequences of this are that the intrinsic ferromagnetic power source with its thermodynamic ordering action contributes to doing work in building up forces across the air gap. The task, in technological terms, is then to harness that energy as the gap is closed, as by poles coming together in a reluctance motor, and avoid returning that energy as the poles separate, this being possible if the controlling source of primary magnetisation is well removed from the pole gap and the demagnetisation occurs when the poles are at the closest position.

This energy situation is evident in the Moullin data, because the constant AC voltage implies a constant flux amplitude across the air gap if there is no flux leakage in the gap region. A constant flux amplitude implies a constant force between the poles and so the gap width in relation to this force is a measure of the mechanical energy potential of the air gap. The reactive volt-amp power assessment over the quarter-cycle period representing the polarisation demand can then be compared with the mechanical energy so made available. As already stated, this is how Moullin deduced the theoretical current curve. In fact, as his data show, he needed less current than the mechanical energy suggested and so he had in his experiment evidence of the vacuum energy source that passed unnoticed and is only now revealing itself in machines that can serve our energy needs.

In the research leading to this patent application the Moullin experiment has been repeated to verify a condition where a single magnetising winding serves three air gaps. The Moullin test configuration is shown in **Fig.2**, but in repeating the experiment in the research leading to this invention, a search coil was mounted on the bridging member and this was used to compare the ratio of the voltage applied to the magnetising winding and that induced in the search coil.

The same fall-off feature in current demand was observed, and there was clear evidence of substantial excess energy in the air gap. This was in addition to the inductive energy that necessarily had to be locked into the magnetic core to sustain the 'yawing' action of the magnetic flux already mentioned.

It is therefore emphasised that, in priming the flux 'yawing' action, energy is stored inductively in the magnetic core, even though this has been deemed to be the energy of flux leakage outside the core. The air gap energy is also induction energy. Both energies are returned to the source winding when the system is demagnetised, given a fixed air gap.

If, however, the air gap closes after or during magnetisation, much of that inductive energy goes into the mechanical work output. Note then that the energy released as mechanical work is not just that stored in the air gap but is that stored in sustaining the 'yaw'. Here, then is reason to expect an even stronger contribution to the dynamic machine performance, one that was not embraced by the calculation of the steady-state situation.

Given the above explanation of the energy source, the structural features which are the subject of this invention will now be described.

The 'yawing' action is depicted in **Fig.3**, which depicts how magnetic flux navigates a right-angled bend in a magnetic core upon passage through an air gap. By over-simplification it is assumed that the core has a crystal structure that has a preferred axis of magnetisation along the broken line path. With no air gap, the current needed by a magnetising winding has only to provide enough magnetomotive force to overcome the effects of non-magnetic inclusions and impurities in the core substance and very high magnetic permeabilities can apply. However, as soon as the air gap develops, this core substance has to find a way of setting up magnetomotive force in regions extending away from the locality of the magnetising winding. It cannot do this unless its effect is so powerful that the magnetic flux throughout the magnetic circuit through the core substance is everywhere deflected from alignment with a preferred easy axis of magnetisation. Hence the flux vectors depicted by the arrows move out of alignment with the broken line shown.

There is a 'knock-on' effect progressing all the way around the core from the seat of the magnetising winding and, as already stated, this harnesses the intrinsic ferromagnetic power that, in a system with no air gap, could only be affected by magnetisation above the knee of the B-H curve. Magnetic flux rotation occurs above that knee, whereas in an ideal core the magnetism develops with very high permeability over a range up to that knee, because it needs very little power to displace a magnetic domain wall sideways and promote a 900 or a1800 flux reversal. Indeed, one can have a magnetic permeability of 10,000 below the knee and 100 above the knee, the latter reducing progressively until the substance saturates magnetically.

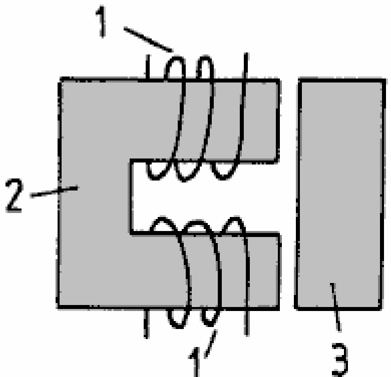

FIG.2

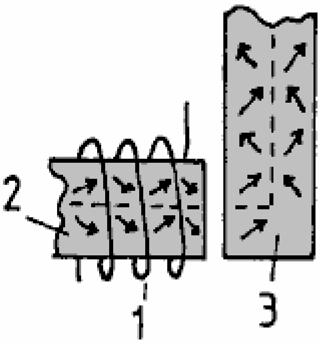

FIG.3

In the situation depicted in **Fig.2** and **Fig.3** the field strength developed by the magnetising windings **1** on magnetic core **2** has to be higher, the greater the air gap, in order to achieve the same amount of magnetisation as measured by the voltage induced in a winding (not shown) on the bridging member **3**. However, by virtue of that air gap there is potential for harnessing energy supplied to that air gap by the intrinsic zero-point field that accounts for the magnetic permeability being over unity and here one can contemplate very substantial excess energy potential, given incorporation in a machine design which departs from convention.

One of the applicants has built an operative test machine which is configured as depicted schematically in **Fig.4**. The machine has been proved to deliver substantially more mechanical power output than is supplied as electrical input, as much as a ratio of 7:1 in one version, and it can act regeneratively to produce electrical power.

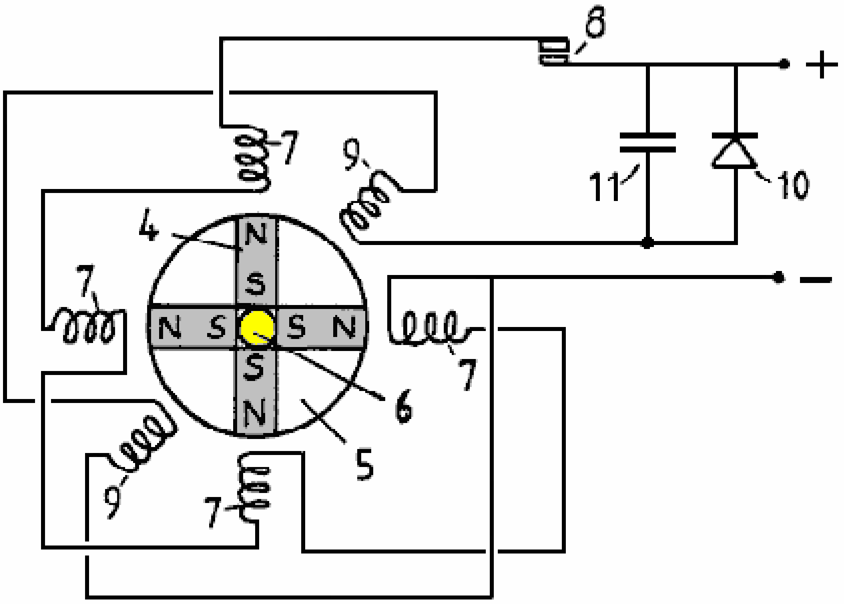

FIG. 4

What is shown in **Fig.4** is a simple model designed to demonstrate the principle of operation. It comprises a rotor in which four permanent magnets **4** are arrayed to form four poles. The magnets are bonded into four sectors of a non-magnetic disc **5** using a high density polyurethane foam filler and the composite disc is then assembled on a brass spindle **6** between a split flange coupling. Not shown in the figure is the structure holding the spindle vertically in bearings or the star wheel commutator assembly attached to the upper shaft of the spindle.

Note that the magnets present north poles at the perimeter of the rotor disc and that the south poles are held together by being firmly set in the bonding material. A series of four stator poles were formed using magnetic cores from standard electromagnetic relays are were positioned around the rotor disc as shown. The magnetising windings **7** on these cores are shown to be connected in series and powered through commutator contacts **8** by a DC power supply. Two further stator cores formed by similar electromagnetic relay components are depicted by their windings **9** in the intermediate angle positions shown and these are connected in series and connected to a rectifier **10** bridged by a capacitor **11**.

The rotor spindle **6** is coupled with a mechanical drive (not shown) which harnesses the torque developed by the motor thus formed and serves as a means for measuring output mechanical power delivered by the machine.

In operation, assuming that the rotor poles are held initially off-register with the corresponding stator poles and the hold is then released, the strong magnetic field action of the permanent magnets will turn the rotor to bring the stator and rotor poles into register. A permanent magnet has a strong attraction for soft iron and so this initial impulse of rotation is powered by the potential energy of the magnets.

Now, with the rotor acting as a flywheel and having inertia it will have a tendency to over-shoot the in-register pole position and that will involve a reverse attraction with the result that the rotor will oscillate until damping action brings it to rest. However, if the contacts of the commutating switch are closed as the poles come

The commutating switch **8** needs only to be closed for a limited period of angular travel following the top dead centre in-register position of the stator and rotor poles. The power supplied through that switch by those pulses will cause the rotor to continue rotating and high speeds will be achieved as the machine develops its full motor function.

Tests on such a machine have shown that more mechanical power can be delivered than is supplied electrically by the source powering the action through the commutating switch. The reason for this is that, whereas the energy in the air gap between rotor and stator poles which is tapped mechanically as the poles come into register is provided by the intrinsic power of the ferromagnet, a demagnetising winding on the part of the core system coupled across that air gap needs very little power to eliminate the mechanical force acting across that air gap. Imagine such a winding on the bridging member shown in **Fig.2**. The action of current in that winding, which sits astride the 'yawing' flux in that bridging member well removed from the source action of the magnetising windings **1**, is placed to be extremely effective in resisting the magnetising influence communicated from a distance. Hence very little power is needed to overcome the magnetic coupling transmitted across the air gap.

Although the mutual inductance between two spaced-apart magnetising windings has a reciprocal action, regardless of which winding is primary and which is secondary, the action in the particular machine situation being described involves the 'solenoidal' contribution represented by the 'yawing' ferromagnetic flux action. The latter is not reciprocal inasmuch as the flux ‘yaw' depends on the geometry of the system. A magnetising winding directing flux directly across an air gap has a different influence on the action in the ferromagnetic core from one directing flux lateral to the air gap and there is no reciprocity in this action.

In any event, the facts of experiment do reveal that, owing to a significant discrepancy in such mutual interaction, more mechanical power is fed into the rotor than is supplied as input from the electrical source.

This has been further demonstrated by using the two stator windings **9** to respond in a generator sense to the passage of the rotor poles. An electrical pulse is induced in each winding by the passage of a rotor pole and this is powered by the inertia of the rotor disc **5**. By connecting the power so generated, to charge the capacitor **11,** the DC power supply can be augmented to enhance the efficiency even further.

Indeed, the machine is able to demonstrate the excess power delivery from the ferromagnetic system by virtue of electrical power generation charging a battery at a greater rate than a supply battery is discharged.

This invention is concerned with a practical embodiment of the motor-generator principles just described and aims, in its preferred aspect, to provide a robust and reliable machine in which the tooth stresses in the rotor poles, which are fluctuating stresses communicating high reluctance drive torque, are not absorbed by a ceramic permanent magnet liable to rupture owing to its brittle composition.

Another object is to provide a structure which can be dismantled and reassembled easily to replace the permanent magnets, but an even more important object is that of minimising the stray leakage flux oscillations from the powerful permanent magnets. Their rotation in the device depicted in **Fig.4** would cause excessive eddy-current induction in nearby metal, including that of the machine itself, and such effects are minimised if the flux changes are confined to paths through steel laminations and if the source flux from the magnets has a symmetry or near symmetry about the axis of rotation.

Thus, the ideal design with this in mind is one where the permanent magnet is a hollow cylinder located on a non-magnetic rotor shaft, but, though that structure is within the scope of this invention, the machine described will utilise several separate permanent magnets approximating, in function, such a cylindrical configuration.

Referring to **Fig.4**, it will further be noted that the magnetic flux emerging from the north poles will have to find its way along leakage paths through air to re-enter the south poles. For periods in each cycle of machine operation the flux will be attracted through the stator cores, but the passage through air is essential and so the power of the magnets is not used to full advantage and there are those unwanted eddy-current effects.

To overcome this problem the invention provides for two separate rotor sections and the stator poles become bridging members, which with optimum design, allow the flux from the magnets to find a route around a magnetic circuit with minimal leakage through air as the flux is directed through one or other pairs of air gaps where the torque action is developed.

FIG.5

Reference is now made to **Fig.5** and the sequence of rotor positions shown. Note that the stator pole width can be significantly smaller that that of the rotor poles. Indeed, for operation using the principles of this invention, it is advantageous for the stator to have a much smaller pole width so as to concentrate the effective pole region. A stator pole width of half that of the rotor is appropriate but it may be even smaller and this has the secondary advantage of requiring smaller magnetising windings and so saving on the loss associated with the current circuit.

FIG.7

FIG. 6

The stator has eight pole pieces formed as bridging members **12**, more clearly represented in **Fig.7**, which shows a sectional side view through two rotor sections **13** axially spaced on a rotor shaft **14**. There are four permanent magnets **15** positioned between these rotor sections and located in apertures **16** in a disc **17** of a non-magnetic substance of high tensile strength, the latter being shown in **Fig.6**. The rotor sections are formed from disc laminations of electrical steel which has seven large teeth, the salient poles. Magnetising windings **18** mounted on the bridging members **12** constitute the system governing the action of the motor-generator being described.

The control circuitry is not described as design of such circuitry involves ordinary skill possessed by those involved in the electrical engineering art.

It suffices, therefore, to describe the merits of the structural design configuration of the core elements of the machine. These concern principally the magnetic action and, as can be imagined from **Fig.7**, the magnetic flux from the magnets enters the rotor laminations by traversing the planar faces of the laminations and being deflected into the plane of the laminations to pass through one or other of the stator pole bridging members, returning by a similar route through the other rotor.

By using eight stator poles and seven rotor poles, the latter having a pole width equal to half the pole pitch in an angular sense, it will be seen from **Fig.5**, that there is always a flux passage across the small air gap between stator and rotor poles. However, as one pole combination is in-register the diametrically-opposed pole combinations are out-of register.

As described by reference to **Fig.4** the operation of the machine involves allowing the magnet to pull stator and rotor poles into register and then, as they separate, pulsing the winding on the relevant stator member to demagnetise that member. In the **Fig.4** system, all the stator magnetising windings were pulsed together, which is not an optimum way in which to drive a multi-pole machine.

In the machine having the pole structure with one less rotor pole than stator poles (or an equivalent design in which there is one less stator pole than rotor poles) this pulsing action can be distributed in its demand on the power supply, and though this makes the commutation switch circuit more expensive the resulting benefit outweighs that cost. However, there is a feature of this invention by which that problem can be alleviated if not eliminated.

Suppose that the rotor has the position shown in **Fig.5(a)** with the rotor pole denoted **R1** midway between stator poles **S1** and **S2** and imagine that this is attracted towards the in-register position with stator pole **S2**. Upon reaching that in-register position, as shown in **Fig.5(c)**, suppose that the magnetising winding of stator pole **S2** is excited by a current pulse which is sustained until the rotor reaches the **Fig.5(e)** position.

The combination of these two actions will have imparted a forward drive impulse powered by the permanent magnet in the rotor structure and the current pulse which suppresses braking action will have drawn a smaller amount of energy from the electrical power source which supplies it. This is the same process as was described by reference to **Fig.4**.

However, now consider the events occurring in the rotor action diametrically opposite that just described. In the **Fig.5(a)** position rotor pole **R4** has come fully into register with stator pole **S5** and so stator pole **S5** is ready to be demagnetised. However, the magnetic coupling between the rotor and stator poles is then at its strongest. Note, however, that in that **Fig.5(a)** position **R5** is beginning its separation from stator poles and the magnetising winding of stator pole **S6** must then begin draw power to initiate demagnetisation. During that following period of pole separation the power from the magnet is pulling **R1** and **S2** together with much more action than is needed to generate that current pulse needed to demagnetise **S6**. It follows, therefore, that, based on the research findings of the regenerative excitation in the test system of **Fig.4**, the series connection of the magnetising windings on stators **S2** and **S6** will, without needing any commutative switching, provide the regenerative power needed for machine operation.

The complementary action of the two magnetising windings during the pole closure and pole separation allows the construction of a machine which, given that the zero-point vacuum energy powering the ferromagnet is feeding input power, will run on that source of energy and thereby cool the sustaining field system.

There are various design options in implementing what has just been proposed. Much depends upon the intended use of the machine. If it is intended to deliver mechanical power output the regenerative electrical power action can all be used to power the demagnetisation with any surplus contributing to a stronger drive torque by reversing the polarity of the stator poles during pole separation.

If the object is to generate electricity by operating in generator mode then one could design a machine having additional windings on the stator for delivering electrical power output. However, it seems preferable to regard the machine as a motor and maximise its efficiency in that capacity whilst using a mechanical coupling to an alternator of conventional design for the electrical power generation function.

In the latter case it would still seem preferable to use the self-excitation feature already described to reduce commutation switching problems.

The question of providing for machine start-up can be addressed by using a separate starter motor powered from an external supply or by providing for current pulsing limited to, say, two stator poles. Thus, for example, with the eight stator pole configuration, the cross-connected magnetising windings could be limited to three stator pairs, with two stator magnetising windings left free for connection to a pulsed external supply source.

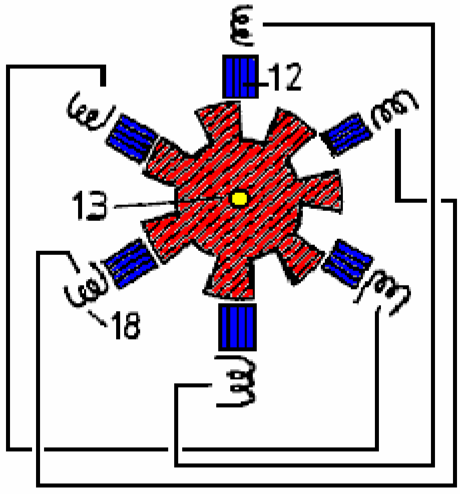

FIG.8

If the latter feature were not required, then the stator magnetising windings would all be connected in pairs on a truly diametrically opposite basis. Thus **Fig.8** shows a rotor-stator configuration having six stator poles interacting with seven rotor poles and stator magnetising windings linked together in pairs.

The invention, therefore, offers a wide range of implementation possibilities, which, in the light of this disclosure will become obvious to persons skilled in the electrical engineering art, all based, however, on the essential but simple principle that a rotor has a set of poles of common polarity which are attracted into register with a set of stator poles that are suppressed or reversed in polarity magnetically during pole separation. The invention, however, also offers the important feature of minimising commutation and providing further for a magnetic flux closure that minimises the leakage flux and fluctuations of leakage flux and so contributes to efficiency and high torque performance as well as durability and reliability of a machine incorporating the invention.

It is noted that although a machine has been described which uses two rotor sections it is possible to build a composite version of the machine having several rotor sections. In the eventuality that the invention finds use in very large motor-generator machines the problem of providing very large magnets can be overcome by a design in which numerous small magnets are assembled. The structural concept described by reference to **Fig.6** in providing locating apertures to house the magnets makes this proposal highly feasible. Furthermore, it is possible to replace the magnets by a steel cylinder and provide a solenoid as part of the stator structure and located between the rotor sections. This would set up an axial magnetic field magnetising the steel cylinder and so polarising the rotor. However, the power supplied to that solenoid would detract from the power generated and so such a machine would not be as effective as the use of permanent magnets such as are now available.

Nevertheless, should one see significant progress in the development of warm superconductor materials, it may become feasible to harness the self-generating motor-generator features of the invention, with its self-cooling properties, by operating the device in an enclosure at low temperatures and replacing the magnets by a superconductive stator supported solenoid.

CLAIMS

1. An electrodynamic motor-generator machine comprising a stator configured to provide a set of stator poles, a corresponding set of magnetising windings mounted on the stator pole set, a rotor having two sections each of which has a set of salient pole pieces, the rotor sections being axially spaced along the axis of rotation of the rotor, rotor magnetisation means disposed between the two rotor sections arranged to produce a unidirectional magnetic field which magnetically polarises the rotor poles, whereby the pole faces of one rotor section all have a north polarity and the pole faces of the other rotor section all have a south polarity and electric circuit connections between an electric current source and the stator magnetising windings arranged to regulate the operation of the machine by admitting current pulses for a duration determined according to the angular position of the rotor, which pulses have a direction tending to oppose the polarisation induced in the stator by

the rotor polarisation as stator and rotor poles separate from an in-register position, whereby the action of the rotor magnetisation means provides a reluctance motor drive force to bring stator and rotor poles into register and the action of the stator magnetisation windings opposes the counterpart reluctance braking effect as the poles separate.

2. A motor-generator according to claim 1, wherein the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide demagnetisation of the stator poles as the stator and rotor poles separate from an in-register position.

3. A motor-generator according to claim 1, wherein the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide a reversal of magnetic flux direction in the stator poles as the stator and rotor poles separate from an in-register position, whereby to draw on power supplied from the electric current source to provide additional forward drive torque.

4. A motor-generator according to claim 1, wherein the electric current source connected to a stator magnetising winding of a first stator pole comprises, at least partially, the electrical pulses induced in the stator magnetising winding of a different second stator pole, the stator pole set configuration in relation to the rotor pole set configuration being such that the first stator pole is coming into register with a rotor pole as the second stator pole separates from its in-register position with a rotor pole.

5. A motor-generator according to claim 1, wherein the number of poles in a set of stator poles is different from the number of rotor poles in each rotor section.

6. A motor-generator according to claim 1, wherein the stator configuration provides pole pieces which are common to both rotor sections in the sense that when stator and rotor poles are in-register the stator pole pieces constitute bridging members for magnetic flux closure in a magnetic circuit including that of the rotor magnetisation means disposed between the two rotor sections.

7. A motor-generator according to claim 6, wherein the number of poles in a set of stator poles and the number of rotor poles in each section do not share a common integer factor and the number of rotor poles in one rotor section is the same as that in the other rotor section.

8. A motor-generator according to claim 7, wherein the number of poles in a stator set and the number of poles in a rotor section differs by one and the pole faces are of sufficient angular width to assure that the magnetic flux produced by the rotor magnetisation means can find a circuital magnetic flux closure route through the bridging path of a stator pole and through corresponding rotor poles for any angular position of the rotor.

9. A motor-generator according to claim 8, wherein each rotor section comprises seven poles.

10. A motor-generator according to claim 7, wherein there are N rotor poles in each rotor section and each has an angular width that is 180/N degree of angle.

11. A motor-generator according to claim 7, wherein the stator pole faces have an angular width that is no greater than half the angular width of a rotor pole.

12. A motor-generator according to claim 1, wherein the rotor sections comprise circular steel laminations in which the rotor poles are formed as large teeth at the perimeter, and the rotor magnetisation means comprise a magnetic core structure the end faces of which abut two assemblies of such laminations forming the two rotor sections.

13. A motor-generator according to claim 1 in which the rotor magnetisation means comprises at least one permanent magnet located with its polarisation axis parallel with the rotor axis.

14. A motor-generator according to claim 13, wherein an apertured metal disc that is of a non-magnetisable substance is mounted on a rotor shaft and positioned intermediate the two rotor sections and each aperture provides location for a permanent magnet, whereby the centrifugal forces acting on the permanent magnet as the rotor rotates are absorbed by the stresses set up in the disc.

15. A motor-generator according to claim 1, having a rotor mounted on a shaft that is of a non-magnetisable substance, whereby to minimise magnetic leakage from the rotor magnetising means.

16. An electrodynamic motor-generator machine comprising a stator configured to provide a set of stator poles, a corresponding set of magnetising windings mounted on the stator pole set, a rotor having two sections each of which has a set of salient pole pieces, the rotor sections being axially spaced along the axis of rotation of the

rotor, rotor magnetisation means incorporated in the rotor structure and arranged to polarise the rotor poles, whereby the pole faces of one rotor section all have a north polarity and the pole faces of the other rotor section all have a south polarity and electric circuit connections between an electric current source and the stator magnetising windings arranged to regulate the operation of the machine by admitting current pulses for a duration determined according to the angular position of the rotor, which pulses have a direction tending to oppose the polarisation induced in the stator by the rotor polarisation as stator and rotor poles separate from an in-register position, whereby the action of the rotor magnetisation means provides a reluctance motor drive force to bring stator and rotor poles into register and the action of the stator magnetisation windings opposes the counterpart reluctance braking effect as the poles separate.

17. A motor-generator according to claim 16, wherein the electric current source connected to a stator magnetising winding of a first stator pole comprises, at least partially, the electrical pulses induced in the stator magnetising winding of a different second stator pole, the stator pole set configuration in relation to the rotor pole set configuration being such that the first stator pole is coming into register with a rotor pole as the second stator pole separates from its in-register position with a rotor pole.

Amendments to the claims have been filed as follows 1. An electrodynamic motor-generator machine comprising a stator configured to provide a set of stator poles, a corresponding set of magnetising windings mounted on the stator pole set, a rotor having two sections each of which has a set of salient pole pieces, the rotor sections being axially spaced along the axis of rotation of the rotor, rotor magnetisation means disposed between the two rotor sections arranged to produce a unidirectional magnetic field which magnetically polarises the rotor poles, whereby the pole faces of one rotor section all have a north polarity and the pole faces of the other rotor section all have a south polarity and electric circuit connections between an electric current source and the stator magnetising windings arranged to regulate the operation of the machine by admitting current pulses for a duration determined according to the angular position of the rotor, which pulses have a direction tending to oppose the polarisation induced in the stator by the rotor polarisation as stator and rotor poles separate from an in-register position, whereby the action of the rotor magnetisation means provides a reluctance motor drive force to bring stator and rotor poles into register and the action of the stator magnetisation windings opposes the counterpart reluctance braking effect as the poles separate, the machine being characterised in that the stator comprises separate ferromagnetic bridging members mounted parallel with the rotor axis, the ends of which constitute stator poles and the core sections of which provide closure paths operative when the stator and rotor poles are in register to confine magnetic flux developed by the rotor magnetisation means to a stator flux path of restricted cross-section disposed anti-parallel with the unidirectional magnetic field polarisation axis of the rotor magnetising means 2. A motor-generator according to claim 1, wherein the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide demagnetisation of the stator poles as the stator and rotor poles separate from an in-register position.

3. A motor-generator according to claim 1, wherein the circuit connecting the electric current source and the stator magnetising windings is designed to deliver current pulses which are of sufficient strength and duration to provide a reversal of magnetic flux direction in the stator poles as the stator and rotor poles separate from an in-register position, whereby to draw on power supplied from the electric current source to provide additional forward drive torque.

4. A motor-generator according to claim 1, wherein the electric current source connected to a stator magnetising winding of a first stator pole comprises, at least partially, the electrical pulses induced in the stator magnetising winding of a different second stator pole, the stator pole set configuration in relation to the rotor pole set configuration being such that the first stator pole is coming into register with a rotor pole as the second stator pole separates from its in-register position with a rotor pole.

5. A motor-generator according to claim 1, wherein the number of poles in a set of stator poles is different from the number of rotor poles in each rotor section.

6. A motor-generator according to claim 1, wherein the stator configuration provides pole pieces which are common to both rotor sections in the sense that when stator and rotor poles are in-register the stator pole pieces constitute bridging members for magnetic flux closure in a magnetic circuit including that of the rotor magnetisation means disposed between the two rotor sections.

7. A motor-generator according to claim 6, wherein the number of poles in a set of stator poles and the number of rotor poles in each section do not share a common integer factor and the number of rotor poles in one rotor section is the same as that in the other rotor section.

WILLIAM BARBAT: POWER GENERATOR

Patent Application US 2007/0007844 A1 11th January 2007 Inventor: William N. Barbat

SELF-SUSTAINING ELECTRIC POWER GENERATOR UTILISING ELECTRONS OF LOW INERTIAL MASS TO MAGNIFY INDUCTIVE ENERGY

This patent application shows a very neat, self-powered electrical generator with a theoretical output of anything up to a COP of 59 when using cadmium selenide. The discussion of the theoretical aspects of the design includes a large amount of historical information and it covers the origin of the "law" of Conservation of Energy which, in spite of being incorrect, has been for decades, a major obstacle to the scientific development of free-energy devices.

Filed: 6th March 2006
Assignee: Levitronics, Inc.
Provisional application No. 60/697,729 filed on 8th July 2005

ABSTRACT

Electrical oscillations in a metallic "sending coil" radiate inductive photons toward one or more "energy-magnifying coils" comprised of a photoconductor or doped semiconductor coating a metallic conductor, or comprised of a superconductor. Electrons of low inertial mass in the energy-magnifying coil(s) receive from the sending coil, a transverse force having no in-line backforce, which exempts this force from the energy-conservation rule. The low-mass electrons in the energy-magnifying coil(s) receive increased acceleration proportional to normal electron mass divided by the lesser mass. Secondarily radiated inductive-photon energy is magnified proportionally to the electrons' greater acceleration, squared, e.g., the inductive-energy-magnification factor of CdSe photoelectrons with 0.13 x normal electron mass is 59 times. Magnified inductive-photon energy from the energy-magnifying coil(s) induces oscillating electric energy in one or more metallic "output coil(s)". The electric energy output exceeds the energy input if more of the magnified photon induction energy is directed toward the output coil(s) than is directed as a counter force to the sending coil. After an external energy source initiates the oscillations, feedback from the generated surplus energy makes the device a self-sustaining generator of electric power for useful purposes.

CROSS REFERENCE TO RELATED APPLICATION

This application corresponds to, and claims the benefit under 35 U.S.C. 119(e), of U.S. provisional application No. 60/697,729, filed on 8th July 2005, incorporated herein by reference in its entirety.

FIELD

This disclosure introduces a technical field in which practical electrical energy is created in accordance with the overlooked exception to the energy-conservation rule that Herman von Helmholtz described in his 1847 doctrine on energy conservation: "If . . . bodies possess forces which depend upon time and velocity, or which act in directions other than lines which unite each pair of material points, . . . then combinations of such bodies are possible in which force may be either lost or gained as infinitum". A transverse inductive force qualifies for Helmholtz's ad infinitum rule, but this force is not sufficient of itself to cause a greater energy output than input when applied to electrons of normal mass due to their unique charge-to-mass ratio. However, the increased acceleration of conduction electrons of less-then-normal inertial mass, as occurs in photoconductors, doped semiconductors, and superconductors, is proportional to the normal electron mass divided by the low electron mass, and the magnification of harnessable inductive energy is proportional to the square of the greater relative acceleration.

BACKGROUND

Magnetic force also satisfies Helmholtz's exemption to the energy-conservation rule because magnetic force is transverse to the force that causes it, and magnetic force is determined by the "relative velocity" (i.e. perpendicular to the connecting line) between electric charges. Magnification of magnetic force and energy was demonstrated by E. Leimer (1915) in the coil of a speaker phone and in the coil of a galvanometer when he irradiated a radio antenna-wire with radium. A 10 milligram, linear radium source produced a measured 2.6 fold increase in electrical current in the antenna wire in comparing inaudible radio reception without radium to audible reception with radium. This represented a $(2.6)^2 = 7$ times increase in electrical energy flowing through the respective wire coils. The possibility of this enhanced reception being attributed to a person's body holding the unit of radium to the wire was eliminated by Leimer's additional observation that whenever the orientation of the small radium unit was changed to approximately 30 degrees relative to the wire, the energy enhancement ceased.

Applicant has deduced that Leimer's energy magnification was most likely due to low-mass electrons that were liberated and made conductive in the antenna by alpha radiation, which allowed these special electrons to be given a greater than normal acceleration by the received radio broadcast photons. Applicant has further deduced that such low-mass electrons must have originated in a thin-film coating of cupric oxide (CuO) on the antenna wire. CuO is a dull black polycrystalline semiconducting compound that develops in situ on copper and bronze wire in the course of annealing the wire in the presence of air. Such CuO coatings have been observed by Applicant on historical laboratory wire at the Science Museum at oxford University, U.K. and on copper house wire of that era in the U.S., indicating that CuO coatings were commonplace. In later years, annealing has taken place under conditions that prevent most oxidation. This is followed by acid treatment to remove any remaining oxides, leaving shiny wire.

The same year that the English translation of Leimer's paper appeared in *Scientific American*, 16-year old Alfred M. Hubbard of Seattle, Washington, reportedly invented a fuelless generator, which he later admitted, employed radium. Applicant interprets this as implying that Leimer's energy-magnification was utilised by Hubbard with feedback to make it self-sustaining. Three years later, Hubbard publicly demonstrated a relatively advanced fuelless generator that illuminated a 20-watt incandescent bulb (Anon. 1919a). A reputable physics professor from Seattle College, who was intimately familiar with Hubbard's device (but not at liberty to disclose its construction details), vouched for the integrity of the fuelless generator and declared that it was not a storage device, but he did not know why it worked (Anon. 1919b). Because Hubbard initially had no financial means of his own, it is likely that the professor had provided Hubbard with the use of the expensive radium initially and thereby witnessed the inventing process in his own laboratory.

Newspaper photos (Anon. 1920a) of a more impressive demonstration of Hubbard's fuelless generator, show a device described as 14 inches (36 cm) long and 11 inches (28 cm) in diameter, connected by four heavy electrical cables to a 35 horsepower (26 kW) electric motor. The motor reportedly propelled an 18-foot open launch around a like at a speed of 8 to 10 knots (Anon. 1920b). The event was witnessed by a cautious news reporter who claims to have checked thoroughly for any wires that might have been connected to hidden batteries, by lifting the device and motor from the boat. Radioactive-decay energy can be eliminated as the main power source because about 10^8 times more radium than the entire world's supply would have been needed to equal Hubbard's reported electric energy output of 330 amperes and 124 volts.

Lester J. Hendershott of Pittsburgh, Pa., reportedly demonstrated a fuelless generator in 1928 that was claimed by Hubbard to be a copy of his own device (1928h). The president of Stout Air services, William B. Stout, who also designed the Ford Trimotor aeroplane, reported (1928b): "The demonstration was very impressive. It was actually uncanny.... The small model appeared to operate exactly as Hendershot explained it did". Also reportedly attesting to the operability of Hendershott's fuelless generator were Colonel Charles A. Lindbergh and Major Thomas Lanphier of the U.S. Air Corps (1928a, et seq.), and Lanphier's troops reportedly assembled a working model of his device.

To the Applicant's best knowledge, the only depiction that was made public of the interior components of any of these reported generators consists of a sketchy drawing (Bermann 1928h) of Hubbard's apparatus similar in size to the device shown in his 1919 demonstration. It depicts a complex set of parallel coils measuring 6 inches (15 cm) in length and 4.5 inches (11.4 cm) in overall diameter. Four leads of insulated wire, with the insulation peeled back, are shown coming out of the end of the device. What those four wires were connected to internally was not shown. Hubbard's description of the internal arrangement of coils in the device generally matches the drawing (Anon. 1920a): "It is made up of a group of eight electromagnets, each with primary and secondary windings of copper wire, which are arranged around a large steel core. The core likewise has a single winding. About the entire group of cells is a secondary winding". Nothing was reported or depicted about how components functioned with each other, or how much radium was used and where the radium was positioned. The only connectors visible on the drawing were between the outer windings of the eight electromagnet coils. These connectors show that the direction of the windings alternated between clockwise and counterclockwise on adjacent coils, so that the polarity of each electromagnet would have been opposite to that of it's adjacent neighbours.

If the Hubbard and Hendershot devices actually operated as reported, they apparently never attained acceptance or commercial success. Assuming the devices actually worked, their lack of success may have been largely financially or supply based, or both, compounded with scepticism from believers in the energy-conservation doctrine. How much radium was employed by Hubbard in his larger generator can only be guessed at, but assuming a typical laboratory radium needle containing 10 milligrams of radium was used, that amount would have cost $900 in 1920, dropping to $500 in 1929. That much radium in a fuelless generator would have cost as much as an inexpensive automobile in the 1920s. Possibly much more radium was used than 10 milligrams.

In 1922, when the Radium Company of America of Pittsburgh, Pa., reportedly discontinued its work with Hubbard on his invention (1928h), the entire world's supply of radium was only about 250 grams. With the extreme assumption that only 1 milligram of radium was needed per generator, less than 10% of a single year's production of autos in the US in the mid-1920s could have been supplied with such generators. Apparently Hendershott had tried to revive the technology by showing that the fuelless generator could extend the range of air flight indefinitely, but his technology never attracted a sponsor from any private, public or philanthropic entity.

U.S. Pat. No. 4,835,433 to Brown, superficially resembles the drawing of Hubbard's device. Brown's device appears to have the same number and essentially the same general arrangement of wire coils as Hubbard's generator, as nearly as can be understood from the newspaper articles depicting that device. Apparently, no information concerning either the Hubbard or Hendershot devices was considered during the prosecution of the '433 patent. Brown discusses the conversion of energy of radioactive decay products, principally alpha emissions, to electrical energy by amplifying electrical oscillations in a high-Q L-C circuit irradiated by radioactive materials. "During the absorption process, each alpha particle will collide with one or more atoms in the conductor, knocking electrons from their orbits and imparting some kinetic energy to the electrons in the conductor, thereby increasing its conductivity". (Col. 3, Line 68 to Col. 4, line 5). No claim was made by Brown, that the device employed a semiconductor or photoconductor that could have provided low-mass electrons for energy magnification.

Brown claimed an output of 23 amps at 400 volts, which is vastly greater than all the decay energy represented by his reported radioactive content of 1 milligram of radium that was surrounded by weakly radioactive uranium rods and thorium powder. Powered thorium is highly pyrophoric, so it is typically sealed in a nitrogen atmosphere to prevent spontaneous combustion. In his device, Brown reportedly confined the thorium in cardboard without any mention of sealing out air. This condition would have invited a meltdown that could have been interpreted as massive out-of-control electrical production.

To the best of the Applicant's knowledge, no person other than the Applicant has ever indicated that the presence of cupric oxide on their wires could have provided energy magnification. If Hubbard's device actually did work, certain characteristics of its design are unexplainable by the Applicant, namely the use of four rather than two large electrical cables to connect his device to an electrical motor, and the use of alternating polarity instead of single-direction polarity in the orientation of the multiple coils surrounding a central coil. Applicant therefore believes that the specification herein sets forth original configurations of electrical-energy generators that have no known precedent.

SUMMARY

To address the needs for electrical generators which are capable of self-generating substantial amounts of electrical power in various environments, and which are portable as well as stationary, apparatus and methods are provided for magnifying an electrical input, and (with feedback) for generating usable electrical power indefinitely without fuel or other external energy source, except for starting. The apparatus utilises electrons of low effective mass, which receive greater acceleration than normal electrons in an amount that is inversely proportional to the effective mass. Applicant has determined that effective mass is the same as the electron's true inertial mass. The photon energy that is radiated when an electron is accelerated is proportional to the square of the acceleration, so the increase in radiated photon energy from an accelerated low-mass electron over the energy from a normal electron is equal to the inverse square of the effective mass, e.g. the calculated energy magnification provided by photoconducting electrons in cadmium selenide, with an electron effective mass of 0.13, is 59 times. The use of a transverse force, that lacks a direct back-force, to accelerate low-mass electrons in an oscillating manner, circumvents any equal-and-opposite force that would invoke the application of the energy-conservation law of kinetics and thermodynamics.

The various embodiments of the apparatus, which are configured either to continuously magnify an input of oscillating electric energy, or to serve as a self-sustaining electric generator, employ three principal components:

At least one sending coil

At least one energy-magnification coil, comprising a material that produces , in a "condition" low-mass electrons, and

At least one output coil.

It is desirable that the apparatus also includes a means for establishing the condition with respect to the energy-magnifying coil(s). Except where otherwise indicated in the remainder of this text, where the number of coils of a particular type is referred to in the singular, it will be understood that a plurality of coils of the respective type can alternatively be utilised.

Electrical oscillation in the sending coil, which is comprised of a metallic conductor, causes radiation of inductive photons from the sending coil. The energy-magnifying coil is situated in a position relative to the sending coil so as to receive inductive photons from the sending coil. The inductive photons radiating from electrical oscillations in the sending coil, convey a transverse force to the low-mass electrons in the energy-magnification coil with no back-force on the sending coil. The greater-than-normal accelerations which are produced in the low-mass electrons of the energy-magnifying coil, produce greater irradiation energy of inductive photons than normal.

The output coil is positioned so as to receive the magnified inductive-photon energy from the energy-magnifying coil. The inductive-photon energy received by the output coil, which is comprised of a metallic conductor, is converted into an oscillating electrical current of normal electrons. In order for the electrical output to exceed the electrical input, the output coil is situated in such a manner that it receives more of the magnified inductive-photon energy than that which is directed back against the sending coil to act as a back-force. This “energy leverage” causes the electrical energy output to exceed the electrical energy input.

By way of example, the energy-magnifying coil can comprise a superconducting material, wherein the “condition” is a temperature (e.g. a cryogenic temperature) at which the superconducting material exhibits superconducting behaviour characterised by production of low-mass electrons.

By way of another example, the energy-magnifying coil can comprise a photoconductive material, wherein the “condition” is a situation in which the photoconductive material is illuminated by a wavelength of photon radiation sufficient to cause the photoconductive material of the energy-magnifying coil to produce conduction electrons having low effective mass. In this latter example, the means for establishing the condition can comprise a photoconductor exciter (e.g. one or more LEDs) situated and configured to illuminate the photoconductive material of the energy-magnifying coil with the wavelength of photon radiation.

By way of yet another example, the “condition” is the presence of a particular dopant in a semiconductor that provides a low-mass electron as a charge carrier. Also, by way of example, the energy-magnifying coil can comprise a semiconductive element or compound that has been doped with a particular element or compound that makes it conductive of low-mass electrons without illumination by photon radiation other than by ambient photons.

Various apparatus embodiments comprise different respective numbers and arrangements of the principal components. The various embodiments additionally can comprise one or more of circuitry, energisers, shielding and other components to fulfill the object of providing a self-sustaining source of electrical power for useful purposes.

Also provided, are methods for generating an electrical current. In an embodiment of such a method, a first coil is energised with an electrical oscillation sufficient to cause the first coil to radiate inductive photons. At least some of the radiated inductive photons from the first coil are received by a second coil, called “the energy-magnifying coil”, comprising a material that produces low-mass electrons. The received inductive photons impart respective transverse forces to the low-mass electrons that cause the low-mass electrons to experience accelerations in the material which are greater than accelerations that otherwise would be experienced by normal free electrons experiencing the transverse forces.

Conduction of the accelerated low-mass electrons in the second coil, causes the second coil to produce a magnified inductive force. The magnified inductive force is received by a third coil which causes the third coil to produce an oscillating electrical output of normal conduction electrons which has greater energy than the initial oscillation. A portion of the oscillating electrical output is directed as feed-back from the third coil to the sending coil, so as to provide the electrical oscillation to the sending coil. This portion of the oscillating electrical current directed to the sending coil, desirably is sufficient to cause self-sustaining generation of inductive photons by the first coil without the need for any external energy source. The surplus oscillating electrical output from the third coil can be directed to a work loop.

The method can further comprise the step of starting the energisation of the first coil to commence generation of the oscillating electrical output. This “starting” step can comprise momentarily exposing the first coil to an external oscillating inductive force or for example, to an external magnetic force which initiates an electrical pulse.

The foregoing and additional features and advantages of the invention will be more readily apparent from the following detailed description, which proceeds with reference to the accompanying drawings.

DETAILED DESCRIPTION

General Technical Considerations

An understanding of how "infinite energy" mistakenly came to be rejected by the scientific community, clarifies the basis of this invention. The electrodynamic function described in the embodiments described below, conforms to Helmholtz's alternate energy rule, which states that a force which is not in line with it's causative force "may be lost or gained ad infinitum". This rule was included in "Uber die Erhaltung der Kraft" ("On the Conservation of Force") that Hermann Helmholtz delivered to the Physical Society of Berlin in 1847. But, Helmholtz mistakenly believed that "all actions in nature are reducible to forces of attraction and repulsion, the intensity of the forces depending solely upon the distances between the points involved .... so it is impossible to obtain an unlimited amount of force capable of doing work as the result of any combination whatsoever of natural objects".

Helmholtz refused to accept the idea that magnetic energy qualifies for ad infinitum status despite the fact that Ampere's (1820) magnetic force on parallel straight conductors is obviously transverse to the direction of the electric currents rather than being in line with the currents. He omitted mention that the magnetic force in Ampere's (1825) important invention, the solenoidal electromagnet, is caused by currents in the loops of his coils, which are transverse to the direction of magnetic force. Also, he failed to mention that Ampere considered the magnetic force of a permanent magnet to be caused by minute transverse circular currents, which are now recognised as electrons that spin and orbit transversely.

Helmholtz, who was educated as a military medical doctor without any formal study of physics, relied instead on an obsolete metaphysical explanation of magnetic force: "Magnetic attraction may be deduced completely from the assumption of two fluids which attract or repel in the inverse ratio of the square of their distance....It is known that the external effects of a magnet can always be represented by a certain distribution of the magnetic fluids on its surface". Without departing from this belief in magnetic fluids, Helmholtz cited Wilhelm Weber's (1846) similarly wrong interpretation that magnetic and inductive forces are directed in the same line as that between the moving electric charges which cause the forces.

Weber had thought that he could unify Coulombic, magnetic, and inductive forces in a single, simple equation, but Weber's flawed magnetic-force term leads to the absurd conclusion that a steady current in a straight wire induces a steady electric current in a parallel wire. Also, a changing current does not induce an electromotive force in line with the current, as Weber's equation showed. The induced force is offset instead, which becomes more apparent the further that two nested, coaxial coils are separated. What appears to be a directly opposing back-force is actually a reciprocal inductive force.

Helmholtz's assertion that the total sum of the energy in the universe is a fixed amount that is immutable in quantity from eternity to eternity appealed to his young friends. But, the elder scientists of the Physical Society of Berlin declared his paper to be "fantastical speculation" and a "hazardous leap into very speculative metaphysics", so it was rejected for publication in Annalen der Physik. Rather than accept this rejection constructively, Helmholtz found a printer willing to help him self-publish his work. Helmholtz headed the publication with a statement that his paper had been read before the Society, but he disingenuously withheld mention of its outright rejection. Unwary readers have since received the wrong impression that his universal energy-conservation rule had received the Society's endorsement rather than its censure.

Helmholtz (1862, 1863) publicised his concept thus: "We have been led up to a universal natural law, which ... expresses a perfectly general and particularly characteristic property of all natural forces, and which ... is to be placed by the side of the laws of the unalterability of mass and the unalterability of the chemical elements". Helmholtz (1881) declared that any force that did not conserve energy would be "in contradiction to Newton's axiom, which established the equality of action and reaction for all natural forces" (sic). With this deceitful misrepresentation of Newton's strictly mechanical principle, Helmholtz had craftily succeeded in commuting the profound respect for Newton's laws to his unscientific doctrine. Subsequently, the Grand Cross was conferred on Helmholtz by the kings of Sweden and Italy and the President of the French Republic, and he was welcomed by the German Emperor into nobility with the title of "von" added to his name. These prestigious awards made his doctrine virtually unassailable in the scientific community.

Ampere's principle of transverse magnetic attraction and repulsion between electric currents had been made into an equation for the magnetic force between moving electric charges by Carl Fredrick Gauss (written in 1835, published posthumously in 1865). The critical part of the Gauss equation shows, and modern physics texts agree, that magnetic force is transverse to the force that imparts a relative velocity (i.e. perpendicular to a connecting line) between charges. Lacking a direct back-force, a transverse magnetic force can produce a greater force than the force that causes it.

The only physicist to recognise in print, the profound significance of the work of Gauss, was James Clerk Maxwell (1873), who stated "(If Gauss's formula is correct), energy might be generated indefinitely in a finite system by physical means". Prepossessed with Helmholtz's "law", Maxwell chose not to believe Gauss's transverse magnetic-force equation and accepted Wilhelm Weber's (1846) erroneous in-line formula instead. Maxwell even admitted knowing of Gauss's (1845) rebuke of Weber for his mistaken direction of magnetic force as "a complete overthrow of Ampere's fundamental formula and the adoption of essential a different one".

In 1893, the critical part of Ampere's formula for magnetic force, which Weber and Maxwell rejected, and which Helmholtz had replaced with his contrary metaphysical explanation, was proposed for the basis for the international measure of electric current, the Ampere (or amp), to be defined in terms of the transverse magnetic force which the current produces. But Helmholtz's doctrine had become so impervious to facts that anyone who challenged this "law" faced defamation and ridicule.

The first recognition of unlimited energy came from Sir Joseph Larmor who reported in 1897, "A single ion e, describing an elliptic orbit under an attraction to a fixed centre ... must rapidly lose its energy by radiation ... but in the cases of steady motion, it is just this amount that is needed to maintain the permanency of motion in the aether". Apparently to mollify critics of his heretical concept, Larmor offered a half-hearted recantation in 1900: "The energy of orbital groups ... would be through time, sensibly dissipated by radiation, so that such groups could not be permanent".

In 1911, Rutherford found that an atom resembles a small solar system with negative ions moving like planets around a small, positively charged nucleus. These endlessly orbiting electrons were a source of the perpetual radiation that had aptly been described by Larmor, and these orbiting electrons were also Planck's (1911) "harmonic oscillators" which he used to explain Zero-point Energy (ZPE). ZPE was shown by the fact that helium remains liquid under atmospheric pressure at absolute zero, so that helium must be pressurised to become solid at that temperature. Planck believed that harmonic oscillators derived "dark energy" from the aether to sustain their oscillations, thereby admitting that an infinite source of energy exists. However, he assigned an occult origin to this infinite energy, rather than a conventional source that had not met with Helmholtz's approval.

Niels Bohr (1924) was bothered by the notion that radiation from an orbiting electron would quickly drain its energy so that the electron should spiral into the nucleus. Whittaker (1951) states, "Bohr and associates abandoned the principle ... that an atom which is emitting or absorbing radiation must be losing or gaining energy. In its place, they introduced the notion or virtual radiation, which was propagated in ... waves but which does not transmit energy or momentum". Subsequently, the entire scientific community dismissed Larmor radiation as a source of real energy because it failed to conform to Helmholtz's universally accepted doctrine.

Helmholtz's constraining idea that the vast amount of light and heat radiating from the many billions of stars in the universe can only come from previously stored energy, has led scientists to concur that fusion of pre-existing hydrogen to helium, supplies nearly all the energy that causes light and heat to radiate from the sun and other starts. If so, then the entire universe will become completely dark after the present hydrogen supply in stars is consumed in about 20 billion years. William A. Fowler (1965) believed that essentially all the hydrogen in the universe "emerged from the first few minutes of the early high-temperature, high-density stage of the expanding Universe, the so-called 'big bang' ..." Moreover, the background energy of the universe was thought by some to be "relic" radiation from the "Big Bang".

To accept the Big Bang idea that all the stars in the universe originated at the same time, it was necessary to disregard the fact that most stars are much younger or much older than the supposed age of the one-time event, which indicates that their energy must have come from a recurring source. The Big Bang is entirely dependent on the idea that the whole universe is expanding, which stemmed from the interpretation that Hubble's red-shift with distance from the light source, represents a Doppler shift of receding stars and galaxies. This expanding-universe interpretation was shattered by William G. Tifft (1976, 1977), who found that observed red-shifts are not spread randomly and smoothly over a range of values, as would be expected from the Doppler shifts of a vast number of receding stars and galaxies. Instead, the observed red-shifts all fall on evenly spaced, quantised values.

Moreover, Shpenkov and Kreidik (2002) determined that the radiation temperature corresponding to the fundamental period of the orbital electron motion in the hydrogen atom of 2.7289^0K matches the measured temperature of cosmic background radiation of 2.725^0K plus or minus 0.002^0K. This represents perpetual zero-level Larmor radiation from interstellar hydrogen atoms dispersed in the universe. So, Helmholtz's idea that "the energy in the universe is a fixed amount immutable in quantity from eternity to eternity" does not stand up to known facts.

The large aggregate quantity of heat-photons which is generated continually by Larmor radiation can account for the illumination of stars and for the enormous heat and pressure in active galactic centres. Based on the fact that photons exhibit momentum, photons must posses mass, because, as Newton explained, momentum is mass times velocity, which in this case is "c". Consequently, the creation of photons by induction or by Larmor radiation, also creates new mass. The conditions that Fowler was seeking for hydrogen nucleosynthesis, are apparently being supplied indefinitely in active galaxies and possibly in the sun and other stars above a certain size. This invention utilises a similar unlimited energy source.

Another principle that is important to this specification, is that the transfer of energy by electrical induction was found by the Applicant to work in the same manner as the transfer of energy by broadcast and reception of oscillating radio signals. A transverse force is communicated in both cases, the force declines similarly with distance, and the effects of shielding and reflection are identical. Since radio signals are communicated by photons, Applicant considers that inductive force is also communicated by photons. The radiation of newly formed inductive photons results when an accelerated charge experiences a change in direction of acceleration. Inductive radiation occurs when the acceleration of electric charges is reversed, as in Rontgen's bremsstrahlung, in Hertz's linear oscillator (plus all other radio-broadcasting antennas), and in coils which carry an alternating current.

In a similar case, when electric charges move in a curving motion due to a continually changing centripetal acceleration, inductive photons are radiated steadily. This includes the radiation from electrons orbiting atomic nuclei (Larmor radiation) and from conduction electrons flowing in a wire coil, whether the current is steady or not. Circularly produced inductive photons induce a circular motion (diamagnetism) in mobile electrons located near the axis of the electron's circular movement.

In both the reverse-acceleration and centripetal-acceleration cases, inductive photons convey a force to mobile electrons that is transverse to the photon's propagation path. As Lapp and Andrews (1954) reported, "Low-energy photons produce photoelectrons at right angles to their path ...". This same right-angle force without a direct back-force, applies as well, to all conduction electrons which are accelerated by low-energy photons. Hence, inductive energy qualifies for exemption from the energy-conservation law by Helmholtz's same ad infinitum principle which exempts magnetic energy.

The transverse force that inductively produced photons delivered to mobile electrons, is opposite in direction to the simultaneous movement of the primary charge which produces the radiation. This is shown by Faraday's induced current opposite to the inducing current and by the diamagnetically-induced circular motion which, in a rotational sense, is opposite to the circular electron motion in the coil producing it. An oscillating flow of electrons within a loop of a wire coil, induces a force on the conduction electrons which is in the opposite direction in adjacent loops of the same wire. This results in self-induction.

Important to this specification is the realisation that the energy transmitted by photons is kinetic rather than electromagnetic. Inductively radiated photons of low energy, light rays and X-rays cannot be deflected by and electric or magnetic field due to the photons' neutral charge. Neither do neutral photons carry an electric or magnetic field with them. Photon radiation is produced by a change in the acceleration of an electric charge, so only in special cases does it have an electrokinetic origin which involves a magnetic force. To honour these facts, Applicant uses the term "electrokinetic spectrum" in place of "electromagnetic spectrum".

Another principle which is important to this specification is the realisation that, although the charge on the electron has a constant value under all conditions, the mass of an electron is not a fixed, unchanging amount. All free electrons, as in cathode rays, have exactly the same amount of mass at sub-relativistic velocities. This is called "normal" mass and is denoted by m_e. Free electrons have a unique charge to mass ratio that makes the magnetic force resulting from a sub-relativistic velocity imparted to such an electron, exactly equal to the energy input with "normal" electrons.

Also, when a normal electron is given a sub-relativistic acceleration, the inductive force it produces is equal to the force it receives. The mass of highly conductive electrons of metals is apparently very close to normal, but any very slight inductive-energy gains would be masked by inefficiencies. The ubiquity of free electrons and the conduction electrons of metals has led to the view that electron mass is a never-varying figure that would allow the energy conservation law to apply to magnetic energy and inductive energy.

Accurate determinations of electron mass in solid materials have been made possible by cyclotron resonance, which is also called diamagnetic resonance. The diamagnetic force produced by the steady flow of electrons in a wire coil, induces the mobile electrons of a semiconductor to move in a circular orbit of indefinite radius but at a definite angular frequency. This frequency is only related to the inductive force and the mass of the electron. At the same time, a repulsive magnetic force is developed by the relative velocity between the electron flow in the coil and the conduction electrons, causing the mobile electrons of the semiconductor to move in a helical path away from the coil rather than in planar circles. Only two measurements are needed to determine the mass of such an electron: the cyclotron frequency which resonates with the frequency of the electron's circular motion, and the strength of the inductive force, which is determined by the current and dimensions of the coil. Since the co-produced magnetic field is related to the same parameters, its measurement serves as a surrogate for inductive force.

Because the measured mass of conduction electrons in semiconductors is less than normal, a complicated explanation has been adopted to defend the constancy of electron mass in order to support Helmholtz's energy doctrine. An extra force is supposedly received from the vibrational lattice-wave energy of the crystal (in what would have to be an act of self-refrigeration) to make normal-mass electrons move faster than expected around a circular path, thereby giving the appearance that the electron has less mass than normal. In this explanation, the electron is considered to be a smeared-out wave rather than a particle, which is contradicted by the billiard-ball-like recoil of an electron when it is bumped by a quantum of radiation, as described by Arthur Crompton and Samuel Allison (1935).

The fallacy that borrowed energy can provide a boost in velocity to an electron, is more apparent in the case of linear motion. The effective-mass theory considers that the greater linear velocity is caused by a boost given to normal-mass electrons by a "longitudinal wave" imparted by an externally applied force in the same direction as the electron motion. Since this longitudinal wave is also considered to have a source in crystal-lattice vibrations, the effective-mass theory relies on a reversal of entropy in violation of the second Law of Thermodynamics.

No reasonable contribution of direct directional energy can be invoked from any source to impart abnormally great velocity to the conduction electrons in semiconductors. So, the operation of apparatus embodiments described herein, relies on electrons having particle properties and on electrons having less-then-normal inertial mass without invoking any special forces. This is supported by Brennan's (1999) statement that "the complicated problem of an electron moving within a crystal under the interaction of a periodic but complicated potential, can be reduced to that of a simple free particle, but with a modified mass". The term "effective" is herein considered redundant in referring to truly inertial mass, but "effective mass" still has relevance in referring to the net movement of orbital vacancies or "holes" in the opposite direction of low-mass electrons.

By F = ma, a low-mass electron receives greater acceleration and greater velocity from a given force than an electron of normal mass. The velocity and kinetic energy imparted to an electrically charged body by a force, are determined by the electric charge without regard to the body's mass. Having a smaller amount of mass, allows a body to attain a greater velocity with any given force. Hence, the magnetic force produced by the charge at this higher velocity will be greater than it would normally be for that same amount of force. This allows low-mass electrons to produce a magnetic force that is greater than the applied force.

Also, the amount of inductive radiation energy from accelerated electrons is related to an electron's charge without regard to its mass. The energy of inductive radiation increases with the square of the electron's acceleration according to Larmor's (1900) equation, while the acceleration is inversely proportional to the lesser electron mass relative to normal electron mass. Therefore, the greater-than-normal acceleration of low-mass electrons, allows the re-radiation of magnified inductive-photon energy at a magnification factor which is proportional to the inverse square of the electron's mass, e.g., the inductive-energy magnification factor of cadmium selenide photoelectrons with 0.13 of the normal electron mass is $(0.13)^2$ which is 59 times.

Electrons appear to acquire or shed mass from photons in order to fit the constraints of particular orbits around nuclei, because each orbit dictates a very specific electron mass. In metals, where the conduction electrons seem to move as would a gas, one might think that they would assume the normal mass of free electrons. But the largest mean free path of electrons in the most conductive metals is reportedly about 100 atomic spacings between collisions (Pops, 1997), so the conduction electrons apparently fall back into orbit from time to time and thereby regain their metal-specific mass values.

As conduction electrons pass from one metal type to another, they either lose or gain heat-photons to adjust their mass to different orbital constraints. In a circuit comprising two different metallic conductors placed in series contact with each other, the flow of conduction electrons in one direction will cause the emission of heat-photons at the junction, while an electron flow in the reverse direction causes cooling as the result of ambient heat-photons being absorbed by the conduction electrons at the junction (Peltier cooling effect). When a metal is joined with a semiconductor whose conductive electrons have much lower mass than in metals, much greater heating or cooling occurs at their junction.

John Bardeen (1941) reported that the (effective) mass of superconducting electrons in low-temperature superconductors is only 10^{-4} as great as the mass of normal electrons. This is demonstrated when superconducting electrons are accelerated to a much higher circular velocity than normal in diamagnetically induced eddy currents, which results in enormous magnetic forces which are capable of levitating heavy magnetic objects. Electrons with 10^{-4} times normal mass are apparently devoid, (or nearly devoid) of included photon mass, so normal electrons are deduced to posses about 10^{4} times more included photon mass than the bare electron's own mass.

The means by which photon mass may be incorporated within, or ejected from electrons, can be deduced from known information. Based on the Thompson scattering cross-section, the classical radius of a normal electron is 2×10^{-15} cm. If the electron has uniform charge throughout a sphere of that radius, the peripheral velocity would greatly exceed the velocity of light in order to provide the observed magnetic moment. Dehmelt (1989) determined that the radius of the spinning charge which creates an electron's magnetism, is approximately 10^{-20} cm. This apparent incongruity can be explained if the electron is considered to be a hollow shell (which is commensurate with the bare electron's tiny mass in comparison to the very large radius) and if the negative charge of the shell is not the source of the magnetic moment.

It has long been known that a photon can be split into an negative ion (electron) and a positive ion (positron), each having the same amount of charge but of opposite sign. Electrons and positrons can recombine into electrically neutral photons, so it is apparent that photons are composed of a positive and a negative ion. Two ions spinning around each other could produce the photon's wave nature. The only size of photon ion that can exist as a separate entity has a charge of exactly plus one or minus one, whereas the ions can have a very much larger or very much smaller charge and mass when combined in photons, as long as the two ions are equal in charge and mass. Combined in a photon, the two ions are apparently attracted together so strongly that their individual volumes are very much smaller than as separate entities.

When a dipole photon enters an electron shell, its negative-ion portion is expected to be forced towards the shell's centre by Coulombic repulsion, while the photon's positive ion would be attracted by the negative charge of the shell equally in all directions. The negative photon ions would likely merge into a single body at the electron's centre, while the positive-ion portion would orbit around the centralised negative ion to retain the photon's angular momentum. The high peripheral velocity of this orbiting photon mass would enable portions of photon material to spin off and exit the electron shell at the same velocity at which they entered the electron, i.e., the speed of light. The orbiting of the positive photon charge at Dehmelt's small radius, most likely accounts for the magnetic moment that is observed in electrons of normal mass.

Liberated low-mass conduction electrons within intrinsic semiconductors (which are also photoconductors by their nature) and within doped semiconductors, are mostly protected against acquiring mass from ambient-heat photons by the heat-insulative properties of the semiconductors. In contrast, low-mass electrons injected into heat-conducting metals, rapidly acquire mass from ambient-heat photons by the existence of cryogenic conditions, but they are vulnerable to internal heat-photons created by excessive induction.

Conduction electrons of metals, typically move as a group at drift velocities of less than one millimetre per second, although the velocity of the electrical effects approaches the velocity of light. (Photons are probably involved in the movement of electrical energy in metallic conductors.) In contrast, conductive low-mass electrons can move individually at great velocities in superconductors and semiconductors. Brennan (1999, p. 631) reports the drift velocity of a particular electron moving in a semiconductor, to be one micrometer in about 10 picoseconds, which is equivalent to 100 kilometers per second.

The concentration of the conduction electrons in metals is the same as the number of atoms, whereas in semiconductors, the mobile low-mass electrons which are free to move, can vary greatly with the amount of certain photon radiation received. Since the magnitude of an electric current is a summation of the number of electrons involved, times their respective drift velocities, the current developed by a small ensemble of photoconducting electrons moving at high speed, can exceed the current of a much greater number of conduction electrons moving at a very low speed in a metal.

A general feature of intrinsic semiconductors is that they become photoconductive in proportion to the amount of bombardment by some particular electron-liberating frequency (or band of frequencies) of photon energy, up to some limit. The amount of bombardment by the particular wavelength (or, equivalently, the frequency), increases along with all other photon wavelengths as the ambient temperature rises, that is, as the area under Planck's black-body radiation curve increases. Consequently, the conductivity of semiconductors continues to increase with temperature, while the conductivity drops to almost zero at low temperature unless superconductivity occurs.

A single high-energy alpha particle can liberate a great number of low-mass electrons in a thin-film semiconductor, as Leimer's (1915) energy-magnifying experiment appears to show. Leimer's alpha radiation was situated near the distant end of a suspended antenna wire of unreported length, when he experienced the maximum magnetic energy increase in the coil of the ammeter in the receiver. The low-mass electrons had to have travelled the entire length of the suspended antenna and the connecting line to his receiving apparatus without encountering any trapping holes. Assuming these electrons traversed a distance of 1 to 10 metres in less than one half-cycle of the radio frequency, (that is, less than 4 microseconds at 128 kHz) at which time the direction of the low-mass electron would have been reversed, this would be equivalent to velocities of 25 to 250 km/sec.

A great number of superconducting electrons can be set in motion by inductive photon radiation. In contrast, inductive photon radiation can pass mostly through photoconductors that have low concentrations of mobile, low-mass electrons. Applicant's interpretation of Leimer's experiment is that the liberated low-mass electrons of the semiconductor coating of the antenna wire, were not directly accelerated by the inductive photons of the radio signal, but rather were accelerated to high velocities by an oscillating electric field created in the metallic wire by the radio photons.

A review of an experiment performed by File and Mills (1963), shows that the very low mass of superconducting electrons is responsible for causing supercurrents to differ from normal electric currents. A superconducting solenoidal coil (comprising a Nb-25% Zr alloy wire below 4.3^0 K.) with the terminals spot-welded together to make a continuous conductor, was employed. Extremely slow declines of induced supercurrents were observed, which can be attributed to an enormous increase in the coil's self-induction. Because a supercurrent approaches its maximum charge asymptotically when discharging, a convenient measure of the coil's charging or discharging rate is the "time-constant". The time-constant has the same value for both charging and discharging, and it is defined as (a) the time needed for charging the coil to 63% of the maximum amount of current inducible in the coil by a given diamagnetic force, or (b) the time needed to discharge 63% of the coil's induced current.

In normal conductors, the inductive time-constant is calculated by the inductance of the coil, divided by the resistance of the coil. By use of an empirical equation, the inductance of the coil in its non-superconducting state is calculated to be 0,34 Henry, based on a double-layered solenoid of 384 turns that measured 4 inches (10 cm) diameter and 10 inches (25 cm) long. The resistance of the 0.020 inch (0.51 mm) diameter wire at a temperature of 5^0 K. (just above T_C) is estimated by using data for Zr alone, to be 4×10^2 ohms. (Resistivity data were not available for Nb or the subject alloy). Under non-superconducting conditions, the time-constant for charging and discharging this coil is thereby calculated to be approximately 8×10^{-5} sec.

The time it took to charge up a supercurrent in the coil in the experiment was not reported. But, based on the reported 50 re-energisings and magnetic determinations performed in 200 hours, the measured charging time in the superconducting state is computed to be no more than 4 hours on average.

Using Bardeen's (1941) formula of m is approximately equal to m_e times 10^{-4} for the order of magnitude of the low T_C superconducting electron's mass, and using Larmor's equation (1900) which relates inductive radiation power to the square of the acceleration of the charge, the inductance of the coil is expected to increase by $(10^4)^2 = 10^8$ times in the superconducting state. Thus, the calculated increase in the time-constant of charging up the supercurrent is $8 \times 10^{-5} \times 10^8$ which equals 8×10^3 seconds, or 2.2 hours, which is the same order of magnitude as the maximum actual charging time. The self-induction increased by that amount because the low-mass electrons are accelerated 10^4 times faster.

In the case of discharging, the time constant of the supercurrent was projected by File and Mills from measured declines observed over periods of 21 and 37 days. The projections of the two 63% declines agreed closely at 4×10^{12} seconds (= 1.3×10^5 years). Therefore, the time-constant of supercurrent discharge, based on projecting actual measurements, had increased by 5×10^{16} times over the time-constant for electrons of normal mass.

The driving force during charging, had been the applied inductive force, whereas the driving force during discharging was the supercurrent that had been magnified 10^8 times. Therefore, during the discharging of the supercurrent, the time-constant is increased again by 10^8 times, so the calculated total increase in the time-constant of discharge is $10^8 \times 10^8 = 10^{16}$ times greater than the normal time-constant. This calculated value of the non-superconducting time-constant, based solely on the increase of inductive radiation due to extremely low electron mass, compares favourably in magnitude with the actually observed value of 5×10^{16} times the normal time-constant.

The superconducting coil required no more than four hours to charge up the supercurrent, yet during subsequent discharge, the superconducting coil was projected to radiate inductive photon energy from the centripetal acceleration of the superconducting electrons for 130,000 years before declining by 63%. If this experiment could take place where no energy would needed to sustain critical cryogenic conditions, as in outer space, the lengthy discharge of this energised coil would clearly demonstrate the creation of energy in the form of newly-created photons inductively radiating from the superconducting low-mass electrons that circulate around the coil's loops. Applicant interprets this as showing that low-mass electrons are capable of inductive-energy-magnification based solely on their mass relative to that of normal electrons.

In the embodiments described below, the magnified inductive energy of low-mass electrons is utilised in coils for electric-energy generation by employing a flow of inductively accelerated photons that alternates in direction. This, in turn, drives low-mass electrons in an oscillating manner, so this forced reversal involves only a single stage of inductive-energy magnification, rather than the two stages (charging and naturally discharging) in the foregoing experiment.

Mode of Operation

Inductive photons radiating from an oscillating electric current in a sending conductor (e.g. from a radio-wave broadcasting antenna) convey a force, on conduction electrons in a receiving conductor, that is transverse to the incidence direction of the incident inductive photons on the receiving conductor. As a result, no back-force is transferred directly back to the sending conductor. Applicant has discovered that the action of this transverse force on low-mass electrons in a receiving conductor is analogous to the action of Gauss's transverse magnetic force on free electrons in a conductor, which is not subject to the kinetics law of conservation of energy. If the receiving conductor has low-mass conduction electrons, then this transverse force would impart greater acceleration to the low-mass electrons than that it would impart to normal free electrons. The resulting greater drift velocities of low-mass electrons than normal free electrons in the receiving conductor, would yield an increased magnitude of inductive force produced by the low-mass electrons in the receiving conductor and hence produce a magnification of the irradiation energy of inductive photons.

The direction of the transverse force imparted by the radiated inductive photons on conduction electrons in the receiving conductor is opposite to the direction of the corresponding electron flow in the sending conductor. This relationship is similar to the inductive force on electrons in the secondary coil of a transformer, which also is opposite to the direction of flow of electrons in the primary coil.

Various embodiments of Applicant's electrical generator employ inductive photons radiated from electrical oscillations in a "sending coil". Inductive photons are radiated from the sending coil toward and inductive-photon receiving coil, termed an "energy-magnifying coil", which comprises a photoconductive or superconductive material, or other suitable material as described below. The energy-magnifying coil is placed in a condition favourable for the production of low-mass electrons that participate in electrical conduction in the energy-magnifying coil. For example, if the energy-magnifying coil is made of photoconductive material, the coil is provided with a photoconduction exciter. Alternatively, if the energy-magnifying coil is made of a superconductive material, the coil is placed in an environment at a temperature (T) no greater than the critical temperature (T_C); i.e., $T < T_C$. In the former example, the photoconduction exciter can be a source of illumination which provides an appropriate wavelength of excitive electrokinetic radiation. If the energy-magnifying coil is comprised of a doped semiconductor, the condition that provides mobile low-mass electrons already exists.

In the energy-magnifying coil, the greater-than-normal acceleration of the low-mass electrons produces greater-than-normal inductive forces in the form of greater-than-normal radiation of inductive photons from the coil. The resulting increased inductive-photon energy from the photoconductor or superconductor is converted into useful electrical energy in an output coil inductively coupled to the energy-magnifying coil. The output coil can be made of insulated metallic wire. An exemplary output coil is situated coaxially with, and nested within, the energy-magnification coil. A coil of this type is termed herein, an "internal output coil".

The ability of the subject apparatus to produce more energy output than energy input, is based on the output coil receiving more of the magnified energy from the energy-magnifying coil than is returned as a back-force from the output coil to the energy-magnifying coil. This principle is termed herein "energy leverage".

The oscillations in the energy-magnifying coil are initiated by an external energy-input source that provides an initiating impulse of electron flow in the sending coil. For example, the external energy-input source can be an adjacent independent electromagnet or an adjacent permanent magnet moved rapidly relative to the sending coil. The initiating impulse starts an oscillation in the sending coil that stimulates radiation of inductive photons from the sending coil to the energy-magnifying coil. Energy from the external energy-input source is magnified by the apparatus so long as the energy-magnifying coil does not act as an independent oscillator at a different frequency. Independent oscillation is desirably avoided by connecting the ends or terminals of the energy-magnifying coil to each other in such a way that it results in one continuous coil, or a continuous multiple-coil system or systems, connected together in such a way that continuity exists for the conduction of low-mass electrons throughout the entire coil system. The energy-magnifying coil inductively creates more energy in the output coil than the energy of the initial impulse. The resulting magnified output of electrical energy produced by the apparatus is available for useful purposes in a work loop.

After initiation, the apparatus is made self-sustaining using a feed-back loop arranged in parallel with the work loop that includes the sending coil, and with a capacitor located in the feed-back loop to make it an L-C circuit, i.e., after start-up of the apparatus using the external energy-input source, the apparatus becomes self-resonating, which allows the external energy-input source to be decoupled from the apparatus without causing the apparatus to cease production of electrical energy.

During normal self-sustained operation, a portion of the output electrical energy is returned to the sending coil by the feed-back loop, thereby overcoming the need to use the external energy-input source for sustaining the oscillations in the sending coil. In other words, after startup, the external energy which was used by the sending coil to excite the photoconductive material or the superconducting material in the energy-magnifying coil is replaced by a portion of the output energy produced by the apparatus itself. The remainder of the output electrical energy is available in the work loop for useful purposes.

Initiating the generation of electrical energy by the apparatus, takes advantage of the fact that the inductive back-force sent from the output coil to the energy-magnifying coil (and hence ultimately, back to the sending coil), arrives at the sending coil one cycle behind the corresponding pulse that initiated the flow of electrons. This one-cycle lag of the back-force, as well as a corresponding one-cycle lag in the feed-back, enables small starting pulses produced in the sending coil to produce progressively greater electrical outputs each successive cycle. Consequently, assuming that the electrical load is not excessive during start-up, only a relatively few initiating cycles from the external energy-input source typically are needed for achieving production by the apparatus of an amount of output power sufficient to drive the load as well as providing sufficient energy feed-back to the sending coil in a sustained manner.

A half-cycle of the one-cycle lag occurs between an initial acceleration of electrons in the sending coil and a corresponding initial oscillation in the energy-magnifying coil. This half-cycle lag occurs because induction photons are not radiated from the initial acceleration of electrons in the sending coil, but rather are radiated when the electrons are reverse-accelerated. (Kramers, 1923, and Compton and Allison, 1935, p.106). As the newly formed photons are being radiated by the respective deceleration of electrons in the sending coil, even more new photons are simultaneously being formed by the new direction (i.e. reverse direction) of acceleration under oscillating conditions. Thus, the radiation of photons from electrons alternatingly accelerated in the opposite direction from the conveyed force, continues each half-cycle after the initial half-cycle.

Applicant also discovered that a half-cycle lag also occurs between the initial flow of electrons in the primary coil of a certain type of transformer, which is simply comprised of coils nested coaxially rather than being inductively coupled by an iron core, and the resulting electron flow induced in the secondary coil. When applied to this apparatus, these finding indicate that a second half-cycle lag occurs between the acceleration of low-mass electrons in the energy-magnifying coil and the corresponding electron flow induced in the output coil. The feed-back from the output coil boosts the electron flow in the sending coil one whole cycle after the initial pulse.

As discussed above, the energy-magnifying coil comprises either a photoconductor, a doped semiconductor or a superconductor as a source of, and as a conductor of, low-mass electrons. The general configuration of the coil is similar in either case. The coil including a photoconductor or doped semiconductor, has an operational advantage at normal temperatures, and the coil including a superconductor has an operational advantage at sub-critical temperatures ($T < T_C$), such as in outer space.

Representative Embodiments

Fig. 1(A)

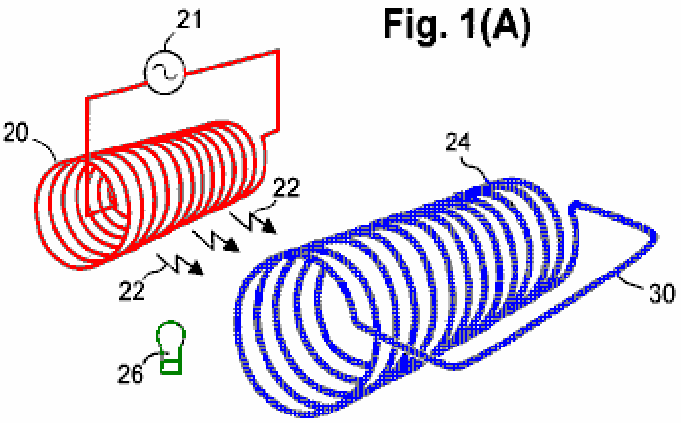

Fig. 1(B)

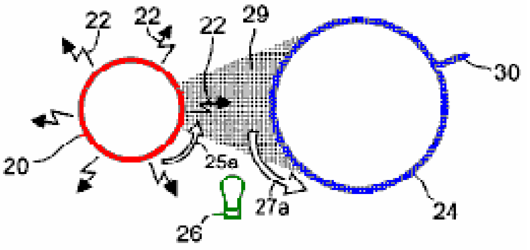

Fig. 1(C)

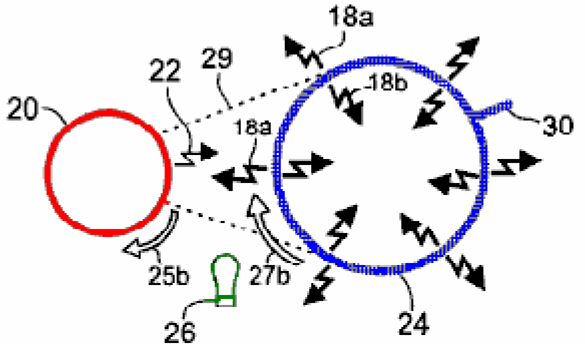


Reference is now made to **Fig.1A** to **Fig.1C** and **Fig.2A** and **Fig.2B** which depict a sending coil **20** connected to a source of alternating current **21**. The sending coil is shown having a desirable cylindrical profile, desirably with a circular cross-section as the most efficient configuration. In **Fig.1A** and **Fig.1B**, electrical oscillations from the source **21** are conducted to the sending coil **20** where they cause inductive photons **22** to radiate from the sending coil. The radiated photons **22** convey transverse forces in the same manner that a radio-broadcasting antenna transmits oscillating energy. The sending coil **20** can be a single layer or multiple layers of insulated metal wire (e.g. insulated copper wire). One layer is sufficient, but an additional layer or layers may increase operational efficiency. If necessary, or desired, the turns of wire can be formed on a cylindrical substrate made of a suitable dielectric.

The inductive photons **22** radiating from the sending coil **20**, propagate to an energy-magnifying coil **24** that desirably has a cylindrical profile extending parallel to the sending coil. In the embodiment shown in **Fig.1A** and **Fig.1B**, the energy-magnifying coil **24** does not terminate at the ends, but rather, it is constructed with a connector **30** to form a continuous conductor. The energy-magnifying coil **24** desirably is a helical coil made of a material comprising a photoconductive or superconductive material, or other suitable material. If necessary or desired, the energy-magnifying coil can be formed on a substrate which, if used, desirably is transmissive to the inductive-photon radiation produced by the coil.

In an energy-magnifying coil **24** made of a superconducting material, a large population of conductive low-mass electrons is produced in the coil by lowering the temperature of the coil to a point below the critical temperature for that material. By way of an example, sub-critical temperatures are readily available in outer space or are produced under cryogenic conditions.

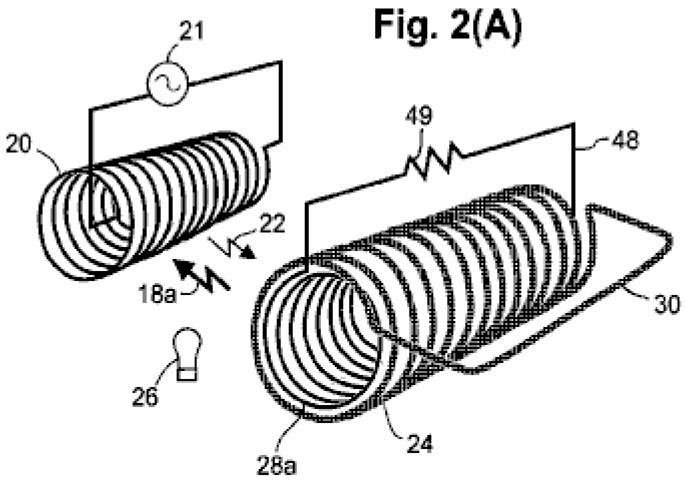
In an energy-magnifying coil **24** made of a photoconductor material, a large population of conductive low-mass electrons is produced in the coil by illuminating the coil with photons of an appropriate wavelength, such as photons produced by a photoconduction exciter **26**. The photoconductor exciter **26** desirably is situated and configured so as to illuminate substantially at least the same side of the energy-magnifying coil **24** that receives inductive photons **22** radiating directly from the sending coil **20**. Alternatively, the photoconduction exciter **26** can be situated and configured so as to illuminate all sides of the energy-magnifying coil **24**. In the depicted embodiment, the photoconduction exciter **26** can be at least one incandescent lamp (as shown) energised by conventional circuitry (not shown). Alternatively, the photoconduction exciter **26** can be at least one gas-discharge lamp or one or more Light Emitting Diodes. The wavelength produced by the photoconduction exciter **26** can be, for example, in the infrared (IR), visible, ultraviolet (UV), or X-ray range as required by the particular photoconductor material in the energy-magnifying coil **24**. Another possible form of the photoconduction exciter **26**, is a source of photons in the gigahertz or the terahertz portion of the electrokinetic spectrum. Other photoconduction exciters are configured, as required, to produce a suitable wavelength from the radio-wave portion of the electrokinetic spectrum. The illumination can be either direct from the photoconduction exciter **26** to the energy-magnifying coil **24** or conveyed from a remotely located photoconduction exciter to the energy-magnifying coil via optical fibres, light pipes, or the like.

Fig.1B and **Fig.1C** are respective orthogonal end views of the sending coil **20** and energy-magnifying coil **24** shown in **Fig.1A**. The radiation of inductive photons **22** from the sending coil **20**, is indicated schematically in **Fig.1A**, **Fig.1B** and **Fig.1C** by small, jagged arrows. The forces delivered by the photons **22** to the conductive low-mass electrons in the energy-magnifying coil **24**, alternate in directions which are opposite to the respective directions of simultaneous electron flow in the sending coil **20**. Whenever the particular oscillation phase of electron flow in the sending coil **20** is in the direction of the curved arrow **25a** adjacent to the sending coil **20** in **Fig.1B**, the resulting transverse photon force causes a flow of low-mass electrons in the energy-magnifying coil **24**, depicted by the curved arrow **27a** adjacent to the energy-magnifying coil **24**.

The shaded sector **29**, shown in **Fig.1B**, denotes the proportion of inductive-photon radiation **22** from the sending coil **20**, actually received by the single energy-magnifying coil **24** shown, compared to the entire 360-degree radiation of inductive photons **22** from the sending coil **20**. Aside from a small amount of inductive-photon radiation lost from the ends of the sending coil **20**, the relative amount of the total energy of inductive-photon radiation received by the energy-magnifying coil **24** is determined by the angle subtended by the energy-magnifying coil **24**, relative to the entire 360 degrees of inductive-photon radiation from the sending coil **20**.

In **Fig.1C**, the low-mass conduction electrons of the energy-magnifying coil **24** are accelerated to a higher drift velocity than normal free electrons in the energy-magnifying coil **24** would be. As noted above, the sending coil **20** is energised by alternating electron flow, which causes a periodic reversal of direction of electron flow in the sending coil **20** (compare the direction of the arrow **25b** in **Fig.1C** with the direction of the arrow **25a** in **Fig.1B**). Each reversal of direction of electron flow in the sending coil **20**, causes a corresponding reversal in the direction of acceleration of the low-mass electrons in the energy-magnifying coil **24** (compare the direction of the arrow **27b** in **Fig.1C** with the direction of arrow **27a** in **Fig.1B**). Each such reversal in direction of acceleration causes a corresponding radiation of inductive photons (jagged arrows **18a**, **18b**) radially outwards and radially inwards, respectively, from the energy-magnifying coil **24**. Note that the arrows **18a** and **18b** are larger than the arrows denoting the inductive photons (arrows **22**) from the sending coil **20**. This symbolically denotes energy magnification. Note also that, of the magnified inductive-photon energy radiating from the energy-magnifying coil **24**, substantially half is directed inwards (arrows **18b**), and substantially the other half is radiated outwards (arrows **18a**).

Fig. 2(A)



Turning now to **Fig.2A**, the sending coil **20**, and the energy-magnifying coil **24**, are shown. The energy-magnifying coil **24** in **Fig.2A** includes an internal output coil **28a**, that desirably is situated co-axially inside and is of the same length as the energy-magnifying coil **24**. A work loop **48** can be connected to the ends of the internal output coil **28a**, thereby forming an electrical circuit in which a load **49** is indicated symbolically as a resistor. The internal output coil **28a** and the conductors of the work loop **48**, desirably are made of insulated metallic (e.g. copper) wire.

Fig. 2(B)

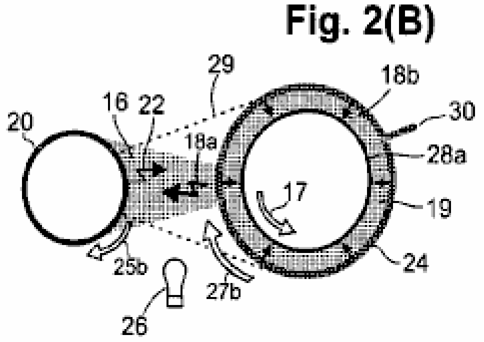


Fig.2B depicts a transverse section of the coils shown in **Fig.2A**. In **Fig.2B**, the magnified inductive-photon energy (shaded area **19**) produced by the energy-magnifying coil **24** and directed radially inwards towards the internal output coil **28a**, induces a corresponding oscillating electron flow in the internal output coil **28a**. Thus, the work loop **48** connected across the internal output coil **28a**, is provided with greater energy than was received by the energy-magnifying coil **24** from the sending coil **20**. The direction of the electron flow (arrow **17**) in the internal output coil **28a**, is opposite to the direction of flow (arrow **27b**) in the energy-magnifying coil **24**, which in turn is opposite to the direction of electron flow **25b** in the sending coil **20**.

In **Fig.2B**, the annular-shaped shaded area 19 between the energy-magnifying coil **24** and the internal output coil **28a**, indicates that substantially all of the internally-directed magnified inductive-photon energy (i.e. approximately half of the total radiation energy) from the energy-magnifying coil **24**, is directed to, and captured by, the internal output coil **28a**. In contrast, the shaded sector **16** extending from the energy-magnifying coil **24** to the sending coil **20**, indicates that a relatively small proportion of the outwardly directed magnified radiation **18a** from the energy-magnifying coil **24** is directed to the sending coil **20** where the radiation provides a corresponding back-force. Aside from the small amount of inductive-photon radiation lost from the ends of the energy-magnifying coil **24**, the relative amount of the magnified inductive-photon radiation (sector **16**) providing the back-force on the sending coil **20**, is a function of the angle subtended by the sector **16**, compared to the 360-degree radiation from the energy-magnifying coil **24**.

The ratio of magnified energy **18b** from the energy-magnifying coil **24** and received by the internal output coil **28a**, to the magnified energy **18a** received as a back-force by the sending coil **20**, denotes the energy “leverage” achieved by the subject apparatus. If this ratio is greater than unity, then the energy output from the internal output coil **28a** exceeds the energy input to the energy-magnifying coil **24**. This energy leverage is key to the self-sustained operation of the apparatus, especially whenever the apparatus is being used to drive a load. In other words, , with a sufficiently large energy-magnification factor achieved by the energy-magnifying coil **24**, the electrical energy available in the work loop **48**, exceeds the input energy that produces the oscillations in the sending coil **20**. The electric power input to the sending coil **20** thereby produces magnified electric power in the internal output coil **28a** that can perform useful work in the work loop **48** while self-powering the continued operation of the apparatus.

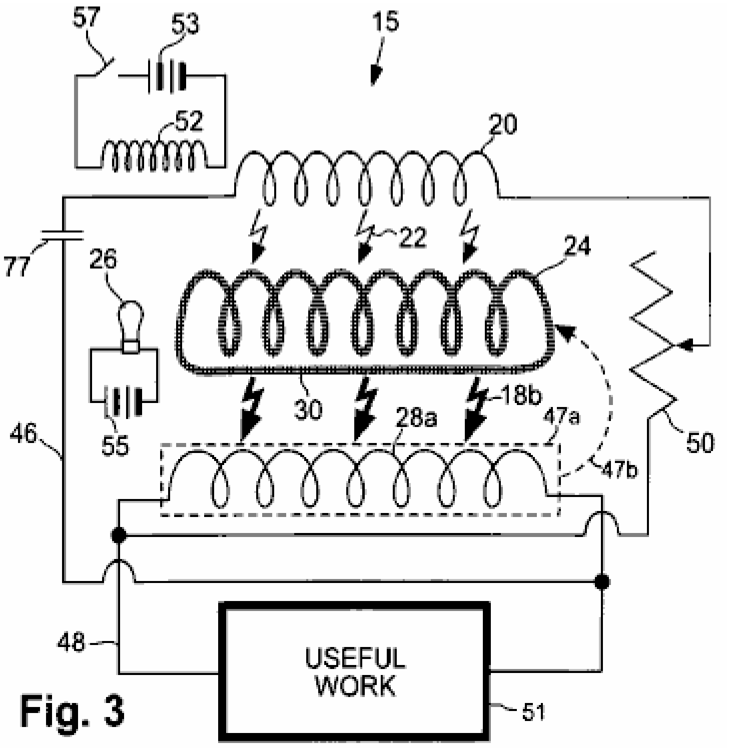

Fig. 3

Reference is now made to **Fig.3**, which schematically depicts aspects of the apparatus **15**, responsible for self-generation of electric power by employing a feed-back loop **46**. The conductors of the feed-back loop **46** can be made of insulated metallic wire. (In **Fig.3**, the dotted lines **47a** and dotted arrow **47b**, indicate that the internal output coil **28a** is actually positioned co-axially inside the energy-magnifying coil **24**, as described above, but is depicted in the figure as being outside the energy-magnifying coil for ease of illustration). The feed-back loop **46**, conducts a portion of the electric power from the internal output coil **28a**, back to the sending coil **20**. The remaining portion of the electric power from the internal output coil **28a** is directed to the work loop **48** where the power is utilised for useful work **51**. The relative proportions of output power delivered to the feed-back loop **46** and to the work loop **48**, can be varied by adjusting a variable resistor **50**.

As noted above, an initial source of electrical energy is used for “starting” the apparatus **15** by initiating an oscillation in the sending coil **20**. After starting, under usual operating conditions, the apparatus **15** is self-resonant and no longer requires the input of energy from the initial source. The particular inductance and distributed capacitance of the sending coil **20**, plus all other capacitances and inductances in the apparatus, provide a certain corresponding frequency of self-resonating oscillation. In the feed-back loop **46** is a capacitor **77** that makes the apparatus an L-C circuit which oscillates at its own frequency. the frequency can be changed by altering the capacitance or inductance of the apparatus, or both. the capacitor **77** can be a variable capacitor by which the frequency can be adjusted.

As shown in **Fig.3**, the initial source of oscillating electrical energy can be an impulse from an external electromagnet **52** powered by its own energy source (e.g. a battery **53** as shown, or other DC or AC source). For example, the electromagnet **52** can be placed near the sending coil **20** or other portion of the feed-back loop **46**, and energised by a momentary discharge delivered from the battery **53** via a switch **57**. The resulting pulse generated in the electromagnet **52**, initiates a corresponding electrical pulse in the sending coil **20** that initiates self-sustaining oscillations in the apparatus **15**. In another embodiment, the electromagnet **52** can be energised briefly by an AC source (not shown). In yet another embodiment, the initial source can be a permanent magnet which is moved rapidly (either mechanically or manually) near the sending coil **20** or other portion of the feed-back circuitry. In any event, the pulse provided by the initial source initiates electrical oscillations in the sending coil **20** that produce corresponding oscillating inductive-photon radiation **22** from the sending coil **20**, as shown schematically in **Fig.3** by thin jagged arrows. The inductive-photon radiation **22** from the sending coil **20** causes, in turn, re-radiation of magnified inductive-photon energy **18b** from low-mass electrons in the energy-magnifying coil **24**, as shown schematically in **Fig.3** by thick jagged arrows. **Fig.3** depicts a photoconductive energy-magnifying coil **24** which is illuminated by an incandescent photoconduction exciter **26** energised by its own power source **55** (e.g., an externally connected battery as shown).

A sufficiently high energy-magnification factor of the apparatus **15** allows the magnified energy from the energy-magnifying coil **24** to induce greater energy in the internal output coil **28a** than the energy of the corresponding initial pulse. A portion of the magnified electrical energy is returned to the sending coil **20** via the feed-back loop **46** to sustain the oscillations.

The remaining surplus energy from the internal output coil **28a** is available for application to useful work via the work loop **48**. In one embodiment, some of this useful work can be used for illuminating the photoconduction exciter **26** (circuitry not shown) in an apparatus configuration in which the energy-magnifying coil **24** comprises a photoconductor. In another embodiment, some of this useful work can be used for maintaining cryogenic ($T < T_c$) conditions for an apparatus configuration in which the energy-magnifying coil **24** comprises a semiconductor.

After starting oscillations in the apparatus **15**, electron flow builds up rapidly, so long as the load **49** does not draw off too much of the output energy during start-up. Upon reaching operating equilibrium, the output of electrical power from the apparatus **15** is a rapidly alternating current (AC). The AC output can be rectified by conventional means to produce direct current (DC), and the output can be regulated as required, using conventional means. Many variations of conventional circuitry are possible, such as, but not limited to, automatic voltage controllers, current controllers, solenoidal switches, transformers, and rectifiers,

Regarding the energy-magnifying coil **24**, an exemplary embodiment can be made from a low - T_c superconductor such as commercially available, flexible, niobium-zirconium wire which can be readily formed into a coil.. Other embodiments, as noted above, of the energy-magnifying coil **24** can be made using a photoconductive material or a high - T_c superconductor. Most high - T_c superconductors (and some photoconductors) have ceramic-like properties and thus require the application of special methods for forming the material into a cylindrical coil having electrical continuity throughout. Some commercially available high - T_c superconductors are available in ribbon or tape form. The energy-magnifying coil **24** can be free-standing or supported on a rigid substrate.

By way of example, an energy-magnifying coil **24** can be made from a ribbon of flexible photoconductive material such as the material discussed in patent US 6,310,281, incorporated herein for reference. Briefly, a layer of stress-compliant metal is placed on a plastic ribbon. Then the photoconductive material is deposited on both sides of the metal-covered ribbon and the edges of the ribbon so that the ribbon is coated all the way around. Such a configuration allows low-mass electrons in the photoconductive material, to receive energy from inductive-photons emitted from the sending coil **20** on one side of the ribbon while re-radiating magnified energy from both sides of the ribbon.

In another example, a flexible photoconductor ribbon is made from flexible organic polymer having photoconductive properties. (High electrical conductivity observed in photoconductive polymers is attributed to the presence of low-mass electrons in the material). The flexible photoconductive ribbon can be wound on a dielectric tubular support, to form the energy-magnifying coil 24.

In yet another example, a thick-film coating of photoconductive cadmium sulphide (CdS) or cadmium selenide (CdSe) is formed on a wire coil by sintering as paste, which comprises a powder of finely ground CdS or CdSe crystals mixed with water and at least a fluidiser such as cadmium chloride, at a temperature of 550^0 C. to 600^0 C. in a controlled atmosphere. During sintering, the boundaries of the small crystals become melted with the heated fluidiser, allowing the crystals to regrow together and solidify when the fluidiser evaporates and the sintered coating is cooled. Alternatively, copper oxides are formed in place on bare copper or bronze wire by heating the wire above about 260^0 C. in an oxygen atmosphere, or by application of chemical oxidants.

In yet another example, a coil of ceramic-like superconductor or photoconductor is made by tape-casting, extruding, slip-casting, cold or hot-pressing, or coating of the material as a thin film arranged helically on a tubular dielectric substrate. The assembly is heat-treated in a controlled atmosphere furnace to increase inter-crystalline contacts. Alternatively, the thin film of superconductor or photoconductor is formed over the entire exterior of the dielectric substrate, followed by removal of selected portions of the superconductor or photoconductor to form the desired helical coil.

[121]In some photoconductors and doped semiconductors, only a small portion of a population of inductive photons irradiated on the material, impact with, and yield acceleration of, low-mass electrons in the material. This is due to a low density of photoconductive low-mass electrons in the material. In such as case, inductive-photon radiation passing through the material can be captured efficiently by normal free conduction electrons in a metallic strip that desirably is in immediate contact with, or embedded in, the material. The acceleration of normal free electrons in the metallic conductor, sets up an electric field that assists in accelerating the low-mass photoelectrons. In this configuration, it is desirable that the photoconductive material be disposed completely over and around the metallic strip so that the photoconductor faces both outwards and inwards, with both sides of the photoconductor or doped semiconductor being in electrical contact with each other.

One factor in the choice of photoconductor material to use in forming the energy-magnifying coil **24** is the potential magnification of energy that can be realised by low-mass electrons of an n-type or p-type photoconductive material. Other important factors are the quantity of low-mass electrons that are available in the photoconductive material for a given amount of illumination and the actual electrical conductance of the material. Standard illumination-sensitivity measurements provide a general overall index of the ability of a photoconductor to serve effectively in magnifying energy.

Cadmium sulphide and cadmium selenide, the most common photoconductive compounds which are available commercially, have calculated magnification factors of 37 and 59, respectively. The peak response wavelength of cadmium sulphide is 515 nanometers (in the green part of the visible spectrum) and of cadmium selenide is 730 nanometers (in the near-infrared part of the spectrum). Cadmium sulphide can be mixed with caesium selenide under certain conditions, so the resulting mixture assumes photoconductive characteristics between those two values. Mixtures can be produced having peak wavelengths which are matched to the wavelengths of commercially available LEDs of many sizes and illumination intensities. Some semiconductors which become photoconductive at a wavelength smaller than the wavelength produced by currently available LEDs can be made conductive of low-mass electrons merely by heating.

Applicant has found that gallium arsenide develops considerably higher conductivity than copper or silver at a temperature of 100^0 C. and that the conductive electrons are low-mass. Also, alpha radiation is capable of liberating many low-mass electrons in some semiconductors. A second electron of comparatively low mass may have been liberated from cupric oxide by alpha radiation along with the outer copper electron in Leimer's (1915) experiments, since the measured energy magnification exceeded the magnification calculated from cyclotron resonance of CuO, which most likely pertains only to the mass of the outer electron.

Dopants can be added to a semiconductor to make it more conductive of low-mass electrons without illumination. Also, the illumination-sensitivity and conductivity of cadmium sulphide are increased by adding small amounts of donor-type dopants such as, but not limited to, sulphides, selenides, tellurides, arsenides, antimonides and phosphides of the Type-IIIa elements: aluminium, gallium, indium and thallium. In this regard, the photoconductors of high-sensitivity photovoltaic cells may comprise as many as five different compounds. The actual mixtures of photoconductive compounds and dopants used in commercially available photovoltaic cells often are trade secrets. But, the sensitivity and conductances of the cells are usually given or are measurable, and these data can be used advantageously in selecting a particular photoconductive compound for use in the apparatus.

Other photoconductive compounds or elements can be employed in energy-magnifying coils. For example, the conduction electrons of silicon have an energy-magnification factor of 15 times. Photoconductors having very high magnification factors include, but are not limited to, gallium arsenide, indium phosphide, gallium antimonide, cadmium-tin arsenide, and cadmium arsenide, which have calculated energy-magnification factors ranging between 200 times and 500 times, and mercury selenide (1100 times), indium arsenide (2000 times), mercury telluride (3400 times) and indium antimonide (5100 times).

The depth of optical transmission largely determines the optimum thickness of photoconductive films for energy-magnifying coils. For example, the highest optical transmission of sintered CdS is reported to be 20 micrometers, but since the average grain size increases (and the average porosity decreases) with an increase in film thickness, the maximum conductivity of a sintered film is at a thickness of 35 micrometers (J. S, Lee et al., 1987).

The metal chosen to be embedded must not react chemically with the photoconductor. For example, aluminium reacts with gallium arsenide (GaAs) in an electrical environment, to change the conductive character of both the GaAs and the aluminium. Gold, platinum, and palladium can serve in many cases because these materials are relatively inert chemically. Gold combines chemically with tellurium, however, so gold is not suitable for embedding in mercury telluride. Cadmium plating over a common metal serves to alleviate the reactivity in cases where cadmium sulphide or cadmium selenide is used as the photoconductor.

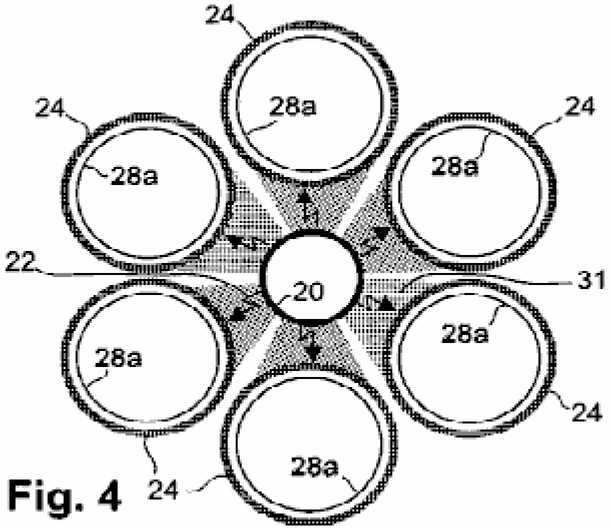

Fig. 4

The discussion above has been, for ease of explanation, in the context of the apparatus including one energy-magnifying coil **24**. However, as discussed, use of a single energy-magnifying coil **24** to capture inductive photons from the sending coil **20**, results in loss (by non-capture) of most of the inductive photons from the sending coil **20**. This proportion of captured inductive photons can be increased greatly in an embodiment in which multiple energy-magnifying coils **24** substantially completely surround the sending coil **20**, such as shown in **Fig.4**. In this embodiment, the energy-magnifying coils **24** substantially completely surround the sending coil **20**, and (although six energy-magnifying coils **24** are shown) as few as three energy-magnifying coils **24** of adequate diameter, still could substantially completely surround the sending coil **20**. There is no limit, except as possibly related to packaging concerns, to the maximum number of energy-magnifying coils **24** which could be used. The depicted configuration of **Fig.4**, has a desirable number of six energy-magnifying coils **24**. In **Fig.4**, the shaded sectors **31**, considered collectively, illustrate that nearly all 360 degrees of inductive-photon radiation **22** from the sending coil **20**, are received by the energy-magnifying coils **24**. Not shown in **Fig.4** are photoconduction exciters (items **26** in **Fig.3**) used for illuminating respective portions of the energy-magnifying coils **24** in a photoconductive form of the apparatus **15**.

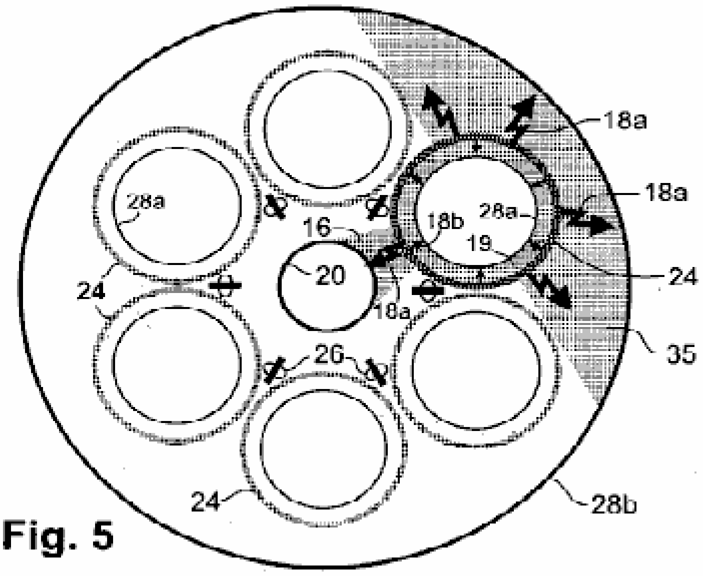

Fig. 5

Fig.4 also depicts respective internal output coils **28a** nested co-axially and co-extensively inside each of the energy-magnifying coils **24**. As discussed earlier, each internal output coil **28a** receives nearly all the inductive-photon radiation propagating radially inwards from the respective energy-magnifying coil **24**. Desirably, the overall energy output of the embodiment of **Fig.4**, can be increased by surrounding the array of energy-magnifying coils **24** with an external output coil **28b**, of which the conductors desirably are made of insulated metallic wire (**Fig.5**). In this embodiment, approximately half of the outwardly propagating magnified inductive-photon radiation (large arrows **18**) from each energy-magnifying coil **24** (one such coil is highlighted in **Fig.5**) is received by the external output coil **28b**. This captured radiation is denoted by the shaded sector **35**. When this externally directed inductive radiation captured from all the energy-magnifying coils **24** is added to all the inwardly directed radiation captured from the energy-magnifying coils **24** by their internal output coils **28a**, **28b**, greatly exceeds the back-force energy directed by the energy-magnifying coils **24** towards the sending coil **20** (the back-force energy from one energy-magnifying coil **24** is shown as the shaded sector **16**). Thus, the resulting energy "leverage" exhibited by the apparatus is increased substantially by including the external output coil **28b**.

The embodiment of **Fig.5** also includes respective arrays (viewed endwise) of light-emitting diodes (LEDs) collectively serving as photoconductor exciters **26** for the energy-magnifying coils **24**. The LED arrays are arranged back-to-back and disposed between adjacent energy-magnifying coils **24**. Each array in **Fig.5** can comprise multiple LEDs or as few as one LED.

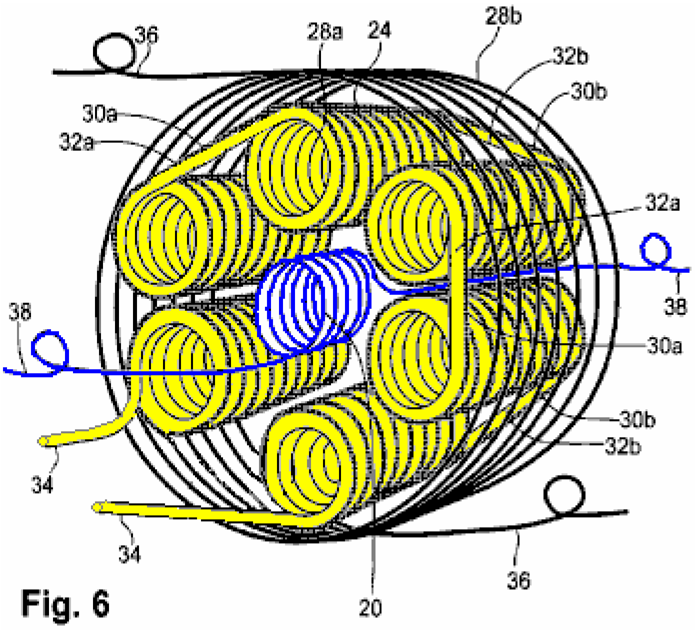

Fig. 6

Fig.6 provides a perspective view of an apparatus **15** having an arrangement of coils similar to the arrangement shown in **Fig.5**. In **Fig.6**, each energy-magnifying coil **24** comprises a helical coil of superconductive or photoconductive material in wire or ribbon (tape-like) form.

Whenever multiple energy-magnifying coils **24** are used, the respective directions of electron flow in them desirably occur in the same circular direction as viewed endwise. Thus, the flow of electrons in all the energy-magnifying coils **24** is clockwise during one phase of an oscillation cycle and counterclockwise during the other phase. The same principle applies to the flow of electrons in the output coils **28a**, **28b**. (But, in such an embodiment, the flow of electrons in the output coils **28a**, **28b**, is in the opposite direction to the electron flow in the energy-magnifying coils **24**). These relationships of electron flow in the coils during a particular phase of an oscillation cycle, are shown in **Fig.7**.

The energy-magnifying coils **24** desirably are connected together in series, using inter-coil connectors **30a**, **30b**, to maintain the same direction of electron flow, which can be clockwise or counterclockwise (as viewed from one end of such a coil). This direction of electron flow in a coil is termed the “handedness” of the coil. If the energy-magnifying coils **24** all have the same handedness, then the ends of adjacent energy-magnifying coils **24** are connected together in a head-to-foot manner progressively in one direction around the group of coils (not shown). (“Head” refers to the forward-facing end, and “foot” refers to the rearward-facing end of the apparatus in relation to the viewer). In this case, the inter-coil connectors **30a**, **30b**, must pass either completely through the apparatus or around the outside of the apparatus for its entire length, which reduces efficiency and can cause undesirable wear if the connectors are subjected to vibrations. A more desirable arrangement is depicted in **Fig.6**, in which short inter-coil connectors **30a**, cross directly head-to-head between one energy-magnifying coil **24** and an adjacent energy-magnifying coil **24**, and short inter-coil connectors **30b** cross over directly foot-to-foot in the next energy-magnifying coils **24**. In this configuration, the handedness of turns of the energy-magnifying coils **24** alternates from right-to-left to left-to-right in adjacent energy-magnifying coils **24**. In the same manner as a right-handed screw advances from head to foot as it is turned clockwise, and a left-handed screw moves in the opposite direction, clockwise electron flow in a right-handed coil advances from head to foot, and clockwise electron flow in a left-handed coil advances from foot to head.

The single-layered internal output coils **28a** in **Fig.6**, present the same situation in which these coils are connected in series. Desirably, the inter-coil connectors **32a** cross over directly from one internal output coil **28a** to the adjacent internal output coil **28a**, head-to-head and the inter-coil connectors **32b** cross over directly foot-to-foot from one internal output coil **28a** to the adjacent internal output coil **28a**. This same handedness convention generally applies to all series-connected internal output coils **28a** connected in this manner. The head-to-head inter-coil connectors **32a** and foot-to-foot inter-coil connectors **32b** for the internal output coils **28a**, need not coincide with the same respective connectors **30a**, **30b** for the energy-magnifying coils **24**.

In another embodiment (not shown), each internal output coil is two-layered, with both leads at either the head or foot. Such a configuration allows for short and direct connections between adjacent internal output coils. Multiple-layered internal output coils may be more efficient, but the extra layers of coiled wire increase the mass of the apparatus, which may be a concern in mobile applications. Multiple wire layers carrying high current may also result in overheating, which may require that some space be left between each internal output coil **28a** and its surrounding energy-magnifying coil **24** to accommodate one or more conduits of a coolant through the apparatus (at a sacrifice of some efficiency). The coolant can be, for example, forced air (in the case of photoconductors or doped semiconductors) or liquefied cryogenic gas (in the case of superconductors).

Fig.6 also shows two external conductors **34** connected to respective internal output coils **28a**. Electrons flow through the conductors **34** and the internal output coils **28a** in series. In addition, two external conductors **36** are connected to respective ends of the external output coil **28b**, and two external conductors **38** are connected to respective ends of the sending coil **20**.

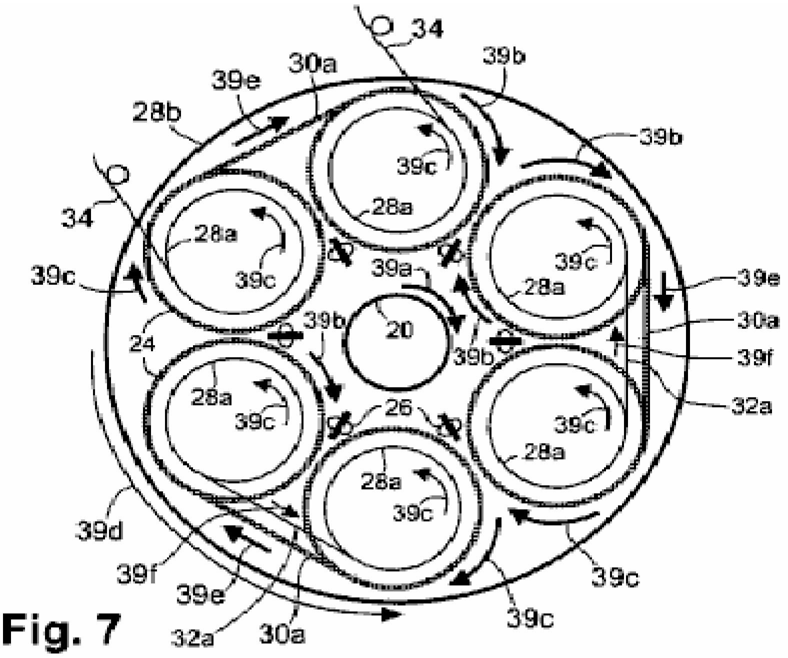

Fig. 7

Fig.7 is a schematic end view of the apparatus of **Fig.6**, showing the relative direction of electron flow in the various coils and in the inter-coil connections described for single-layer coils. At a particular oscillation phase, the clockwise electron flow denoted by the arrow **39a** in the sending coil **20** induces clockwise electron flow **39b** in all the energy-magnifying coils **24**. The magnified radiation from the clockwise electron flow in the energy-magnifying coils **24**, induces counterclockwise electron flow in all the internal output coils **28a**, as indicated by the arrows **39c**. The counterclockwise electron flow, denoted by the arrow **39d**, in the external output coil **28b** is opposite in direction to the electron flow in the energy-magnifying coils **24**.

The electron flow in the inter-coil connectors **30a** extending between adjacent energy-magnifying coils **24** is indicated by the arrows **39e**, and the electron flow in the inter-coil connectors **32a** extending between adjacent internal output coils **28a** is indicated by the arrows **39f**. During the next oscillation phase, all the direction arrows shown in **Fig.7** reverse themselves.

Connecting the internal output coils **28a** together in series is advantages if it is desired to maximise the output voltage from the apparatus **15**. Alternatively, the internal output coils **28a** can be connected together in parallel if it is desired to maximise the output electrical current from the apparatus **15** while minimising the output voltage. In this alternative configuration, all the internal output coils **28a** desirably are wound with the same handedness, with each coil **28a** having two respective leads. The leads at one end (e.g., the foot end) of the coils **28a** are connected to each other, and the leads at the other end (the head end) of the coils **28a** are connected to each other. The resulting parallel-coil system is connected in a conventional manner in other circuitry of the apparatus (not shown).

Further alternatively, the internal output coils **28a** can be connected together so as to provide more than one output circuit (so long as sufficient energy is produced for use as feedback to the sending coil **20** and for use in establishing favourable conditions for producing abundant low-mass electrons). Alternatively, the relative voltage(s) and current(s) of output power can be varied by changing the ratio of the number of turns in the energy-magnifying coils **24** to the number of turns in the internal output coils **28a**. Alternatively again, the energy-magnifying coils **24** can be employed in a separate manner to provide more than one energy-magnifying unit. Each unit can comprise one or more energy-magnifying coils that can serve its respective circuit of internal output coils.

The two conductors **36** connected to the external output coil **28b**, can be connected to the internal output coils **28a** or can be used (without being connected to the internal output coils **28a**) with only the external output coil **28b** to provide an independent output circuit (not shown). The two conductors **38** connected to the sending coil **20**, are connected in the feed-back loop **46** such that electron flow in the sending coil **20** is in the same circular direction as in the internal output coils **28a**.

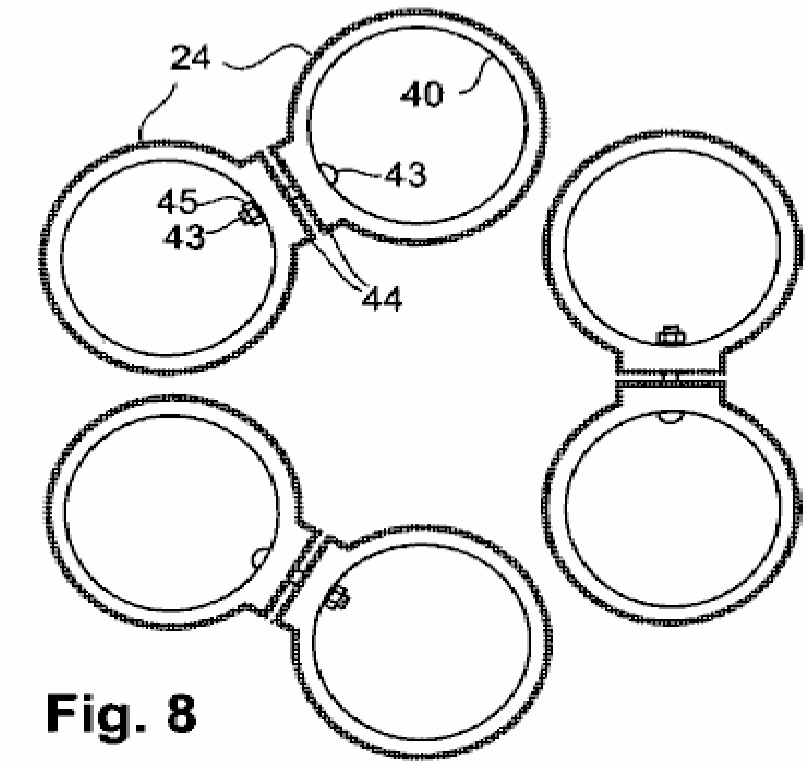

Fig. 8

Fig.8 depicts yet another embodiment of the apparatus **15**, in which each energy magnifying coil **24** comprises a thin film or thick film of a polycrystalline or other suitable photoconductor deposited in a helical manner directly on to a tubular substrate **40** desirably made of ceramic or other suitable dielectric material. on each energy magnifying coil **24**, the polycrystalline photoconductor is formed as a helical band on the outside of the tubular substrate **40**. The helical band of photoconductor can include a thin film of metal embedded within it. In certain cases, inter-coil connections between adjacent energy magnifying coils **24** can be made by extending the deposited photoconductor from the helices to contact areas **44** situated at the ends of the tubular substrates **40** and extending toward contact areas **44** on adjacent tubular substrates **40**. Electrical contact between adjacent energy magnifying coils **24** is made under moderate pressure via the contact areas **44**, which are shown in **Fig.8**. To distinguish the individual contact areas **44**, they are shown in a separated position before being pressed together to make contact. To maintain the integrity of the contact areas **44**, the energy magnifying coils **24** can be held together in mutual proximity by any of various non-metallic fasteners to make continuous electrical contact between all of the photoconductive portions. For example, bolts **43** and nuts **45** made of a plastic such as nylon, or other dielectric material, can be used. Another variation is to maintain contact pressure of one coil to the next by means of spring clips. Thus, in one embodiment, the energy magnifying coils **24** are connected so as to be in endless contact with each other, with no capacitative break between them. The remainder of the apparatus can be constructed in the same manner as the photoconductor or doped-semiconductor embodiment described above, wherein the same attention to the direction of electron flow in respective coils is observed.

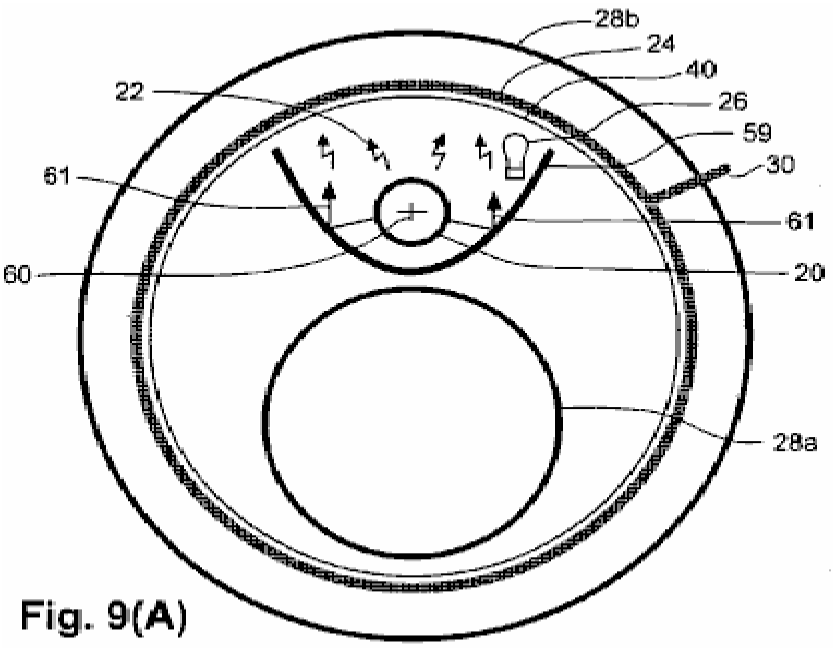

Fig. 9(A)

The coil configuration of yet another embodiment is shown in **Fig.9A** and **Fig.9B**. A tubular substrate **40**, supports a helical, thin film or thick film, dipole-type of energy-magnifying coil **24** that is nested inside and coaxial with a single external output coil **28b**. Nested inside the tubular substrate **40**, and with respective axes parallel to the axis of the tubular substrate **40**, are a sending coil **20** and an internal output coil **28a**. The sending coil **20** and the internal output coil **28a**, are positioned on opposite sides of a reflective metallic separator **59**. The separator **59** is substantially parabolic in cross-section throughout its axial extent, and is positioned so that the longitudinal edges are touching, or nearly touching, the tubular substrate **40**. The separator **59** can be composed of common, non-magnetic metal such as aluminium or magnesium. The sending coil **20** is positioned on the concave side of the separator **59**, with the axis of the sending coil **20** being positioned at the geometric focus **60** of the parabola and disposed parallel to the axis of the energy-magnifying coil **24**. The energy-magnifying coil **24** in this embodiment, comprises a thin film or thick film photoconductor formed helically on the tubular substrate **40**. A photoconduction exciter **26** is positioned inside the separator **59**. (The tubular substrate **40**, is made of a rigid material that is transparent to radiation produced by the photoconduction exciter **26**). All the other forms of the energy-magnifying coil **24** as described herein, including the superconducting form, can be employed in this embodiment.

The separator **59**, serves a double purpose. One purpose is to direct towards the energy-magnifying coil **24** the portion of the inductive-photon radiation **22** which is not otherwise directed towards the separator, as shown by the reflected-photon rays **61** in **Fig.6A**. (Reflection of these radiated photons does not change the directionality of the transverse force which these photons convey). Another purpose of the separator **59** is to serve as a shield to restrict the amount of inward radiation **18b** from the energy-magnifying coil **24** which is returned as a back-force to the sending coil **20**. The restricted back-force radiation is shown by the shaded area **63** in **Fig.9B**.

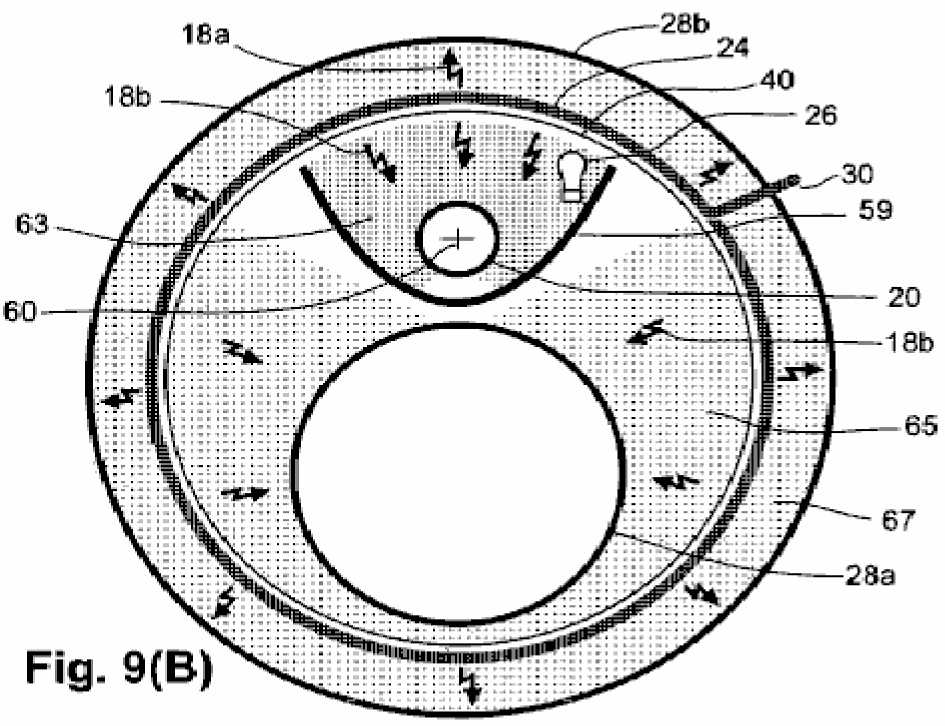

Fig. 9(B)

The portion of the inwardly directed, magnified inductive-photon radiation **18b** which is received by the internal output coil **28a**, is denoted by the shaded area **65**. The proportional amount of outwardly directed magnified radiation **18a** from the energy-magnifying coil **24** which is received by the external output coil **28b**, is shown by the shaded area **67**. The sum of the magnified radiation in the area **65** which reaches the external output coil **28b**, substantially exceeds the magnified radiation in the area **63** (the latter serving as a back-force on the sending coil **20**). This excess of utilised energy over the back-force energy, provides energy leverage. This embodiment also includes a starting mechanism, and initial power source for the photoconduction exciter, a work loop, and a feedback loop (not shown) as provided in the other embodiments described herein.

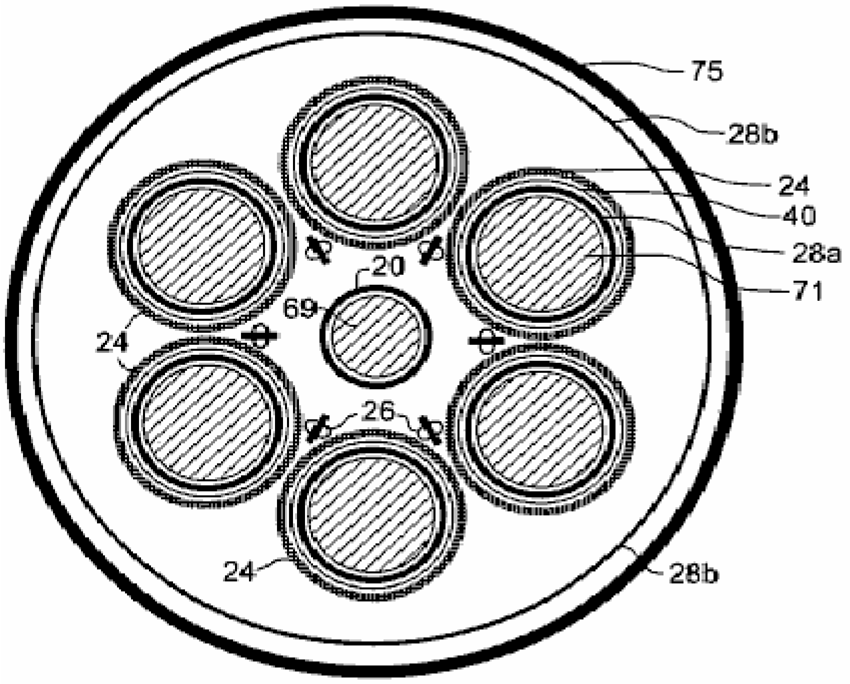

Fig. 10(A)

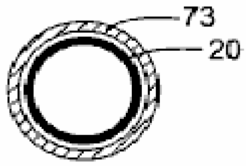

Fig. 10(B)

Certain features can be incorporated with any of the embodiments described herein, to add functional practicality. For example, referring to the schematic representation of a coil configuration shown in end view in **Fig.10A**, a ferromagnetic core **69** can be placed inside the sending coil **20**, and ferromagnetic cores **71** can be placed inside respective internal output coils **28a**. These cores increase the inductance of the apparatus, which lowers the frequency of the electrical oscillations produced by the apparatus. Although increases in inductance can cause the output voltage and current to be out of phase, the phase difference can be corrected by adding capacitance to the circuitry by conventional means. Also shown, is an external metal shield which completely surrounds the apparatus to block any radiation from the device that could interfere with radios, televisions, telephones, computers and other electronic devices. the shield can be comprised of any of various non-magnetic metals such as aluminium or magnesium.

An alternative means of increasing the inductance of the apparatus is shown in **Fig.10B**, which is a variation of the end view of just the sending coil **20** that is depicted in **Fig.10A**. In **Fig.10B**, a ferromagnetic sleeve **73** is placed coaxially around the sending coil **20**.

The respective dimensional ratios of various components generally remain similar with respect to each other for different apparatus sizes, except for the longitudinal dimension, which generally can be as short or as long as desired, up to some practical limit. The respective gauges of wires used in the sending coil **20** and the output coils **28a** and **28b**, are commensurate with the electric current carried by these wires, and the respective thickness of insulation (if used) on the wires is commensurate with the voltage.

The outside diameter of the internal output coils **28a** desirably is only slightly less than the inside diameter of the respective energy-magnifying coils **24**, as shown in **Fig.6**, **Fig.7** and **Fig.8**, thereby ensuring close proximity of each internal output coil **28a** with its respective energy-magnifying coil **24**. At a sacrifice in efficiency, the outside diameter of the internal output coils **28a** can be made smaller, to allow space for heat from the current-carrying wires to escape or be removed by a coolant such as forced air in the case of a photoconductor type or doped semiconductor type apparatus, or by a cryogenic liquefied gas in the case of a superconductor type apparatus.

Also, desirably, the external output coil **28b** is connected in series with the internal output coils **28a** to maximise the output voltage from the apparatus **15** and to minimise heat produced by electric currents in the apparatus. The output voltage can be stepped down and the output electric current stepped up to normal operating ranges by using a transformer, wherein the primary of the transformer would comprise the load in the work loop **48**.

As discussed above, each energy-magnifying coil **24** can comprise a photoconductor or doped semiconductor formed as a helical pattern on a respective thin-walled tubular substrate provided with extended, raised contact surfaces at each end. The energy-magnifying coils **24** desirably are connected electrically (rather than capacitatively) to each other in series at the raised contact surfaces. The photoconductive coils desirably are coated using clear varnish or enamel to provide electrical insulation and to protect the photoconductors from oxidation and weathering.

Where the low-mass photoconducting electrons in the energy-magnifying coils **24** are present in a concentration which is insufficient for capturing most of the inductive-photon radiation from the sending coil **20**, each energy-magnifying coil desirably includes a thin metallic band. The metal desirably is in intimate contact with the low-mass-electron carrier. the metal can be on the exterior of a doped semiconductor, or it can be embedded in a photoconductor band of the coil to capture the inductive radiation and set up an electric field which, in turn, assists in accelerating the low-mass electrons. In the photoconductive embodiment, the photoconductive material desirably is disposed all around the metallic band so that the low-mass electrons are conducted on the outer side as well as the inner side and edges of the photoconductive band on the portion or portions which are exposed to illumination on the outside. The width of the metal band desirably is sufficient to capture as much of the inductive-photon radiation from the sending coil as is practical, since gaps between turns of the metal band in the energy-magnifying coil permit the sending coil's inductive radiation to pass through to the internal output coil. Since the sending coil's radiation is a half-cycle out of phase with the inductive radiation from the low-mass electrons, all the sending coil radiation which reaches the output coil, reduces the output efficiency of the apparatus.

Appropriate photoconductive materials (e.g. cadmium sulphide, cadmium selenide) for forming the energy-magnifying coils **24** are commercially available. The photoconductive material can be a single material or a mixture of materials, and can be formed by, for example, sputtering. A mixture of cadmium sulphide and cadmium selenide can be adjusted optimally to yield energy-magnifying coils exhibiting maximal energy-magnifying factors at a peak wavelength matching the brightest photoconduction exciters **26** which are available.

With respect to the photoconduction exciters **26**, photo-excitation of the energy-magnifying coils **24** can be provided by one or more LEDs, either surface-emitting or edge-emitting, for example, selected to produce an output wavelength matched to the peak photoconduction wavelength of the energy-magnifying coils **24**. In the embodiment of **Fig.7** and **Fig.10A**, individual LEDs **26** are positioned in linear arrays mounted back-to-back on respective mounting bars. The assembled mounting bars with LEDs are placed in the gaps between adjacent energy-magnifying coils **24** to illuminate at least the sides of the respective energy-magnifying coils **24** which receive inductive-photon radiation from the sending coil **20**. LEDs are advantageous compared to incandescent lamps because LEDs produce more light with less heat and have a much longer operational lifetime than incandescent lamps. LEDs are also preferred because of their small size which facilitates fitting a large number of them into the relatively small space between adjacent energy-magnifying coils **24**.

Whereas the invention has been described in connection with several representative embodiments, the invention is not limited to those embodiments. On the contrary, the invention is intended to encompass all modifications, alternatives and equivalents as may be included within the spirit and scope of the invention, as defined by the appended claims.

JOHN REARDON: AC GENERATOR

US Patent 6,946,767 20th September 2005 Inventor: John Reardon

ALTERNATING CURRENT GENERATOR

This is a reworded excerpt form this patent which shows a high-efficiency electrical generator of alternating current. It is stated that this generator design is not affected by Lenz's law and the experimental results showed a 13,713% improvement over conventional power output.

ABSTRACT

An alternating current electrical generator creates three different and distinct magnetic fields between wound coil elements and rotating magnets, two fields of which are induced fields caused by magnet rotation. A plurality of magnets are positioned such that they extend outwardly from a rotating shaft. The magnets are circumferentially spaced around the shaft such that the north polar end of one magnet follows the south polar end of the next magnet or such that the polar end of one magnet follows a magnet with the same polar end. A plurality of stationary coil elements are positioned in spaced relation to the magnets. The coil elements each have electrical windings and metal cores which extend the lengths of the coil elements. The magnets rotate in spaced relation to the ends of the coil elements in such a way that the magnets' flux lines cut the cores located at the centre of each of the coil elements. This induces alternating electric current that oscillates back and forth along the lengths of the cores. This oscillating current creates an expanding and collapsing set of magnetic flux lines which expand and contract through every inch of the coil element's windings. This expanding and collapsing magnetic field induces an expanding and collapsing magnetic field and an alternating electric field in the coil elements.

BACKGROUND OF THE INVENTION

Alternating current generators are rotating devices which convert mechanical energy into electrical energy. To generate an electromotive force by mechanical motion, there must be movement between an electric coil and a magnetic field in a manner that will cause a change in the flux that passes through the coil. Fundamentally, the induced electromotive force is brought about by a change in the flux passing through the coil.

The use of electromagnets, magnets and magnet components in generators to create the magnetic field and its subsequent effect on electric coils to ultimately generate electric current is well known. Such magnetic generators operate by using the repelling forces created by the effect of changing polarities of both permanent and electromagnets. For instance, there are electrical generating devices which employ electromagnets which are fixed in position and which induce current by being selectively energised, as iron or other magnetic metal discs, bars, or similar elements are rotated at or around the magnets. Other systems employ electromagnet or permanent magnets which are rotated, by various means, in relation to iron cores or coils, inducing an alternating electrical current within the coils.

However, prior alternating current generators which employ rotating magnet systems are inefficient and generally fail to deliver adequate current, in relation to the mechanical effort applied.

SUMMARY OF THE INVENTION

It is thus an object of the present invention to address the limitations and disadvantages of prior alternating electric current generators.

It is an object of the present invention to provide an alternating current generator which generates a substantial amount of electrical current efficiently and effectively.

It is a further object of the present invention to provide an alternating current generator which employs rotating magnets to induce increased alternating electrical current within the iron cores of electrical coils.

It is still another object of the present invention to provide an alternating current generator which can be simply and readily manufactured and be operated with high efficiency.

These and other objects are obtained by the present invention, an alternating current electrical generator which creates three different and distinct magnetic fields between wound coil elements and rotating magnets, two fields of which are induced fields caused by magnet rotation. A plurality of magnets are positioned such that they extend outwardly from a rotating shaft. The magnets are circumferentially spaced around the shaft such that the north polar end of one magnet follows the south polar end of the next magnet or such that the polar end of one magnet follows a magnet with the same polar end. A plurality of stationary coil elements are positioned in spaced relation to the magnets. The coil elements each have electrical windings and metal cores which extend the lengths of the coil elements. The magnets rotate in spaced relation to the ends of the coil elements in such a way that the magnets' flux lines cut the cores located at the centre of each of the coil elements. This induces alternating electric current that oscillates back and forth along the lengths of the cores. This oscillating current creates an expanding and collapsing set of magnetic flux lines which expand and contract through every inch of the coil element's windings. This expanding and collapsing magnetic field induces an expanding and collapsing magnetic field and an alternating electric field in the coil elements.

The novel features which are considered as characteristic of the invention are set forth in particular in the appended claims. The invention itself, however, both as to its design, construction, and use, together with additional features and advantages thereof, are best understood upon review of the following detailed description with reference to the accompanying drawings.

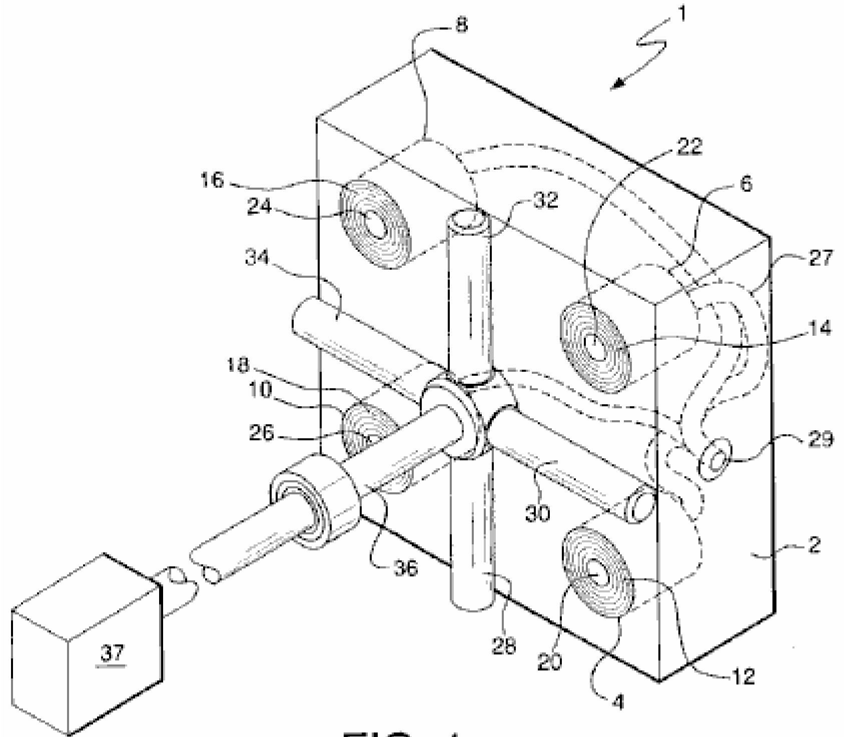

FIG. 1

Fig.1 and **Fig.2** show a clear depiction of the components of alternating current generator 1 of the subject invention. Generator 1 comprises housings **2** and **3**. For simplicity purposes and ease of understanding, only housing 2 is shown in **Fig.1**. It must be understood, however, that generator 1 of the present invention is configured for use with both housings **2** and **3**. Housing **2** contains coil elements **4**, **6**, **8** and **10**. Each coil element comprises multiple windings **12**, **14**, **16**, and **18**, respectively, wound around inner steel or similar metal cores **20**, **22**, **24**, and **26**, respectively. Each steel core extends the full length and directly through each of the coil elements. Coil elements **4**, **6**, **8**, and **10** are mounted within housing **2**, such that the end surfaces of the coil elements and the ends of cores **20**, **22**, **24**, and **26** are positioned flush with the external surface of housing **2**.

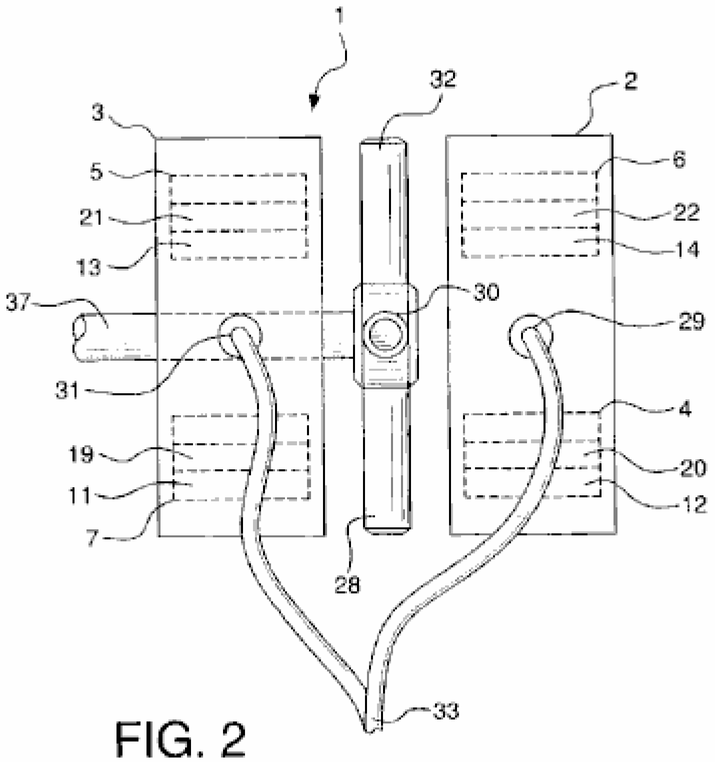

FIG. 2

Housing **3** also contains four coil elements positioned identically as has been described with regard to housing **2**. Two of these coil elements **5** and **7** are shown in **Fig.2**. Coil element **5** has multiple windings **13** and centre core **21** and coil element **7** has multiple windings **11** and centre core **21**.

Magnets **28**, **30**, **32**, and **34** are secured to shaft **36**, which is configured to be rotated by conventional power source **37**, such as a diesel engine, turbine, etc. Magnets **28**, **30**, **31**, and **32** all have ends with outwardly extending polarities. Magnets **28**, **30**, **32**, and **34** are positioned in spaced relation to the ends of exposed cores **20**, **22**, **24** and **26** of coil elements **4**, **6**, **8**, and **10** and in spaced relation to the ends of the four exposed cores in the four coil elements located in housing **3**, cores **19** and **21** being shown in **Fig.2**. All magnets are equidistantly spaced on and around shaft **36**, such that the outwardly extending pole of one magnet circumferentially follows the outwardly extending pole of the next magnet. The north polar end of one magnet may follow the south polar end of the next magnet or the polar end of one magnet may follow a magnet with the same polar end.

While four magnets and four cores are shown, it is contemplated that additional magnets and cores could be employed in the generator. Also, while permanent magnets are shown in the drawings, electromagnets could also be used, as they produce the same magnetic flux.

Alternating electrical current is generated when power source **37** rotates shaft **36**, thus causing rotation of magnets **28**, **30**, **32**, and **34** in spaced, adjacent relation to the ends of cores **20**, **22**, 24, and **26** of coil elements **4**, **6**, **8**, and **10**, and in spaced, adjacent relation to the ends of cores **19** and **21** of coil elements **7** and **5** and the ends of the cores of the other two similarly aligned coil elements in housing **3**. The current which is generated is transmitted through electrical conductive wiring **27**, which merges at connection points **29** in housing **2** and **31** in housing **3**, for the consolidated transmission at connection point **33** of the electricity produced.

As best represented in **Fig.2**, when magnet **28** is rotated in space relation to the end of core **20** of coil element **4**, flux lines **100** of the magnet cut the core at the centre of the coil element. This induces an alternating electrical current that oscillates back and forth along the length of core **20**. This oscillating current creates an expanding and collapsing set of magnetic flux lines **200** which expand and contract through every inch of coil windings **12**. Expanding and collapsing field **200** induces an alternating electric field in coil element **4** which is accompanied by an expanding and collapsing magnetic field **300**. It is noted, significantly, that none of the magnetic field lines **100**, **200** and **300**, act in a negative fashion or in an opposing action. This allows the subject invention to overcome the limitations of Lenz's law, which states that whenever there is a change in magnetic flux in a circuit, an induced electromotive force is set-up tending to produce a current in a direction which will oppose the flux change.

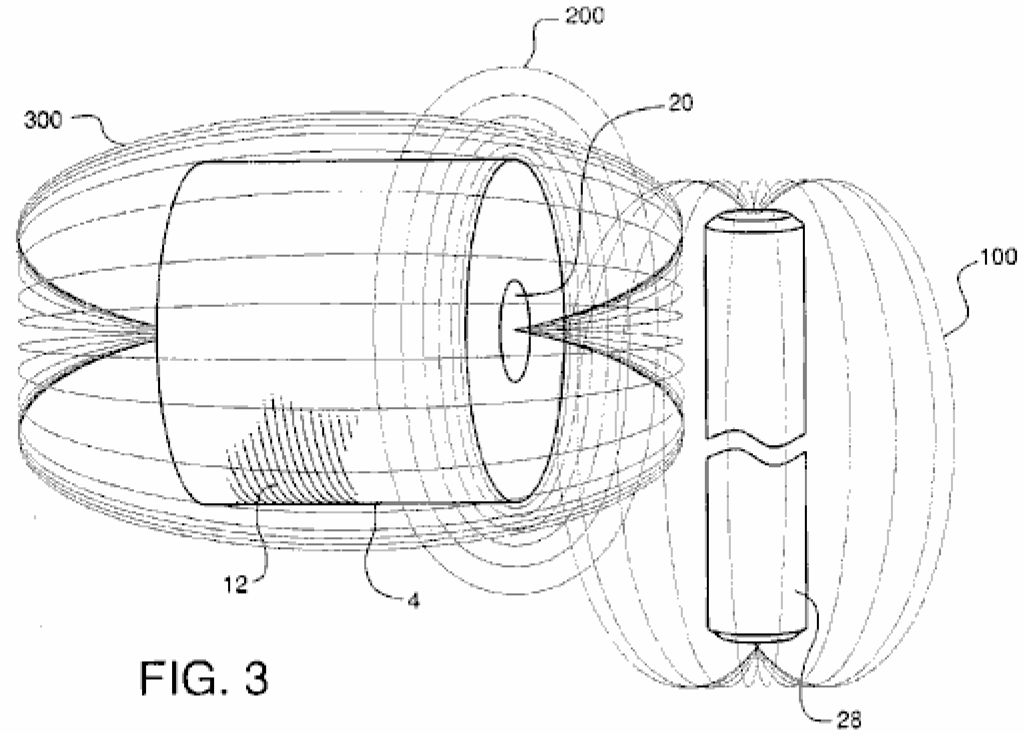

FIG. 3

Fig.3 illustrates an alternate embodiment of the invention to that which is shown in **Fig.1**. As shown in **Fig.3**, coil element **44** with outer windings **58** and inner steel core **66**, coil element **46** with windings **56** and core **64**, coil element **48** with windings **54** and core **62**, and coil element **50** with outer windings **52** and core **60** are positioned adjacent to rotor **67**, which is mounted on shaft **69**. Magnets **68** and **72** are mounted on rotor **67** such that the north poles of the magnets are positioned in spaced relation to coil elements **44**, **46**, **48** and **50**. Magnets **70** and **74** are mounted on rotor **67** such that the south poles of the magnets are also positioned in spaced relation to coil elements **44**, **46**, **48**, and **50**. All magnets are fixedly mounted on rotor **67** such that a north pole of one magnet circumferentially follows a south pole of the next magnet in line. The contemplated gap between the magnets and coil element cones is approximately 0.0001 of an inch, although the scope and use of the invention should not be deemed restricted to this distance.

As in the prior embodiment, rotation of magnets **68**, **70**, **72**, and **74**, by rotation of shaft **69** and hence rotor **67**, causes the flux lines of the magnets to cut cores **60**, **62**, **64**, and **66** of coil elements **44**, **46**, **48**, and **50**, eventually resulting in the output of electrical current as previously described.

It is noted that the larger the diameter of rotor **67**, the more coil elements can be positioned around the rotor. The greater the number of coil elements, the slower rotor **67** needs to rotate; however, there is a power loss in so doing. In addition, while rotor **67** is shown as being circular, it may be as square in shape or formed of as other appropriate multi-sided configurations.

This unique way of generating electricity allows generation of more electrical power, e.g. anywhere in the range of 4 to 137 times more power, than prior, conventional means. It also has the advantage of obtaining unity power with very little effort.

As evidence of such power gains, reference is made to the below outlined experimental outputs from coils and magnets which produced electric power the conventional way compared with the subject invention. The conventional way of generating power, for purpose of the following experimental outputs, as referenced herein, is accomplished by cutting the wires, not the cores, of the coil's windings with the magnet’s flux.

In this regard, proof is also provided that the herein described method of generating electrical power is not affected by Lenz's Law, by reference to the readings obtained by the conventional methods as the rpm and size of the coil increase. With conventional methods, the values do not change linearly, but are less because Lenz's Law restricts the outputs from increasing proportionally to the speed and size of the coil. In comparison, however, in the method of producing power of the subject invention, there is an increase in the readings of V (voltage), I (current), and P (power) which are actually larger than anticipated.

It is also noted that, just like a transformer, when the number of turns ratio is increased, V increases and I decreases, which is exactly what is seen at the various rpm readings for the different size coils. However, they do not increase or decrease proportionally.

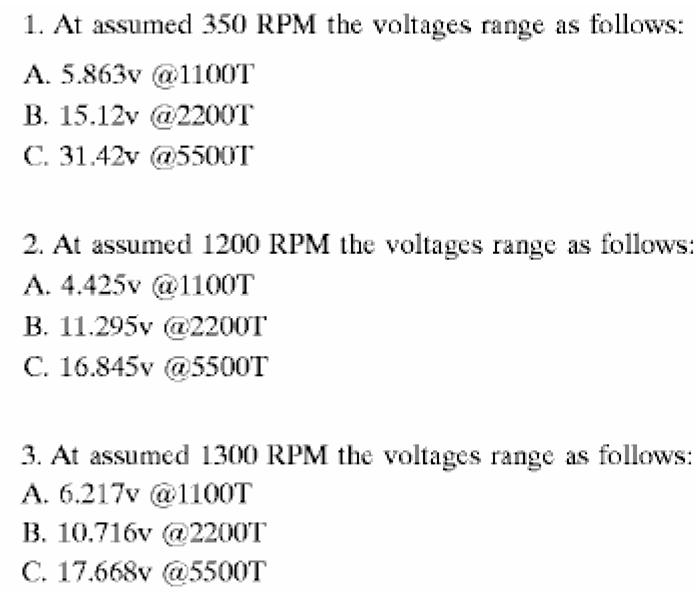
Thus, this presents the ideal model for producing electrical power that corresponds to the general law that states that as the speed increases, the voltage will increase proportionally, through the equation:
V = q (charge) × v (velocity) × B (magnetic field strength). This also holds true for a coil, in that transformers increase proportionally to the turns ratio.

With reference to the voltage outputs for each of the coils, 1100T, 2200T and 5500T, it is seen that they are consistent with the types of voltage outputs for a transformer action. That is to say, as the turns ratio goes up in a transformer so does the voltage. Since the increases in voltage between the number of turns is not exactly 2 to 5 times, one can pick any one of the coils and assume it is accurate and adjust the other coils accordingly. Thus, by fixing the 1100T coil, the other coils become 2837T and 5896T respectively. By fixing the 2200T coil, the other coils become 853T and 4572T respectively. And by fixing the 5500T coil, the other coils become 1026T and 2646T respectively. Also, if the adjustments are made as described here, i.e. that the coils are bigger than originally thought, and they are applied to the voltages for the conventional method of generating power, the voltages do not increase proportionally but are actually smaller than they are supposed to be, additional proof that Lenz's Law has application to conventional generators, but not to this invention.

The proportional changes in the voltage relative to speed can also be seen. Thus, considering the 350 RPM speed as accurate, the 1200 RPM and 1300 RPM speeds will adjust to 906 RPM and 1379 RPM respectively. Considering the 1200 RPM speed as accurate, the 350 RPM and 1300 RPM speed becomes 464 RPM and 1826 RPM respectively. And finally, considering the 1300 RPM speed as accurate, the 350 RPM and 1200 RPM speeds become 330 RPM and 854 RPM respectively.

It is noted that in using the various RPM readings based upon the above, it is seen that, in the conventional way of generating power, there are losses associated with the measured values. The calculated values again show the application of Lenz's Law in the conventional way of generating power, but not to this invention. In fact, whether or not there is an adjustment of RPM speed or coil size, the power generation of this invention is in no way affected by Lenz's Law.

Since Lenz's Law has no effect in this generator, it can be assumed that the voltages increase proportionally to the speed of the magnets rotation. Therefore, one can extrapolate the expected voltages at 1800 RPM, the speed necessary to create 60 Hz. With regard to this generator, for each of the three coils from the 350 RPM, 1200 RPM and 1300 RPM speeds, the following results (values are based on one coil/magnet.):



1. At assumed 350 RPM the voltages range as follows:

A. 5.863v @1100T

B. 15.12v @2200T

C. 31.42v @5500T

2. At assumed 1200 RPM the voltages range as follows:

A. 4.425v @1100T

B. 11.295v @2200T

C. 16.845v @5500T

3. At assumed 1300 RPM the voltages range as follows:

A. 6.217v @1100T

B. 10.716v @2200T

C. 17.668v @5500T

The reason the current is not changing linearly as the laws of physics imply from transformers, i.e. as voltage goes up based on the number of turns, the current goes down proportionally to the voltage gain, is due to the fact that the inductive reactance is also going up. See the following chart for the inductive reactances for each coil at each speed.

Impedance (Z) or inductive reactance (X(L)) for a circuit with only a coil in it is the AC voltage divided by the AC current, and the inductance (L) is Z/2 × pi × F (frequency). For a circuit with a resistor and a coil
Z = square root of (R (resistance) squared + X(L) squared)).

The following is the chart of impedance Z for all coil sizes at all speeds for the conventional method of generating power and the method of generating power with this invention:

Where:
"T" stands for Turns,
"CM" stands for Conventional Method and
"SI" stands for Subject Invention:

(1) For 350 RPM for 1100T, 2200T and 5500T coils,

1. (a) CM: 0.57v / 56.6 mA = **10.021** ohms = Z
(b) SI: 1.14v / 106.6 mA = **10.694** ohms = Z

2. (a) CM: 0.93v / 32.4 mA = **28.704** ohms = Z
(b) SI: 2.94v / 70.1 mA = **41.94** ohms = Z

3. (a) CM: 2.09v / 17.3 mA = **120.81** ohms = Z
(b) SI: 6.11v / 37.9 mA = **161.21** ohms = Z

(2) For 1200 RPM for 1100T, 2200T and 5500T coils:

1. (a) CM: 1.45v / 60.2 mA = **23.387** ohms = Z
(b) SI: 2.95v / 141 mA = **20.922** ohms = Z

2. (a) CM: 3.225v / 36.2 mA = **89.088** ohms = Z
(b) SI: 7.53v / 73.5 mA = **102.449** ohms = Z

3. (a) CM: 4.81v / 17 mA = **282.941** ohms = Z
(b) SI: 11.23v / 31.4 mA = **357.643** ohms = Z

(3) For 1300 RPM for 1100T, 2200T and 5500T coils:

1. (a) CM: 1.6v / 83 mA = **19.27** ohms = Z
(b) SI: 4.59v / 157 mA = **29.236** ohms = Z

2. (a) CM: 2.75v / 50.4 mA = **54.455** ohms = Z
(b) SI: 7.74v / 88.5 mA = **87.458** ohms = Z

3. (a) CM: 5.061v / 17.3 mA = **292.543** ohms = Z
(b) SI: 12.76v / 36.4 mA = **350.549** ohms = Z

(4) For 400 RPM for 2300T coil with 24 gauge wire and 0.5" core:

(a) CM: 0.15v / 3.7 mA = **40.541** ohms = Z
(b) SI: 2.45v / 26.2 mA = **93.511** ohms = Z

(5) For 1200 RPM for 2300T coil with 24 gauge wire and 0.5" core:

(a) CM: 0.37v / 2.7 mA = **137.037** ohms = Z
(b) SI: 4.1v / 10.3 mA = **398.058** ohms = Z

(6) For 1400 RPM for 2300T coil with 24 gauge wire and 0.5" core:

(a) CM: 0.58v / 2.4 mA = **241.667** ohms = Z
(b) SI: 8.3v / 7.8 mA = **1065.385** ohms = Z

(7) For 400 RPM for 2300T coil with 24 gauge wire and 0.75" core:

(a) CM: 0.23v / 4.2 mA = **54.762** ohms = Z
(b) SI: 0.37v / 7.2 mA = **51.389** ohms = Z

(8) For 1200 RPM for 2300T coil with 24 gauge wire and 0.75" core:

(a) CM: 0.79v / 3.4 mA = **232.353** ohms = Z
(b) SI: 0.43v / 6.9 mA = **207.246** ohms = Z

(9) For 1400 RPM for 2300T coil with 24 gauge wire and 0.75" core:

(a) CM: 0.79v / 3.21 A = **246.875** ohms = Z
(b) SI: 2.1v / 2.7 mA = **777.778** ohms = Z

(10) For 400 RPM for 6000T coil with 28 gauge wire and 0.5" core:

(a) CM: 0.49v / 2 mA = **245** ohms = Z
(b) SI: 5.48v / 0.13 mA = **421.538** ohms = Z

(11) For 1200 RPM for 6000T coil with 28 gauge wire and 0.5" core:

(a) CM: 1.25v / 1.5 mA = **833.333** ohms = Z
(b) SI: 15.04v / 4.1 mA = **3668.293** ohms = Z

(12) For 1400 RPM for 6000T coil with 28 gauge wire and 0.5" core:

(a) CM: 2.08v / 1.1 mA = **1890.909** ohms = Z
(b) SI: 18.76v / 2.5 mA = **7504** ohms = Z

(13) For 400 RPM for 6000T coil with 28 gauge wire and 0.75" core:

(a) CM: 0.64v / 1.7 mA = **376.471** ohms = Z
(b) SI: 7.97v / 7.4 mA = **1077.027** ohms = Z

(14) For 1200 RPM for 6000T coil with 28 gauge wire and 0.75" core:

(a) CM: 2.08v / 1.3 mA = **1600** ohms = Z
(b) SI: 20.4v / 5.6 mA = **3642.857** ohms = Z

(15) For 1400 RPM for 6000T coil with 28 gauge wire and 0.75" core:

(a) CM: 2.28v / 1.2 mA = **1900** ohms = Z
(b) SI: 28.4v / 2.1 mA = **13523.81** ohms = Z

It is noted that, based upon the variations of wire size, core size and number of turns, the following effects take place:
(a) the smaller the wire size the higher the gains regardless of speed;
(b) the greater the number of turns, generally the higher the gains; and
(c) the smaller the core size the higher the gains.
However, when comparing coils with smaller cores but a higher number of turns, the effects stay about the same.

Finally, the magnets are placed in the rotor so that they are all north or south poles up or out. A pure half-wave generator is created without rectifying the AC signal, which otherwise must be accomplished in a normal AC generator with electronic components in an electronic circuit.

Experimental Values for Producing Power the Conventional Way and with the Subject Invention:

The results were achieved using a small 3" magnet with a diameter of ±2" on a 1.25" high coil of 1" diameter and 3/8" centre/core of steel. (Unknown wire gauge size.)

(a) Conventional method of generating electricity:

1. 0.324 volts
2. 2.782 mA (milli-amps)
3. 0.9014 mW (milli-watts)

(b) Subject invention method of generating electricity:

1. 7.12 volts
2. 17.35 mA
3. 100.87 mW

(c) Associated gains of Volts, Current and Watts:

1. 2,198% over conventional voltage output.
2. 624% over conventional current output.
3. 13,713% over conventional power output.

The following results show the voltage, current and power outputs for an 1100, 2200 and 5500 turn coil of 20 gauge copper wire, 6" in length, 3" in diameter with a 0.75" core of steel. The results are those taken at 350 rpm, 1200 rpm and 1300 rpm.

(A) 350 RPM for an 1100 turn coil

	Volts	**mA**	**mW**
(a) Conventional method:	0.57	56.6	32.3
(b) Subject invention method:	1.14	106.6	121.5
(c) Associated gains	200%	188.3%	376.6%

(B) 350 RPM for a 2200 turn coil

	Volts	**mA**	**mW**
(a) Conventional method:	0.93	32.4	30.1
(b) Subject invention method:	2.94	70.1	206.1
(c) Associated gains	316.1%	216.4%	684%

(C) 350 RPM for a 5500 turn coil

	Volts	**mA**	**mW**
(a) Conventional method:	2.09	17.3	36.2
(b) Subject invention method:	6.11	37.9	231.6
(c) Associated gains	292.3%	219.1%	640%

(D) 1200 RPM for an 1100 turn coil

	Volts	**mA**	**mW**
(a) Conventional method:	1.45	60.2	87.3
(b) Subject invention method:	2.95	141	416
(c) Associated gains	203.4%	234.2%	476%

(E) 1200 RPM for a 2200 turn coil

	Volts	**mA**	**mW**
(a) Conventional method:	3.225	36.2	116.75
(b) Subject invention method:	7.53	73.5	553.5
(c) Associated gains	233.5%	203%	474%

(F) 1200 RPM on a 5500 turn coil

	Volts	**mA**	**mW**
(a) Conventional method:	4.81	17	81.77
(b) Subject invention method:	11.23	31.4	352.6
(c) Associated gains	235.5%	184.7%	431.3%

(G) 1300 RPM on an 1100 turn coil

	Volts	**mA**	**mW**
(a) Conventional method:	1.6	83	132.8
(b) Subject invention method:	4.59	157	704.9
(c) Associated gains	280.6%	189.2%	530.8%

(H) 1300 RPM on a 2200 turn coil

	Volts	**mA**	**mW**
(a) Conventional method:	2.75	50.5	138.9
(b) Subject invention method:	7.74	88.5	685
(c) Associated gains	281.5%	175.2%	493.3%

(I) 1300 RPM on a 5500 turn coil

	Volts	**mA**	**mW**
(a) Conventional method:	5.061	17.3	87.56
(b) Subject invention method:	12.76	36.4	464.5
(c) Associated gains	252%	210%	530%

The following readings are taken from a coil with 24 gauge wire, 0.5" centre/core of steel and 2300T.

(A) 400 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	0.15	3.7	0.56
(b) Subject invention method:	2.45	26.2	64.2
(c) Associated gains	1,633%	708%	11,563%

(B) 1200 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	0.37	2.7	1
(b) Subject invention method:	4.1	10.3	42.2
(c) Associated gains	1,108%	381%	4,227%

(C) 1400 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	0.58	2.4	1.39
(b) Subject invention method:	8.31	7.8	64.82
(c) Associated gains	1,433%	325%	4,657%

The following readings are taken from a coil made with 24 gauge wire, 0.75" centre/core of copper, 2300T.

(A) 400 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	0.23	4.2	0.97
(b) Subject invention method:	0.37	7.2	2.66
(c) Associated gains	137%	171%	235%

(B) 1200 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	0.79	3.4	2.69
(b) Subject invention method:	1.43	6.9	9.87
(c) Associated gains	181%	203%	367%

(C) 1400 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	0.79	3.2	2.53
(b) Subject invention method:	2.1	2.7	5.67
(c) Associated gains	266%	84%	224%

The following readings were taken from a coil made of 28 gauge wire, 0.5" centre/core of steel and 6000T.

(A) 400 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	0.49	2	0.98
(b) Subject invention method:	5.48	13	71.24
(c) Associated gains	1,118%	65%	7,269%

(B) 1200 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	1.25	1.5	1.88
(b) Subject invention method:	15.04	4.1	61.66
(c) Associated gains	1,203%	273%	3,289%

(C) 1400 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	2.08	1.1	2.29
(b) Subject invention method:	18.76	2.5	46.9
(c) Associated gains	902%	227%	2,050%

The following readings were taken from a coil made of 28 gauge wire, 0.75" steel centre/core and 6000T.

(A) 400 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	0.64	1.7	1.09
(b) Subject invention method:	7.97	7.4	58.98
(c) Associated gains	1,245%	435%	5,421%

(B) 1200 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	2.08	1.3	2.7
(b) Subject invention method:	20.4	5.6	114.24
(c) Associated gains	981%	431%	4,225%

(C) 1400 rpm

	Volts	**mA**	**mW**
(a) Conventional method:	2.28	1.2	2.74
(b) Subject invention method:	28.4	2.1	88.04
(c) Associated gains	1,246%	175%	2,180%

The extrapolated voltages for the items immediately above at the 1800 RPM speed for the method of the subject invention are as follows:

(A) 400-1400 RPM, 0.5" core, 2300T:
(1) 11.025v
(2) 6.15v
(3) 10.68v

(B) 400-1400 RPM, 0.75" core, 2300T:
(1) 1.665v
(2) 2.145v
(3) 2.7v

(C) 400-1400 RPM, 0.5" core, 6000T:
(1) 24.66v
(2) 22.56v
(3)24.12

(D) 400-1400 RPM, 0.75" core, 6000T:
(1) 10.25v
(2) 30.6v
(3) 36.51v

Some of the readings above do not seem consistent with others. This is attributed to the possibility that the wire connections may have been faulty or the proximity of the magnet relative to the core or coil may not have been the same. This was not taken into account at the time the tests were done.

The following figures are derived based on the premise that the subject invention has characteristics of a transformer when the number of turns on the coils change. In nearly all these situations, the subject invention acts exactly like a transformer, while the conventional way of producing electricity does not.

CM = conventional method;
SI = subject invention;

350 RPM		1100 to 2200 Turns	1100 to 5500 Turns	2200 to 5500 Turns

CLAIMS

1. A generator for providing alternating electrical current comprising:

(a) an independently supported rotating drive shaft;

(b) a plurality of spaced apart magnets extending outwardly from the shaft, the magnets each creating magnetic flux and having a polar end with a particular north or south polarity, said magnets being circumferentially spaced and mounted around the shaft, such that the polar ends of the magnets extend away from and circumferentially around the shaft;

(c) a plurality of stationary coil elements, each said coil element comprising electrical windings wound about substantially the entire coil element, each of said coil elements further comprising a solid metal core with two ends extending substantially through the coil element at the centre of the coil element, each element being positioned such that one end of each of the cores is located in spaced, adjacent relation to the magnets, whereby rotation of the shaft causes rotation of the magnets around the shaft and in spaced, adjacent relation to the cores of the coil elements, the magnetic flux of the magnetics cutting the cores of the coil elements, creating alternating current in the coil elements; and

(d) a first housing in which some of the plurality of coil elements are mounted and a second housing in which the remainder of the plurality of coil elements are mounted.

2. The generator as in claim 1 wherein the magnets are spaced 90° apart around the shaft.

3. The generator as in claim 1 wherein magnets with north polar ends alternate with the magnets with south polar ends in spaced, circumferential relation around the shaft.

4. The generator as in claim 1 wherein all the plurality of magnets are magnets with the same polar ends.

5. The generator as in claim 1 wherein the magnets are equidistantly spaced around the shaft.

6. The generator as in claim 1 wherein the plurality of magnets is rotated by the drive shaft between and in spaced apart relation with the housings.

7. The generator as in claim 1 further comprising four magnets extending from the shaft, adjacent magnets being positioned perpendicular to each other, each magnet having either an outwardly extending north or south polar end, and said magnets being positioned such that a north polar end magnet follows a south polar end magnet, in spaced, circumferential relation around the shaft.

8. The generator as in claim 1 further comprising multiple north polar end magnets and multiple south polar end magnets extending from the shaft, said magnets being positioned in spaced, circumferentially relation around the shaft.

9. The generator as in claim 1 in which the shaft is positioned within a rotor and the magnets are circumferentially mounted on the rotor.

10. The generator as in claim 1 in which the shaft is connected to power means for rotating the shaft, whereby upon rotation of the shaft, the magnets are rotated around the shaft in spaced relation to the cores of the coil elements, thereby inducing an alternating electrical field along the length of each of the cores, thereby producing an alternating electric current in the windings of the coil elements.

11. The generator as in claim 10 further comprising means to transmit the alternating electrical current for electrical power usage.

GEOFFREY SPENCE: ENERGY CONVERSION SYSTEM

US Patent 4,772,816 20th September 1988 Inventor: Geoffrey M. Spence

ENERGY CONVERSION SYSTEM

This is a slightly reworded excerpt from this patent which has a substantial electrical output capable of providing it's own electrical input to be self-powering as well as generating kilowatts of excess power. The highly-respected Dr. Harold Aspden comments:

"In my Energy Science Report No. 8I, I also mentioned the apparatus designed by Geoffrey Spence, an inventor based in U.K. This is the subject of his U.S. Patent No. 4,772,816. Electrons injected into a chamber formed between two concentric electrodes are deflected into the inner electrode by a pair of magnets that provide a magnetic field along the central axis of the concentric electrodes. Of itself, this should add no excess energy, because the energy fed into accelerating the electrons is merely absorbed by electrostatic repulsion in charging the central electrode and so the capacitor. However, if that electron flow pulsates and there are connections to draw electron current from that central electrode then the pulsation implies a recurring sequence of charge and discharge. That 'magic capacitor' function is then harnessed.

The questions then are whether the Spence invention really works and whether it is commercially viable? Well, I wrote that Energy Science Report back in 1996, six years ago, and it is only a few months ago that I heard any more of that project. Geoffrey Spence has developed the prototype product to the stage where he has closed the loop in the sense that a portion of the output power was fed back to impart the energy needed to sustain the electron beams. He has a self-sustaining unit that can deliver kilowatts of useful electrical power with no visible energy input."

ABSTRACT

The apparatus uses a magnetic field (**80**) to accelerate a charged particle radially towards a target electrode (**10**). The increased kinetic energy of the particles enables the particle to give up more electrical energy to the target electrode (**10**) than was initially given to it. This charges the target electrode (**10**), and the increased energy is extracted from the apparatus by connecting an electrical load between the target electrode and a point of lower or higher potential.

DESCRIPTION

This invention relates to a process and apparatus for generating a potential difference between two or more electrodes and using charged particles as energy carriers.

Electrical power is usually generated by burning a fossil fuel and converting the energy released into rotary motion which drives electrical generators. This is cost-effective only if carried out on a large scale, the conversion process being inefficient; utilising natural resources, and producing waste products which can cause serious environmental pollution. An additional disadvantage is that the electrical power cannot be supplied directly to road vehicles or ships.

The energy-conversion process of this invention involves no health or pollution hazard and generates electrical power directly by a single-stage process without waste products. The overall energy-conversion factor and power-to-weight ratio are both high, making the apparatus suitable for most fixed and mobile applications.

One known apparatus for doing useful work by operating on electrons with a magnetic field is called the "betatron". This includes a doughnut-shaped vacuum chamber between the poles of a specially-shaped electromagnet. Thermionically-produced electrons are injected into the chamber with an initial electrostatic energy of about 50 keV. As the magnetic field builds up during its positive-going half-cycle, it induces an electromotive force within the doughnut, which force accelerates the electrons and forces them to move in an curved path, by interaction with the magnetic field. An important distinction between the betatron and the energy converter of this invention is that in the former the magnetic field has got to be able to increase over a very short period, in order to accelerate the electrons sufficiently, whereas in the latter the magnetic field is virtually constant and the electrons fall inwardly to give up both their kinetic energy and electric charge to a central electrode.

The present invention aims at providing an energy converter which may be mobile and which has a permanent magnet or an energised source of magnetic radiation associated with it in order to amplify the electrical energy initially imparted to charge particles fed to, or produced in, a so-called "vacuum" chamber forming part of the generator, which increased energy is extracted from the target electrode on which the particles are incident.

Accordingly the present invention provides an energy converter as per the appended claims.

While the invention is not to be limited to any particular theory of operation, it is based on the fact that, when a charged particle is constrained to move through a radial distance d (irrespective of the path which it actually follows) through a magnetic field of intensity $\mathbf{H}$, the work done on the particle is $\mathbf{H} \times \mathbf{d}$. For an electron carrying a charge $\mathbf{e}$, and moving at a speed $\mathbf{v}$ over distance $\mathbf{d}$, the total force on the electron is the centripetal force the sum of $\mathbf{H} \times \mathbf{e} \times \mathbf{v}$, less the force exerted on the electron in the opposite direction by the centrifugal force, which is the sum of $(\mathbf{m} \times \mathbf{v}^2)/\mathbf{r}$. By making the radius of the centre electrode appreciably greater than the orbit of equilibrium, the centrifugal force can be minimised, thus maximising the centripetal force, and hence the work done in bringing the charge to the electrode.

The process by which the converter of this invention works uses, as a source of charge, electrically-charged particles, for example electrons and/or ions. Two or more electrodes are housed in a low-pressure chamber. A magnetic field as specified below traverses the chamber: it emanates from a permanent magnet, electromagnet or a source of magnetic radiation. An external source of energy is used to give the charge particles initial kinetic energy, for example by heating, acceleration through an electric field, or from nuclear radiation. The energy-conversion process uses the magnetic field to transfer the charged particles along a desired orbit until they impinge on a central electrode (cathode). The work done on the particles (therefore the electrical potential attained by the cathode) is proportional to the resultant magnetic force times the distance over which the force acts. As the particles move within the chamber they cross the magnetic field. This produces a force acting on the particles, the force being proportional to the field strength, speed and electrical charge of the particles, and the sine of the angle of incidence between the path of the particle and the magnetic lines of force. This force has an angular component and a centripetal one, which forces the particles to travel along a spiral orbit.

An opposing centrifugal force also acts on the particles in opposition to the centripetal magnetic force. The electrode potential is proportional to the work required to be done on the charged particles to overcome both the centrifugal force and the electric field around the cathode as the charges accumulate and the potential difference between the electrodes increases. Maximum electrode potential is reached when the centrifugal and repulsive forces are equal to the centripetal force, after which no further charged particles reach the electrode. The radius of the electrode determines the minimal value voltage between the central and an outer electrode: as the central electrode radius is reduced (by sputtering or erosion) the centrifugal force increases, reducing the number of charged particles which can reach the central electrode and therefore the electrode potential, for a given field strength and particle speed. The difference in mass between ions and lighter charged particles, such as electrons, results in different centrifugal forces for given particle kinetic energies. The generator output and efficiency are optimised when the generator uses the maximum magnetic field to minimise the centrifugal force and to maximise the radial distance over which the force acts for a given field strength. Particles having the highest charge-to-mass ratio should be used.

Low pressure gases can be used as a charge source when ionised by particle collision and excitation within the chamber. Doped gases can minimise the energy level for ionising gas atoms/molecules thereby improving efficiency. However, the resultant magnetic force is lower for the heavier ions due to their lower velocity so that the electric field radiated by the high voltage electrode (cathode) can attract oppositely charged particles (+ ions) and subsequently discharge the electrode reducing the output voltage. Various methods can be used to overcome or reduce this effect. For example one method would be to separate the opposite charges and/or to use electrical biased grids to control the flow of opposite charges to the high voltage electrode.

Gaseous systems are generally more complex than single charge systems, providing higher currents at lower voltages, whereas single charge systems, for example electrons used in high vacuum chambers, can generate higher voltages.

The magnetic field can be from one or more permanent magnets and/or from one or more electromagnets; a static magnetic field produces a constant output voltage, while a varying field produces a varying voltage for particles with equal mass and velocity.

An external source is used to accelerate the charged particles to give them initial kinetic energy, which is released as heat when the particles collide with the electrode. When the energy represented by the increased voltage between the electrodes is greater than the energy required to provide the charged particles; and accelerate them, the conversion process is self-sustaining, the output energy being the difference between the sum of the kinetic energy lost and the energy generated. Charge flows from the central electrode via an external load to another electrode. The electrical energy (work) released is a function of the current (sum of charges that flow per second) times the potential difference. Electrical and thermal output can be controlled by varying: the field strength; the particle speed; the particle density (mean free path), and/or by incorporating a grid to control the rate at which particles reach the central electrode. The output is also proportional to the heat lost or gained, since the translational energy of the particle is proportional to its temperature. Heat liberated at the electrode can be returned to the particles to maintain their energy, or be utilised in a heat exchanger for external use. The generator normally uses non-reacting conductive material to prevent chemical reaction by gases, coolants etc. with the electrodes, container walls or other components. Various particle trajectories, directional movements and positioning of the orbiting particles can be used with appropriate magnetic fields. The low-pressure gas can be ionised by any suitable means: one method would be to use an electron/ion gun where the plane and direction of the injected particles is correct for the applied magnetic field. In gas apparatus, the electrons flowing through the external circuit, on reaching the anode, recombine with a gaseous ion to form a neutral gas atom/molecule. This atomic particle is duly re-ionised by collision and/or the electric fields, the energy being directly or indirectly derived from the work done by the resultant force acting on the charged particles.

In order that the invention may be better understood, it will now be described with reference to the accompanying schematic drawings, which are given by way of example, and in which:

Fig.9 is a scheme of a two-stage converter, using both forms of charged particles concurrently.

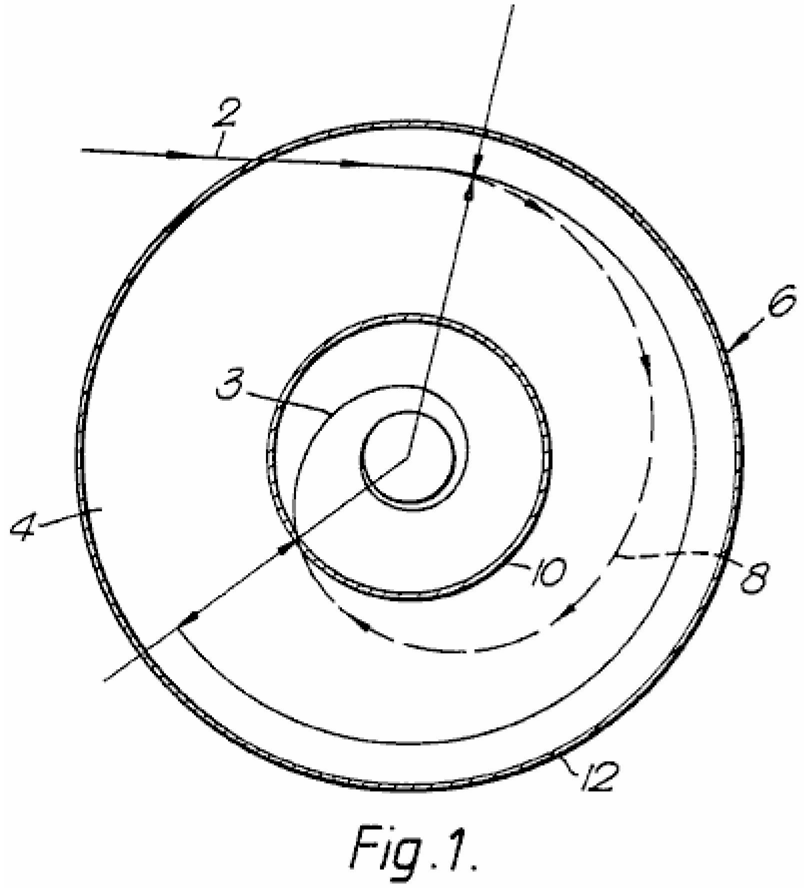

Fig.1.

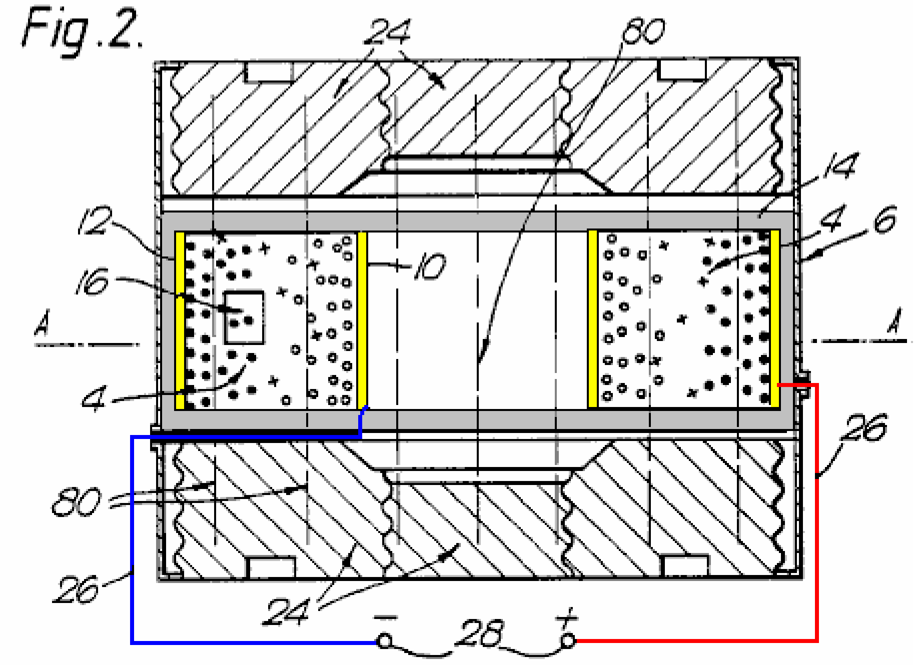
As shown in **Fig.1**, a charged particle is injected along a trajectory **2** into a magnetic field extending normal to the plane of the drawing. The field permeates the space **4** of the annular cross-section within a cylindrical chamber **6**. The magnetic field produces a force on the particle, extending at right angles to both it's direction of motion and the magnetic field. The resultant centripetal force causes the particle to follow a spiral path **8** ending on the central electrode **10** spaced radially inwards from the outer cylindrical electrode **12**. The extra energy acquired by the particle is a function of the radial distance travelled and the strength of the magnetic field between the electrodes. This energy is given up on impact with the central electrode, in the form of heat and/or work done in bringing the charge against the opposing electric field to the electrode. In the absence of the central electrode **10**, the electrons would follow the orbit of equilibrium **3**, this being the orbit followed by a particle when the centrifugal and centripetal forces balance, resulting in no work being done on the particle.

Fig.2.



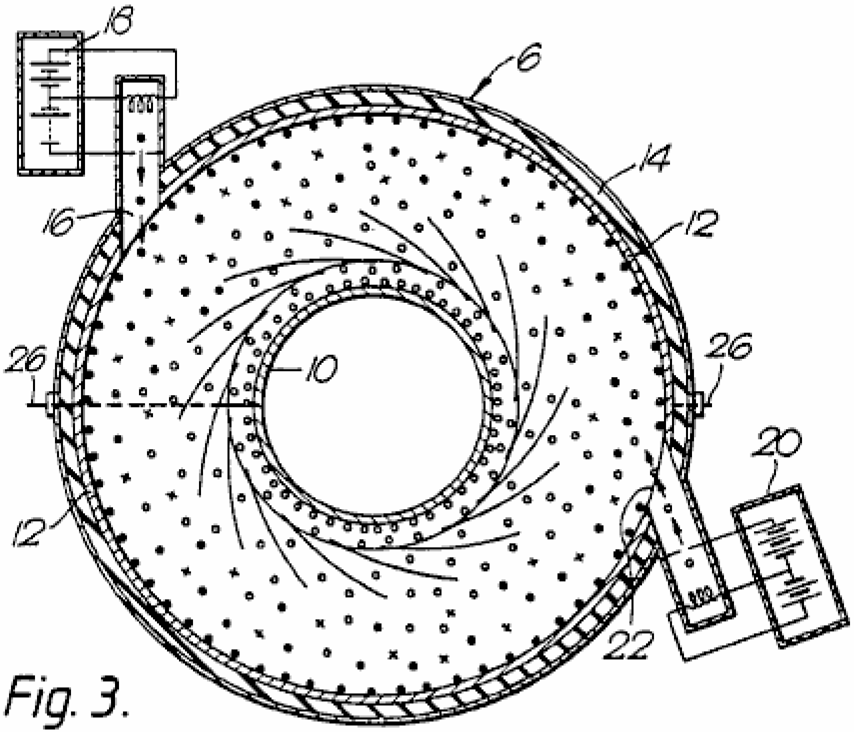


Fig. 3.

As shown more particularly in **Fig.2** and **Fig.3**, the energy converter **1** consists basically of a annular chamber **6** having an outer cylindrical electrode **12**; an inner cylindrical electrode **10**, and two gas-tight walls **14** of electrical insulation material. In the electrode **12** is a port **22** through which an electron gun **20** can inject electrons into space **4**. Additionally or alternatively, an ion gun **18** can inject positively-charged particles through port **16**.

Seated on the major flat surfaces of chamber **6** are magnetic pole-pieces **24** giving rise to a uniform magnetic field **80** which traverses the space **4** parallel with the axis of chamber **6**. The magnets may be ceramic permanent magnets, or they may be electromagnets. In either case, means (not shown) may be provided for adjusting the magnetic field strength.

Heavy conductors **26** connect the two electrodes to terminals **28** across which a resistive load can be placed to dissipate the generator output.

A vacuum pump (not shown) has its inlet in communication with the interior of chamber **6** so that the gas pressure in the generator can be reduced to, and kept at, a desired sub-atmospheric value. Associated with the pump, or separate from it, may be means for ensuring that the gas in the generator is of a desired composition, for instance, one which enhances the possibility of ionising collisions between the charged particles and gas atoms or molecules. One such suitable gas would be neon containing 0.1% argon by volume.

In order to cause the generator to start working, it is necessary to start the vacuum pump and to energise the electron gun or each particle source. The latter involves heating a filament from an external source of power until the required internal energy level (temperature) is reached which in turn causes a piece of thermo-emissive material to emit electrons. If the electrons are to be the charge carriers, they are accelerated by a suitable electric field and projected into the space **4**. Here they are further accelerated by the radial electric field between the electrodes, and at the same time have a deflecting force applied to them by the axial magnetic field through which they pass.

For an ion source, the electrons are accelerated until they impact some atoms or molecules, to produce a stream of ions which likewise pass into the space **4**. With the polarities shown, the electrons are attracted to the central electrode, while the ions are pulled towards the outer electrode, which accounts for the different orientations of sources **18** and **20**.

Any gas molecules which pass close to, or between, the electrodes are ionised by collision and/or the electrostatic field. Output current can then be taken through a load impedance connected across terminals **28**. The impedance is matched to prevent the internal process energy dropping below a value which would prevent the re-ionisation of the gaseous atoms. As each ion is deionised at the anode, the gas atoms will tend to continue to circulate until re-ionised, the resultant force drawing both the ions (shown by solid circles) and electrons (shown by hollow circles) back into their respective orbits.

It is envisaged that, in the case of a converter using electrons, the chamber could be evacuated to a chosen sub-atmospheric pressure and sealed.

In that form of the invention shown in **Fig.4**, each electron source forming one of a circular series **29** of sources has a body **30** of electro-emissive material, such as molybdenum coated by caesium, heated by an electric filament **32** connected in series or parallel across a source of electric power (not shown). Immediately in front of each emitter **30** is a grid **34** of fine wires, all the grids being connected with a source of adjustable voltage so as to control the flow of electrons from the emitter. These electrons are projected through one or more acceleration electrodes **36** across which a potential difference is established along the electron path, so that each incremental electron source injects a stream of electrons having known kinetic energy into a space **38**, indicated by the circle shown in a broken line, traversed by the deflection magnetic field, within which is the central, target, electrode **40**. The stream of electrons injected into the magnetic field may be focused by electric and/or magnetic fields.

In the remaining Figs, those parts already referred to will retain the same references.

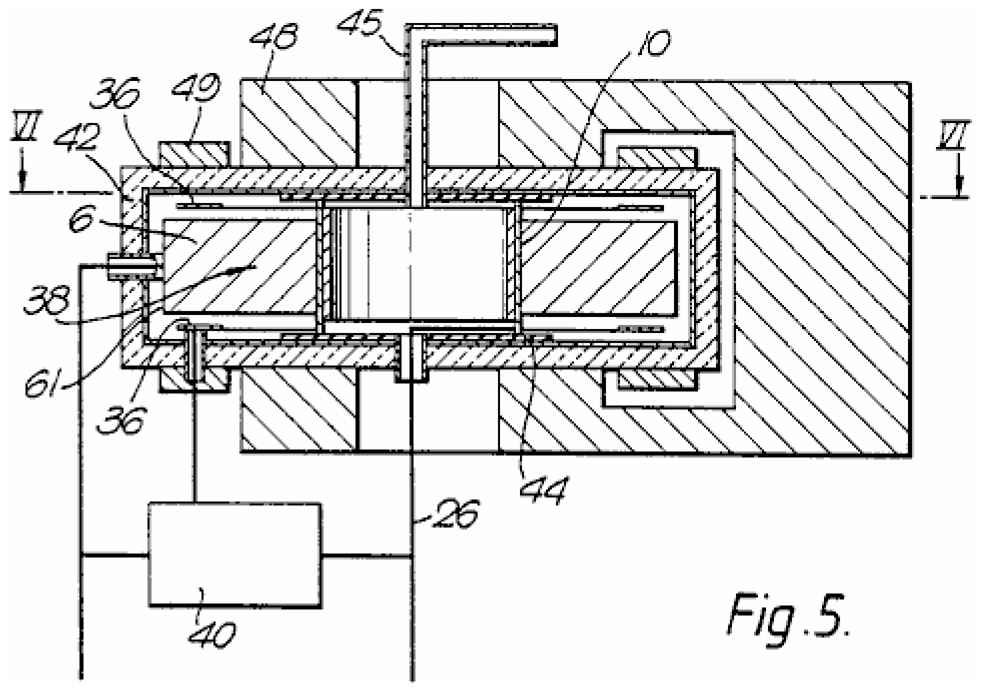

Fig.5.

In the "flat disc" configuration shown in **Fig.5**, the annular chamber **6** is enclosed in a body **42** of thermal insulation material. The central electrode **10** is seated on insulators **44** which are pierced by conduits **45** for the passage of a coolant fluid and by an output lead **26**, which may extend along the conduit so that it too is cooled.

Fig.5 shows how the deflection magnet is generally U-shaped, and has two annular pole-pieces **48**, so that the magnetic field is uniform between the surface of electrode **10** and the region **38** radially innermost of the circular electron source, the electric field between the electrode **36** and emission surface **61** providing the electrons initial accelerations (kinetic energy). **Fig.5** also shows how a voltage is tapped off the resistive load **40** (which thus functions as a potentiometer) and is fed through to the acceleration electrode **36**.

Chamber **6** is also provided with two annular magnets **49** (or a circular series of incremental magnets) designed to influence the direction along which the electrons pass into space **38**. The magnets provide local magnetic fields to ensure that the electrons meet the boundary of space **38** tangentially, i.e. with zero radial velocity.

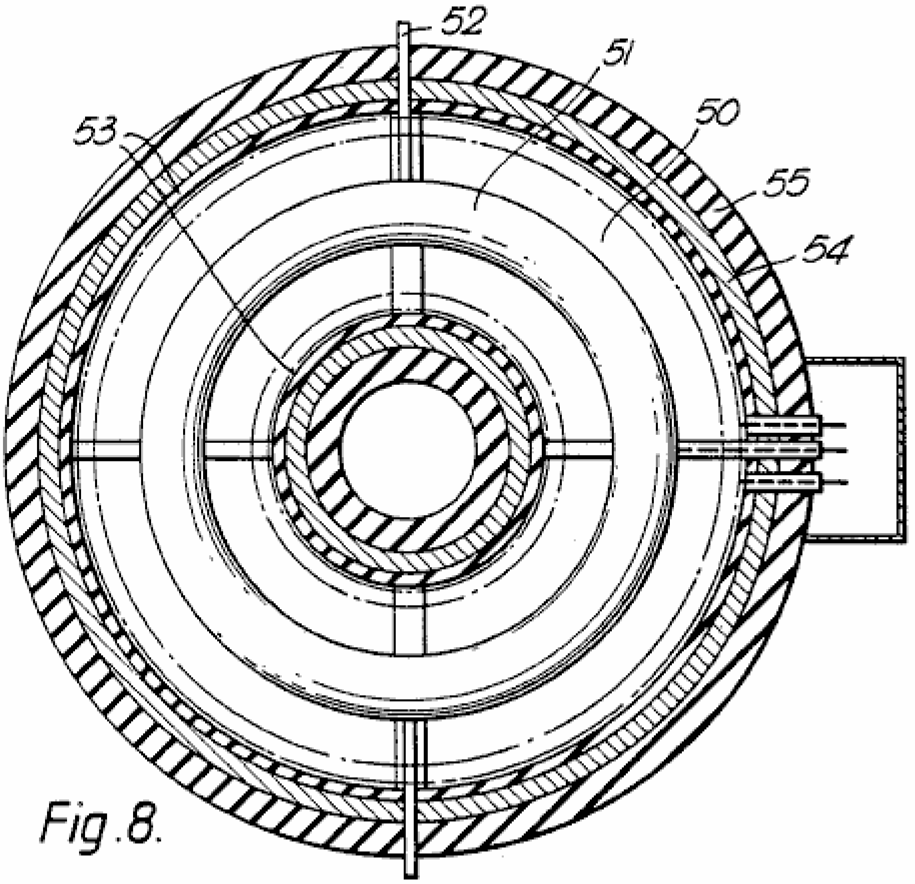

Fig.8.

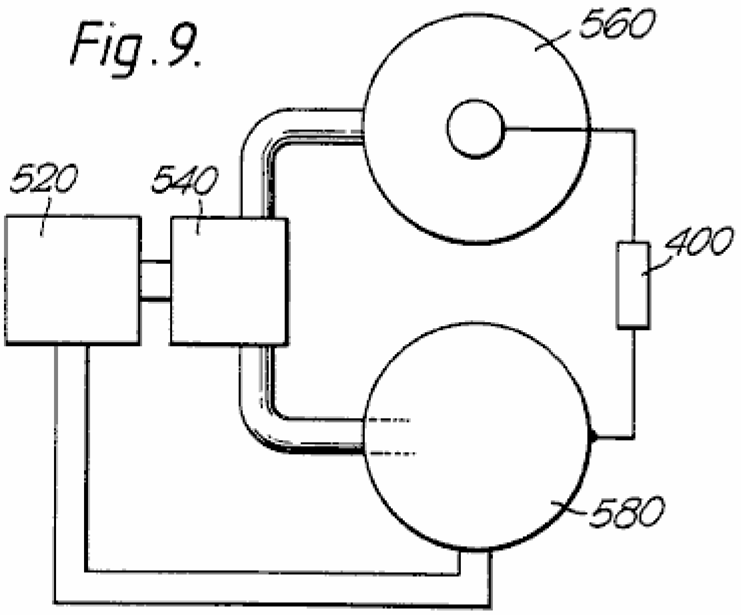
In that form of the invention shown in **Fig.7** and **Fig.8**, the individual "flat disc" converters of **Fig.5** and **Fig.6** are arranged in a type of "circular" construction, such that the magnetic fields extend along the axis of the resulting toroidal space **50** penetrated by a single toroidal target electrode **51** through which a coolant fluid may pass, along conduits **52**. The cross-section of **Fig.8** shows that the magnetic fields are supplemented by an electric field produced by windings **53** wound on a magnetic core **54** bounded by insulation **55**.

Apart from the fact that the electrodes are common to all converters, each functions individually as described above. Obviously the power source driving the heaters for the electron guns **56**; the electromagnets (if any); the acceleration electrodes and the control grids, have to be of sufficient capacity to supply the greater power needed to drive this "toroidal" configuration. Some changes would need to be made to the physical dimensioning and positioning of the relatively-complex construction, but as all these are readily understood by a competent engineer, they are not further described in this specification.

Fig.9.



As already mentioned, the converters of this invention are of two types, i.e. electronic and ionic. **Fig.9** shows diagrammatically how they may be combined to take advantage of their differences. In the two-stage power generation apparatus shown in **Fig.9** the first stage consists of an ioniser **520** supplying a mixture of charged particles, i.e. ions and electrons, to a separator **540**, which supplies electrons to a second stage consisting of a sealed electronic converter **560** in parallel with a gaseous ionic converter **580**.

The separator **540** may use the different particle masses to separate them centrifugally using, for example, the energy conversion system of **Fig.1** (without the target electrode), or it may use electromagnetic deflection fields, or a physical diffusion process, either alone or in combination. As this is not part of the subject-matter of this invention, it will not be described herein in any further detail.

In the generators of **Fig.6** and **Fig.8**, the respective particles are deflected magnetically and accelerated radially, to function as already described above.

Because each generator is designed to operate most effectively with its particular form of charge carrier, it can be designed optimally, thus reducing the energy absorption caused by ions and electrons recombining before each has fallen on its respective target electrode. Because the electronic converter would finish up with a negatively-charged electrode, whereas the converse is true for the ionic converter, the load **400** extracting energy from the apparatus is connected across the two target electrodes. The other two electrodes of the converters may be held at the same potential, as by being connected together, or their potentials may float.

The generator can be designed to produce a wide range of output voltages and currents. The lower-energy generators are light enough to be mobile, so that they can power vehicles or act as stand-by generators. Various electrode and magnet configurations can be used, and the generators can be connected in series or parallel. Cooling jackets are fitted to prevent overheating in high-powered apparatus, and the generator is enclosed within a thermally-insulating jacket to reduce heat losses thereby increasing particle velocities. For high-energy generators, it may be necessary to provide for forced cooling of the inner electrode, as by fins projecting therefrom into a high-speed stream of suitable coolant.

Although the process according to this invention is particularly suited to using external electrical energy, it must be understood that other sources can be used to provide the initial energy input, e.g. solar and waste process heat are some of the varied energy sources which could be utilised. Control of the charge-generation process can be achieved by other means, including one or more electrically-biased grids, as used in thermionic valves.

CLAIMS

1. An energy conversion process for generating an electric potential, the process comprising; providing a source of electric charge carriers of predetermined polarity, accelerating the carriers away from the source, introducing the carriers into a magnetic field transverse to the path of the carriers in a process chamber, the field bounding an inner electrode within the chamber such that the carriers orbit the electrode while accelerating radially toward the electrode; and converting the resulting increased kinetic energy of the carriers

into an electric potential at the electrode before the carriers reach an orbit of equilibrium in which the centripetal force is balanced by the centrifugal force on the carriers.

2. A process according to claim 1 in which the electric potential is created between the inner electrode and an outer electrode radially spaced from the inner electrode.

3. A process according to claim 2 in which the outer electrode provides the said source of the charge carriers.

4. A process according to claim 1 or claim 2 in which the chamber is maintained at a sub-atmospheric pressure.

5. A process according to claim 1 in which the electric potential drives a load connected between the inner electrode and a point remote from the electrode.

6. A process according to claim 1 or claim 2 in which the electric charge carriers comprise electrons or ions.

7. A process according to claim 1 in which further charge carriers of the opposite polarity traverse the magnetic field and accumulate at a second electrode to increase the potential difference between the two electrodes.

8. A process according to claim 1 in which electrically biased grids control the flow of the charge carriers from the source.

9. A process according to claim 1 in which the charge carriers are separated from charge carriers of the opposite polarity before being introduced into the magnetic field.

10. A process according to claim 9 in which the charge carriers of opposite polarity are introduced into a corresponding second magnetic field, whereby a potential difference is produced between respective electrodes in each field.

11. A process according to claim 1 in which the carriers are injected into the magnetic field.

12. A process according to claim 11 in which the injection energy is produced by accelerating the carriers through an electric field.

13. A process according to claim 11 in which the injection energy is produced by accelerating the carriers through a magnetic field.

14. A process according to claim 1 in which the injection energy of the carriers is produced by nuclear emission.

15. A process according to claim 1 in which the injection energy of the carriers is produced by heat.

16. A process according to claim 1 in which the generated electric potential is directly or indirectly used to maintain the generation of charge carriers or the internal temperature of the space traversed by the magnetic field, or the applied magnetic field.

17. A process according to claim 1 in which the generated electric potential is directly or indirectly used to maintain the generation of charge carriers and the internal temperature of the space traversed by the magnetic field and the applied magnetic field.

18. An energy converter including a source of electric charge carriers of a predetermined polarity, a process chamber having an inner electrode, means for accelerating the carriers away from the source and for introducing the carriers into the chamber, means for applying a magnetic field transverse to the path of the carriers and bounding the inner electrode of the chamber such that the carriers orbit the electrode while accelerating radially toward the electrode, the electrode being located at a radius which exceeds the equilibrium radius for the carrier mean velocity and applied field strength and intercepting the carriers such that the increased kinetic energy of the carriers due to centripetal acceleration is converted to an electric potential at the electrode.

19. An energy converter according to claim 18 in which the chamber includes an outer electrode spaced radially from the inner electrode, and means for injecting the charge carriers into the space between the electrodes.

20. An energy converter according to claim 19 in which the outer electrode provides the said source of charge carriers.

21. An energy converter according to claim 19 further comprising an insulating wall bounding the outer electrode.

22. A converter according to claim 18 further comprising means for maintaining the chamber at a predetermined sub-atmospheric pressure.

23. A converter according to claim 19 in which the outer electrode has at least one port through which the charge carriers can be injected into the chamber along a desired trajectory.

24. A converter according to claim 23 in which the outer electrode has plural ports and each port communicates with a thermionic source of the respective carriers.

25. A converter according to claim 18 in which the chamber is a vacuum chamber.

26. A converter according to claim 18 further comprising electrically biased grids for controlling the flow of charge carriers from the source.

27. A converter according to claim 22 or claim 25 in which the evacuated chamber comprises a sealed unit.

28. A converter according to claim 18 further comprising means for adjusting the strength of the applied magnetic field.

29. A converter according to claim 18 in which the chamber is filled with low pressure gas.

ROBERT ALEXANDER: INCREASING ELECTRICAL POWER

US Patent 3,913,004 14th October 1975 Inventor: Robert W. Alexander

METHOD AND APPARATUS FOR INCREASING ELECTRICAL POWER

This patent shows a method of altering a standard electrical generator intended to be driven by a separate motor, so that it operates without the motor. In an example quoted, a DC input of 48 volts at 25 amps of current (1.2 kW) produces a 110 volt 60Hz AC output of 3.52 kW. That is a Coefficient Of Performance of 2.93 at an output level suited to Off-The-Grid operation of a house.

ABSTRACT

A form of rotating machine arranged in such a way as to convert a substantially constant input voltage into a substantially constant output voltage; involving generally, a rotor that revolves at a substantially constant speed within a stator, and which comprises a transformer core subjected to and having a primary motor-transformer winding and a secondary transformer-generator winding; whereby transformed and generated power are synchronously combined as increased output power.

BACKGROUND

Electrical power is frequently changed in voltage, phase, frequency, and the current is changed from alternating to direct or from direct to alternating. Voltage conversion in AC circuits is usually by means of transformers, and in DC circuits is usually by means of motor-generators. Phase conversion is also accomplished by either transformers or motor-generators, and frequency conversion is most simply done by motor-generators.

Motor-generators have various classifications of use, as follows:

(1) DC to DC, used to charge batteries and to boost voltage.
(2) AC to AC, used for frequency and phase conversion
(3) AC to DC used for all types of service, such as battery charging, generator and motor field excitation, railways, electrolysis, and speed control etc. and
(4) DC to AC used to limited extent for special applications.

To these ends combination motor-generators have been built, such as dynamotors stepping up DC voltage for radio equipment and amplidynes for reproducing a weak signal at a higher power level. When a particular variable frequency A.C. is required of a motor-generator set and the power supply is DC, the equipment will include a DC motor for variable speed and a separate alternator driven by it. Such equipment is special in nature and characterised by separation of the motor and generator and by polyphase (usually three-phase) generator windings and with auto transformers having suitable taps for obtaining the required voltages; and a DC speed controller for the motor. The phase output of such equipment is selective and its single phase capacity necessarily restricted (66%) as compared with its three-phase capacity, in which case transmission efficiency for single phase is poor.

When a higher level power output is desired, the amplidyne is employed with field windings and brushes equipped for the purpose, and in some instances to give a constant current output from a constant voltage input, for example, in inverted rotary converter provided to convert DC to A.C. However, the present invention is concerned with method and apparatus for increasing electrical power and provides a dynamo-electric converter that operates from an electrical energy supply to produce A.C. most efficiently for a useful load.

The method involves simultaneous motor-transformer-generator steps and the preferred embodiment of the apparatus involves a dynamo-electric converter (DEC) in the form of a rotary machine combined in a single rotor revolving within a stator, the rotor being comprised of a transformer core having both a primary motor-transformer winding and a secondary transformer-generator winding, and the stator being comprised of magnetic field poles.

Synchronous converters have been combined in single rotor machines to produce DC from A.C., but that effect is quite different from the effect of the present invention when A.C. is to be produced from DC in a single rotor having primary and secondary armature windings as distinguished from armature windings common to both A.C. and DC circuits. With the present invention, both a transforming and a generating effect are produced in the rotor, all of which is inherently synchronised and delivered through the A.C. outlet leads. A.C. motors and DC generators have been combined in one machine, that is in one rotor, and referred to as synchronous converters.

However, synchronous converters are lacking in their ability to change DC into A.C. when operating from the former as a prime mover to drive a generator simultaneously, and more specifically to drive an alternator synchronously.

SUMMARY OF INVENTION

This method involves the placement of a primary winding in a field to both motor the same and to have a transformer effect with respect to a secondary winding also in a field to have a generator effect. In its preferred embodiment, this dynamo-electric converter is comprised of primary and secondary windings combined in a rotor commutated to alternate a DC energy supply in and thereby motivate the rotor within a stator field. The primary winding is advantageously of fewer turns than the secondary and by means of electromotive force drives the secondary windings of more turns to cut the magnetic lines of force for the generation of electrical energy at a higher voltage level than the DC supply. This DC operated motor is shunt wound with the stator field poles fully energised by the DC energy supply, or is provided with permanent magnet field poles, to efficiently motivate the rotor and efficiently generate electrical energy in the secondary windings. The A.C. output of the secondary windings is inherently synchronised with the transformer function of the primary windings combined in the common slots of the single rotor; and by adding the transformer and generator voltages and amperages the wattage is correspondingly increased at the output.

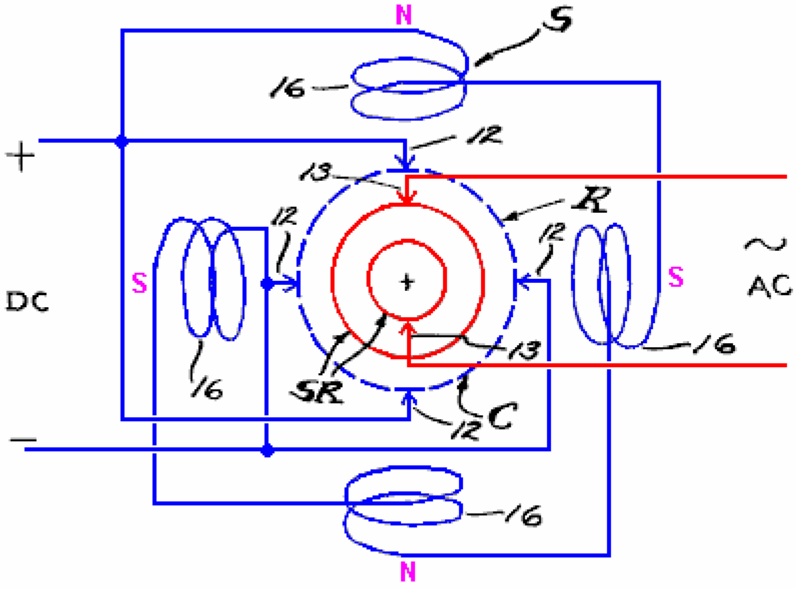
PREFERRED EMBODIMENT



The dynamo-electric converter is illustrated diagrammatically in the drawings and involves, generally, a rotor **R** carried upon spaced bearings **B** so as to rotate on an axis **A** concentric within a stator **S**. The rotor **R** comprises the armature, while the stator **S** comprises the field, there being a commutator **C** associated with primary windings **10** on the rotor and slip rings **SR** associated with secondary windings **11** on the rotor. Brushes **12** and **13** are engaged slideably with the commutator and slip rings respectively, by conventional means, to conduct DC through the commutator **C** and to conduct AC through the slip rings **SR**. The brushes **12** and interconnected primary windings **10** comprise a motor while the brushes **13** and interconnected secondary windings **11** comprise a generator or alternator.

In practice, the field windings **16** can be separately energised or connected in parallel with the brushes **12** or shunted with respect to the primary motor winding **10**. Motorisation of the armature rotor **R**, or motoring thereof, causes continued polarity reversals on a cycle basis as determined by the speed of rotation, and this of course results in magnetic reversals in the rotor core **15** and a consequent induction in the secondary windings **11**. A feature of this invention is the combining and co-operative relationship of the primary and secondary windings which occupy common slots in and embrace a common portion of the core **15** of the rotor **R**, thereby to have a transformer function as well as a generator function as the lines of magnetic force are cut by the secondary windings. The stator **S** has field poles of opposite magnetic polarity, excited independently from the armature, or as permanent magnets, and preferably shunted across the DC input. As shown, there are four equally spaced field poles in a circumferentially disposed series.

In practice, the primary DC motor windings are of fewer turns in the rotor slots than the secondary AC generator windings. For example, the primary motor windings **10** are flat wound between north to south poles of the field while the secondary generator windings are flat wound in the same or common slots of the rotor armature. In a typical unit having a four brush commutator with 20 bars and having a 20-slot armature, the primary windings **10** are comprised of a number of turns of conductor efficiently to draw 48 volts DC at 25 amperes or 1,200 watts to rotate at 1,750 rpm, while the secondary windings **11** are comprised of a number of turns of conductor efficiently to deliver 60 cycle (by transforming and generating) 110 volts AC at 32 amperes or 3,520 watts, the volt meter used to read these values upon an actual reduction to practice being calibrated to read the root-mean-square (RMS) value of the pure sine wave, which is 70.7% of the peak voltage.

The reduction to practice previously referred to as a "typical unit" was constructed of a machine originally designed as a self-exciting 60 cps 110 volt 2.5 kVA generator to be shaft driven by a separate prime mover. Firstly, the prime mover was eliminated. The exciter windings were intended to excite the field at 45 volts DC delivered through the commutator, while the generator windings were intended to independently deliver 110-120 volts AC through the slip rings. The winding ratio between the exciter and generator windings was approximately one to three, and these are the values which determined the values employed in the present reduction to practice. However, it is to be understood that other values can be employed by design, for operation at the desired input and output voltages and amperages. It is also to be understood that the example reduction to practice disclosed herein is not necessarily the optimum design, in that other input-output power balances are contemplated, such as a DC battery input voltage substantially equal to the AC power voltage. In any case, an unexpected increase in power is realised by practising this invention.

This dynamo electric converter inherently operates at a substantially constant angular velocity with the result that the alternating cycles of the output are substantially constant. Also, the DC input voltage can be maintained at a substantially constant level with the result that the AC output voltage is also substantially constant. As shown, the output is single phase AC in which case the effective power in watts delivered is the product of current, voltage and power factor. Since the voltage is substantially constant, the current varies with load applied to the output as it is affected by the power factor. It will be seen therefore, that the apparent power represented by voltage times amperage is drawn directly from the DC input and applied to the primary motor winding **10** to motivate the rotor **R** for the functions previously described. It will also be seen therefore, that the DC input is commutated into AC and transformed by induction from windings **10** into windings **11**.

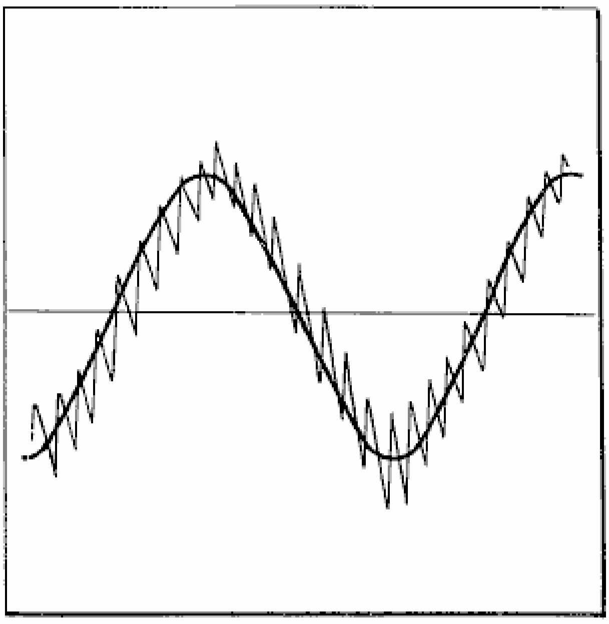
It will also be seen therefore, that the AC generated by motorisation of the motor is synchronously imposed upon the windings **11**, and all to the end that the two alternating currents are complementary and one added to the other. It will be observed that the output wattage is approximately triple the input wattage, by virtue of the synchronous superimposing of transformed input voltage and generated voltage while utilising the former to operate the rotor in order to generate the latter. A feature of this invention is the separation of the primary and secondary circuits and the consequent isolation of the inverted input DC from the outlet AC and the utilisation of input energy commensurate with output load according to amperage required for the operations to which this DEC machine is applied.

In carrying out this invention, the dynamo electric machine is conventional in design and the primary and secondary windings **10-11** are wound into the common slots of the armature as they are in self exciting generators. However, the primary windings **10** are motor-transformer windings and function totally as such. Similarly, the secondary windings **11** are wound into the armature slots together with the primary windings **10** and are powered with current that is alternated by virtue of the commutation and rotation of the armature, and consequently there is a transformer action between the primary windings **10** and secondary windings **11**, and this transformer function is supplemented by generation of a superimposed current by virtue of the secondary windings **11** cutting the magnetic lines of force provided by the surrounding stator field. Consequently, there is a multiplying of power synchronously applied through the slip rings **SR** to the output brushes **13**, and this increased output power is measurable as previously described and double or almost triple that of the input power.

METHOD

Referring now to this method of increasing electrical power, input alternating current is applied to a primary winding to both motor and alternately magnetise a core. The said primary winding is immersed in a field and consequently is caused to motor and simultaneously to perform the first stage of transforming. A second stage of transforming is then performed by a secondary winding associated with the core to function as both a transformer and a generator winding, and the output current is drawn from it at an increased power value as compared with the input power, since the current induced by transformer action is superimposed upon the current generated in cutting the magnetic lines of force by motoring the secondary winding through the magnetic field. The direct application of AC power to the primary winding is contemplated, however the present and preferred embodiment employs commutation of DC power which is thereby inverted to AC power in the process of motoring the windings and the core in which they are carried together with the secondary winding. The net result is three fold, in that there is a motoring function, a transforming function, and a generating function, all of which are inherently synchronised to increase the output power with respect to the input power.

FIG.4.



From the foregoing it will be seen that this method, and the dynamo-electric converter termed a DEC, synchronously superimposes transformed electrical energy and mechanically generated electrical energy when inverting DC to AC as is shown by observing the oscilloscope diagram duplicated in **Fig.4** of the drawings. The DC motor section of the rotor-stator unit will operate at its designed speed well within a small tolerance, by applying known engineering principles, and consequently, the AC generator-alternator section will operate at a substantially uniform frequency of, for example, 60 cycles per second. Thus, the output voltage potential is kept to a maximum while current is drawn as required, within the design capacity of the unit.

Having described only a typical preferred form and application of my invention, I do not wish to be limited or restricted to the specific details herein set forth, but wish to reserve to myself any modifications or variations that may appear to those skilled in the art:

CLAIMS

1. A dynamo-electric converter for inverting direct current voltage to alternating current voltage and including; a magnetic field having poles of opposite polarity, an armature coaxial with the field and having a core with means to receive windings, coaxial bearing means between the field and the armature, a primary motor-transformer winding in said means of the armature core and a commutator connected therewith, direct current input brushes which can be engaged with the said commutator, a secondary transformer-generator winding in said means of the armature core and slip rings connected therewith, and alternating current output brushes which can be engaged with the said slip rings, whereby direct current input power is both transformed and regenerated as alternating output power.

2. The dynamo-electric converter as set forth in claim 1, wherein the magnetic field is a stator comprised of said poles of opposite polarity, and wherein the armature is a rotor supported upon said bearing means coaxially within said field.

3. The dynamo-electric converter as set forth in claim 1, wherein the means to receive windings is a pair of slots in the armature core, said primary and secondary windings being carried in the slots and subjected to the magnetic capabilities of the core.

4. The dynamo-electric converter as set forth in claim 1, wherein the means to receive windings is a multiplicity of slots disposed in a circumferential series about the armature core, said primary and secondary windings being circumferentially progressive windings respectively and carried in common slots respectively and subjected to the magnetic capabilities of the core.

5. The dynamo-electric converter as set forth in claim 1, wherein the magnetic field poles are permanent magnets.

6. The dynamo-electric converter as set forth in claim 1, wherein the magnetic field poles are electro magnets energised separately from the said primary motor winding.

7. The dynamo-electric converter as set forth in claim 1, wherein the field poles are electro magnets energised in parallel with the direct current input brushes which can be engaged with the commutator.

8. The dynamo-electric converter as set forth in claim 1, wherein the magnetic field is a stator comprised of said poles of opposite polarity, wherein the armature is a rotor supported on said bearing means coaxially within said field, and wherein the means to receive windings is a pair of slots in the armature core, said primary and secondary windings being carried in the slots and subjected to the magnetic capabilities of the core.

9. The dynamo-electric converter as set forth in claim 1, wherein the magnetic field is a stator comprised of permanent magnet poles of opposite polarity, wherein the armature is a rotor supported on said bearing means coaxially within said field, and wherein the means to receive windings is a pair of slots in the armature core, said primary and secondary windings being carried in the slots and subjected to the magnetic capabilities of the core.

10. The dynamo-electric converter as set forth in claim 1, wherein the magnetic field is a stator comprised of permanent magnet poles of opposite polarity, wherein the armature is a rotor supported on said bearing means coaxially within said field, and wherein the means to receive windings is a multiplicity of slots disposed in a circumferential series about the armature core, said primary and secondary windings being circumferentially progressive windings and carried in common slots respectively and subjected to the magnetic capabilities of the core.

11. The dynamo-electric converter is set forth in claim 1, wherein the magnetic field poles are electro magnets of opposite polarity energised in parallel with the direct current input brushes which can be engaged with the commutator, wherein the means to receive windings is a multiplicity of slots disposed in a circumferential series about the armature core, said primary and secondary windings being circumferentially progressive windings respectively and carried in common slots respectively and subjected to the magnetic capabilities of the core.

12. A method for increasing electrical power and comprised of; placing a primary winding within the flux of a magnetic field and applying alternating current therethrough while motoring the same to revolve, simultaneously revolving a secondary winding with the primary winding and through a flux of a magnetic field, and simultaneously transforming the first mentioned alternating current from the primary winding and into the secondary winding while synchronously generating alternating current in the secondary winding.

13. The method of increasing electrical power as set forth in claim 12 wherein the magnetic field is held stationary and the primary and secondary windings revolved together.

14. The method of increasing electrical power as set forth in claim 12 wherein the primary and secondary windings are related to a common armature synchronously inducing into and generating electrical power through the secondary winding.

15. The method of increasing electrical power as set forth in claim 12 wherein the first mentioned alternating current is commutated from direct current to alternating current by revolvement of said primary winding.

16. The method of increasing electrical power as set forth in claim 12 wherein the magnetic field is held stationary and the primary and secondary windings revolved together and related to a common armature synchronously inducing into and generating electrical power through the secondary winding.

17. The method of increasing electrical power as set forth in claim 12 wherein the first mentioned alternating current is commutated from direct current to alternating current by revolvement of said primary winding and the primary and secondary windings related to a common armature synchronously inducing into and generating electrical power through the secondary winding.

18. The method of increasing electrical power as set forth in claim 12 wherein the first mentioned alternating current is commutated from direct current to alternating current by revolvement of said primary winding and wherein the magnetic field is held stationary and the primary and secondary windings revolved together and related to a common armature synchronously inducing into and generating electrical power through the secondary winding.

19. A dynamo-electric machine including; a first means applying a first alternating current into a primary motor-transformer winding, and a second means inducing a second alternating current into a secondary transformer-generator winding, said secondary winding being carried by said second means to operate through a flux of a field and thereby generating a third alternating current, whereby said second and third alternating currents are synchronously superimposed one upon the other.

20. The dynamo-electric machine as set forth in claim 19 wherein the field is stationary and the primary and secondary windings are rotary.

21. The dynamo-electric machine as set forth in claim 19 wherein the field is stationary and the primary and secondary windings are rotary with commutator bars synchronously applying a direct current to motorise the armature and to apply said first alternating current thereto.

22. The dynamo-electric machine as set forth in claim 19 wherein the transformer means comprises magnetic core means common to the primary and secondary windings.

23. The dynamo-electric machine as set forth in claim 19, wherein the field is stationary and the primary and secondary windings are rotary with commutator bars synchronously applying a direct current to motorise the armature and to apply said first alternating current thereto, and wherein the transformer means comprises magnetic core means common to the primary and secondary windings.

24. A rotary dynamo-electric machine including: means applying alternating current through a primary motor-transformer winding carried by an armature core carrying a secondary transformer-generator winding, a field, and bearing means for rotation of the armature core relative to the field, whereby the alternating current applied to the primary winding motors the armature and is transformed and an alternating current generated and superimposed thereon through the secondary winding for increased output power.

25. The rotary dynamo-electric machine as set forth in claim 24 wherein the primary and secondary windings are each comprised of a number of turns of conductor to transform the first mentioned applied alternating current to the voltage of the alternating current generated through the secondary winding.

26. The rotary dynamo-electric motor as set forth in claim 24 wherein the first mentioned applied alternating current is of different voltage than the increased output power and wherein the primary and secondary windings are each comprised of a number of turns of conductor to transform the first mentioned applied alternating current to the voltage of the alternating current generated through the secondary winding.

27. The rotary dynamo-electric machine as set forth in claim 24 wherein the first mentioned applied alternating current is of lower voltage than the increased output power and wherein the primary and secondary windings are each comprised of a number of turns of conductor to transform the first mentioned applied alternating current to the voltage of the alternating current generated through the secondary winding.

SHIGEAKI HAYASAKA: INDUCTION GENERATOR

Patent US 5,892,311 6th April 1996 Inventor: Shigeaki Hayasaka

INDUCTION GENERATOR HAVING A PAIR OF MAGNETIC POLES OF THE SAME POLARITY OPPOSED TO EACH OTHER WITH RESPECT TO A ROTATION SHAFT

This patent covers a device which is claimed to have a greater output power than the input power required to run it.

ABSTRACT

An induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft is characterised by a high energy conversion efficiency. The induction generation has a rotation shaft driven by an external means; an even number of (more than three) stator cores provided to encircle the rotation shaft, predetermined gaps being provided between the adjacent stator cores; a first monopole rotor provided in the rotation shaft, surrounded by the even number of stator cores, and having first and second magnetic poles of the same polarity, the first and second magnetic poles being opposed to each other with respect to the rotation shaft in a cross section; a second monopole rotor provided in the rotation shaft so as to face the first monopole rotor at a predetermined distance along the rotation shaft, surrounded by the even number of stator cores, and having third and fourth magnetic poles of the same polarity opposite to the polarity of the first and second magnetic poles, the third and fourth magnetic poles being opposite to each other with respect to the rotation shaft; a plurality of windings provided in the even number of stator cores and connected according to a predetermined configuration.

DESCRIPTION

TECHNICAL FIELD

The present invention relates to an induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft.

Induction generators have been known as one type of electrical appliance from relatively old days and embodied in various forms adapted for individual applications. In addition to applications in power plants, ships and aircraft, induction generators convenient for household or leisure purposes have also been developed and used extensively.

An induction generator converts kinetic energy into electric energy. Due to a necessity for improving efficiency of energy utilisation, there is a demand for a highly efficient energy conversion.

BACKGROUND ART

As is well known, an induction generator is operated on the principle that an electromotive force is induced in a coil, in proportion to the rate at which magnetic flux crosses that coil (Faraday's law of electromagnetic induction). According to Lenz's law, an induced electromotive force is generated in a direction in which a current that acts against a change in the magnetic flux is generated.

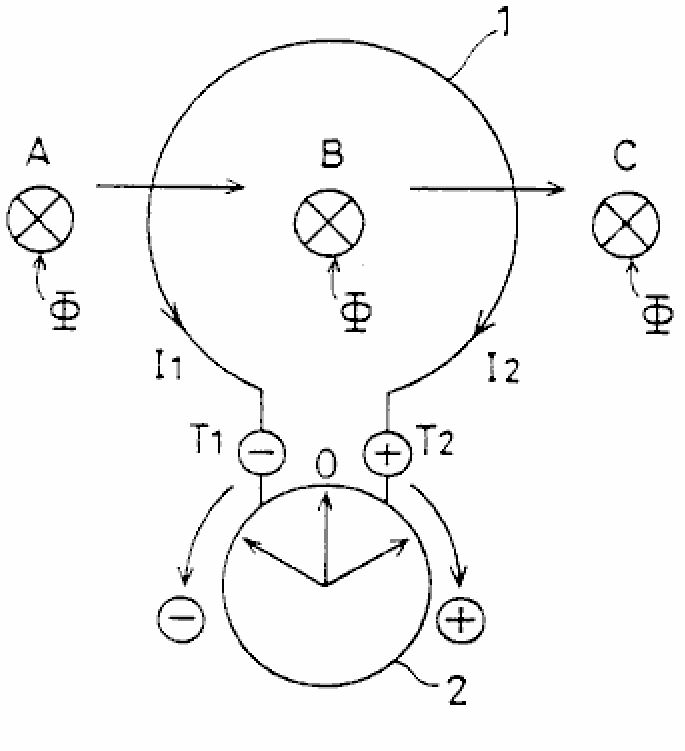

FIG. 1A

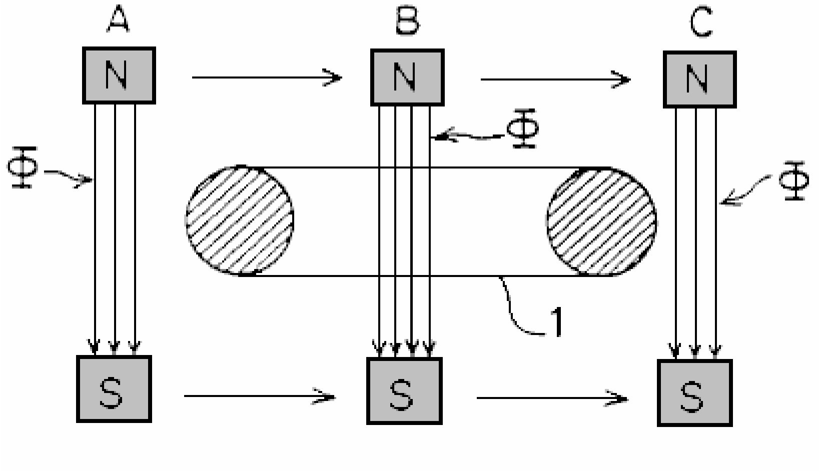

FIG. 1B

For example, as shown in **Fig.1A** and **Fig.1B**, assuming that the magnetic flux **phi** crossing a circular coil **1** at a perpendicular direction moves in the **A to B** direction as indicated by the arrow, a current $\mathbf{I_1}$ flows in accordance with Faraday's law of electromagnetic induction so that the pointer of a galvanometer **2** swings clockwise (+ direction) and then returns to the zero position. When the magnetic flux **phi** moves in the direction **B to C**, a current $\mathbf{I_2}$ flows so that the indicator of the galvanometer **2** swings counterclockwise (- direction) and then returns to the zero position.

Generally, an induction generator is constructed in such a way that an electromotive force is induced according to Flemming's right-hand rule by a conductor cutting magnetic flux lines (**Fig.1A**) or by the magnetic flux lines crossing the conductor (**Fig.1B**).

A rotor in an induction generator is usually constructed as a one-piece body having alternately disposed North poles and South poles. When there are two magnetic poles, the N-pole and the S-pole are opposite to each other. When there are more than two magnetic poles (for example, four magnetic poles or six magnetic poles etc.), the N-pole and the S-pole alternate, resulting in a N-S-N-S- . . . succession.

In this background, a unipolar induction generator is a special case wherein an electromotive force is generated by a conductor cutting the magnetic flux while moving or rotating, and a direct current is supplied through a slip ring. In other words, a unipolar induction motor is unique in its construction characterised by a non-alternating magnetic field travelling in the same direction.

In the conventional induction generator such as the one described above, improvement in energy conversion efficiency is attained such that the rotor is constructed of a ferrite, or rare-earth, magnet characterised by a high energy product and a small reversing permeability (recoil permeability). Alternatively, the extent of demagnetisation due to generation of a counter magnetic field in an induction coil is reduced allowing the single polarity of the rotor to interact with the stator in forming a magnetic circuit. However, despite these measures, reduction in energy conversion efficiency due to a counter magnetic field of the rotor core, more specifically, due to demagnetisation resulting from the counter magnetic field caused by armature reaction presents a serious problem.

The present invention has been developed in view of the above points, and its object is to provide an induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft, wherein a high energy conversion efficiency is attained.

DISCLOSURE OF THE INVENTION

The present invention provides an induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft, characterised by comprising:

A rotation shaft driven by external means;

An even number of (more than three) stator cores provided to encircle the rotation shaft, predetermined gaps being provided between the adjacent stator cores;

A first single-opposed polarity rotor provided in the rotation shaft, surrounded by the even number of stator cores, and having first and second magnets magnetised such that the even number of stator cores remain facing a first polarity, the first and second magnets being opposed to each other with respect to the rotation shaft in a cross section;

A second single-opposed-polarity rotor provided in the rotation shaft so as to face the first single-opposed-polarity rotor at a predetermined distance along the rotation shaft, surrounded by the even number of stator cores, and having third and fourth magnets magnetised such that the even number of stator cores remain facing a second polarity which is opposite to the polarity of the first polarity, the third and fourth magnets being disposed opposite to each other with respect to the rotation shaft;

A plurality of windings provided in the even number of stator cores and connected according to a predetermined configuration, characterised in that:

A rotating magnetic field which causes electromagnetic induction in the even number of stator cores successively is created by the first, second, third and fourth magnets when the first and second single-opposed-polarity rotors are rotated; and

Periodic increase and decrease in the number of magnetic flux lines crossing a given winding and associated periodic decrease and increase crossing an adjacent winding causes a periodic electromotive force having a rectangular waveform to be output.

In one aspect of the present invention, the plurality of windings connected according to the predetermined configuration form first and second serial circuits:

The first serial circuit outputs a periodic first electromotive force having a rectangular waveform when a rotating magnetic field which causes electromagnetic induction in the even number of stator cores successively is created by the first, second, third and fourth magnets when the first and second single-opposed-polarity rotors are rotated; and

The second serial circuit outputs a periodic second electromotive force of a rectangular waveform 180^0. out of phase with the first electromotive force and having the same period as the first electromotive force, when a rotating magnetic field which causes electromagnetic induction in the even number of stator cores successively is created by the first and second single-opposed-polarity rotors are rotated.

The induction generator of the present invention may also comprise:

Rotation position detecting means for detecting a position of the first and second single-opposed-polarity rotors during their rotation; and

Switching means which alternately causes positive components of the first electromotive force having a rectangular waveform and provided by the first serial circuit, or positive components of the second electromotive force having a rectangular waveform and provided by the second serial circuit to be output at intervals of an electrical angle of 180^0.

In another aspect of the present invention, the plurality of windings comprise a first winding provided in a first stator core of the even number of stator cores, a second winding provided in a second stator core adjacent to the first stator core so as to wind in a direction opposite to a direction in which the first winding is provided, a third winding provided in a third stator core adjacent to the second stator core so as to wind in the same direction as the first winding, a fourth winding provided in a fourth stator core adjacent to the third stator core so as to wind in a direction opposite to a direction in which the third winding is provided, the first through fourth windings being connected with each other according to a predetermined configuration.

In still another aspect of the present invention, the first serial circuit comprises a first winding provided to wind in a first direction in a first stator core of the even number of stator cores, a second winding serially connected to the first winding and provided in a second stator core adjacent to the first stator core so as to wind in a second direction opposite to the first direction, a third winding serially connected with the second winding and provided in a third stator core adjacent to the second stator core so as to wind in the first direction, a fourth winding serially connected to the third winding and provided in a fourth stator core adjacent to the third stator core so as to wind in the second direction; and

The second serial circuit comprises a fifth winding provided to wind in the second direction in the first stator core, a sixth winding serially connected to the fifth winding and provided in the second stator core so as to wind in the first direction, a seventh winding serially connected with the sixth winding and provided in the third stator core so as to wind in the second direction, an eighth winding serially connected to the seventh winding and provided in the fourth stator core so as to wind in the first direction.

In yet another aspect of the present invention, the first through fourth magnets are arc-shaped; and

the even number of stator cores have arc-shaped cross sections.

In still another aspect of the present invention, the arc-shaped first through fourth magnets and the stator cores which have arc-like cross sections have an almost identical circumferential length.

BRIEF DESCRIPTION OF THE DRAWINGS

BEST MODE FOR CARRYING OUT THE INVENTION

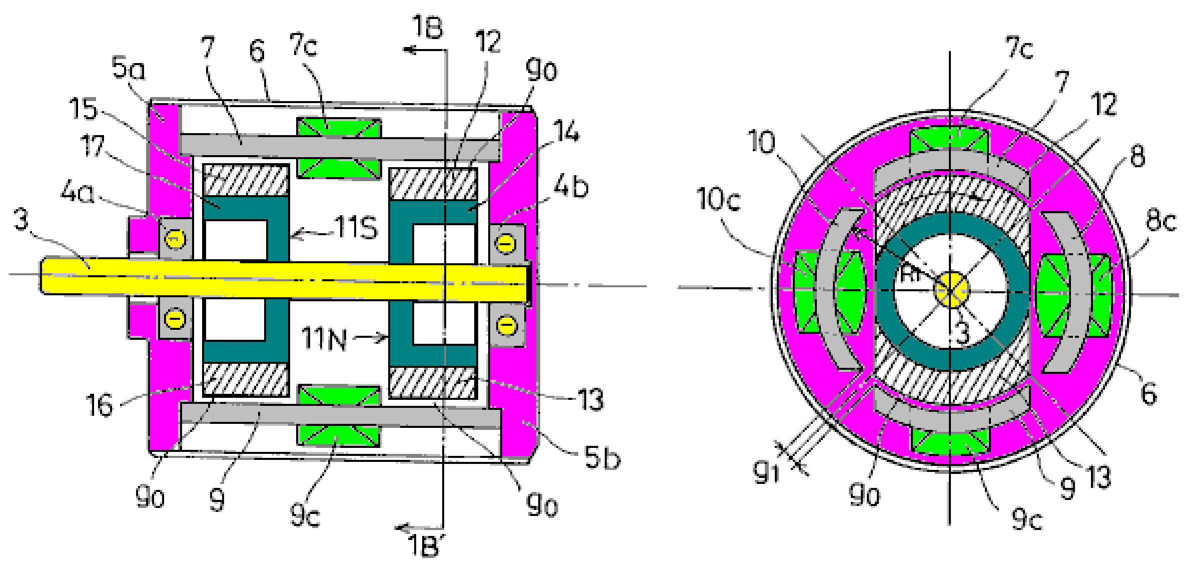

FIG. 2A FIG. 2B

Fig.2A and **Fig.2B** show a first embodiment of the present invention. Specifically, **Fig.2A** is a longitudinal sectional view and **Fig.2B** is a cross-sectional view taken in the line **1B-1B'** of **Fig.2A**.

Referring to **Fig.2A** and **Fig.2B**, **3** indicates a rotation shaft formed of a non-magnetic material and driven by an external means; **4a** and **4b** bearings for supporting the rotation shaft **3**; **5a** and **5b** are flanges provided with the bearings **4a** and **4b**, respectively; and **6** is a cylindrical case cover for accommodating the flanges **5a** and **5b**.

Stator cores **7**, **8**, **9** and **10** are arranged so as to encircle the rotation shaft **3**, equidistant gaps $\mathbf{g_1}$ being provided between the adjacent stator cores. Each of the stator cores **7**, **8**, **9** and **10** has the same arc-like cross section.

A single-opposed-polarity N-pole rotor **11N** and a single-opposed-polarity S-pole rotor **11S** are provided on the rotation shaft **3** so as to be opposite to each other. The single-opposed-polarity rotors **11N** and **11S** are surrounded by the stator cores **7**, **8**, **9** and **10**, a small rotation gap $\mathbf{g_0}$ being provided between the single-opposed-polarity rotor and the stator core.

Referring to **Fig.2B**, windings **7c** and **9c** are provided clockwise around the stator cores **7** and **9**, respectively. Windings **8c** and **10c** are wound counterclockwise around the stator cores **8** and **10**, respectively. The windings **7c**, **8c**, **9c** and **10c** are connected with each other in a configuration described later.

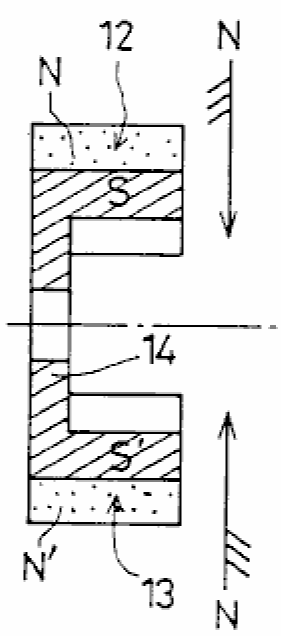

FIG. 3A

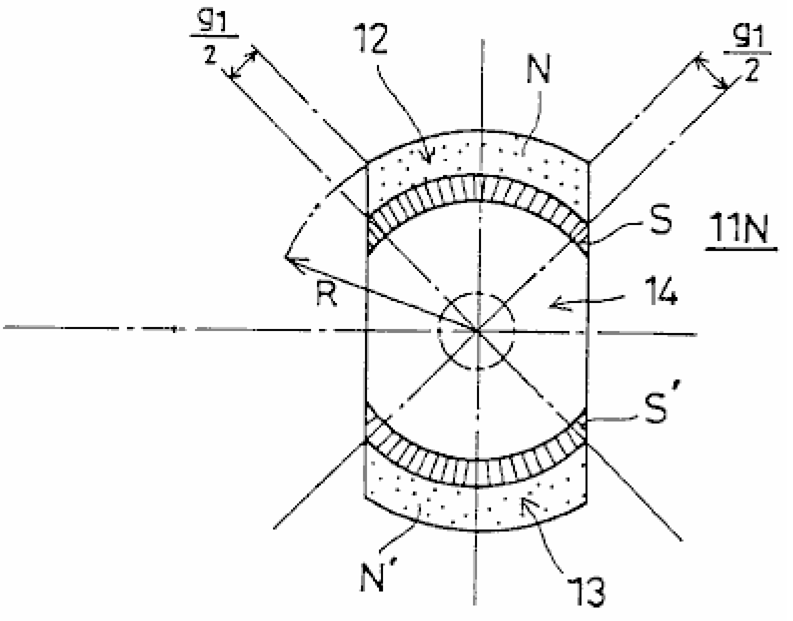

FIG. 3B

Fig.3A and **Fig.3B** show the single-opposed-polarity rotor **11N**. Specifically, **Fig.3A** is a longitudinal sectional view, and **Fig.3B** is a cross-sectional view. The single-opposed-polarity rotor **11N** has arc-shaped magnets **12** and **13** which are 180^0 displaced from each other and are magnetised such that their surfaces which face the stator cores **7-10** are N-poles while their inner surfaces are S-poles. The arc-shaped magnets **12** and **13** are configured to match the outline of the stator cores **7**, **8**, **9** and **10**. Referring to **Fig.3B**, the symbols **N** and **N'** are used so as to differentiate between the magnets **12** and **13**.

A rotor piece **14** is positioned so as to connect the arc-shaped magnets **12** and **13**. The rotor piece **14** is magnetised by the arc-shaped magnets **12** and **13** so that it's surfaces which face the arc-shaped magnets **12** and **13** are S-poles and is formed of a substance (for example, a silicon steel) constructed of a low carbon steel having mixed therein several percent of non-ferrous metal subjected to a forging-cast process. The iron core embodied by the rotor piece **14** thus constructed is characterised by a well-balanced magnetic field where the permeability approximates a peak value in a unipolar magnetic field that the iron core presents to its surroundings.

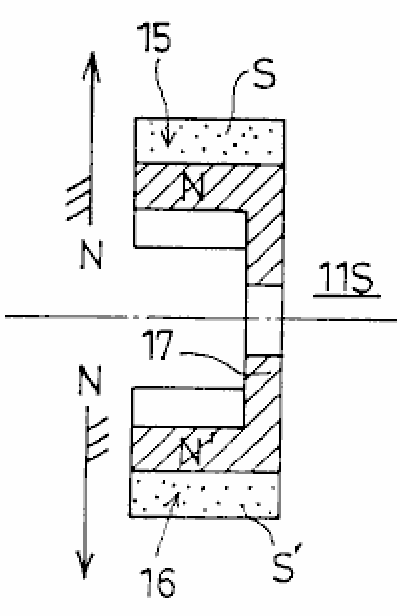

FIG. 4A

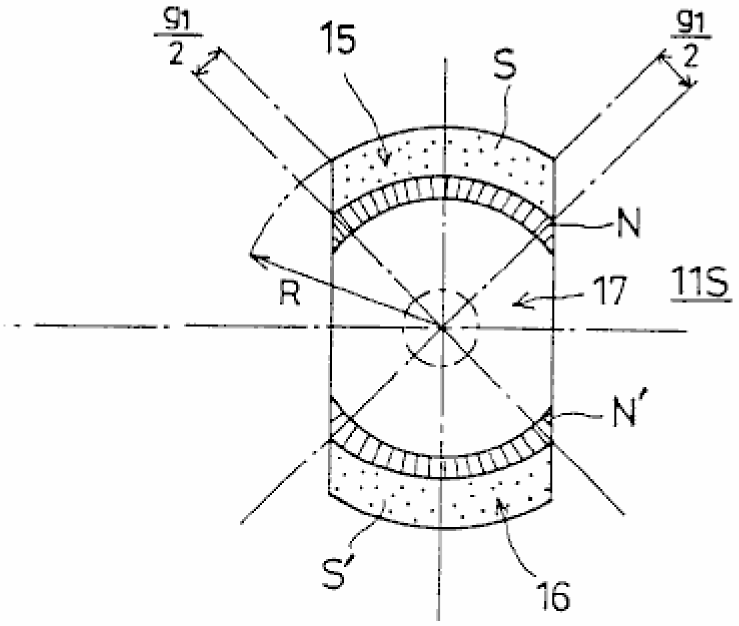

FIG. 4B

Fig.4A and **Fig.4B** show the single-opposed-polarity rotor **11S**. Specifically, **Fig.4A** is a longitudinal sectional view, and **Fig.4B** is a cross-sectional view.

The single-opposed-polarity rotor **11S** has arc-shaped magnets **15** and **16** which are 180^0 displaced from each other and are magnetised such that the surfaces thereof facing the stator cores **7-10** are S-poles while their inner surfaces are N-poles. The arc-shaped magnets **15** and **16** are configured to match the outline of the stator cores **7**, **8**, **9** and **10**.

A rotor piece 17 is positioned so as to connect the arc-shaped magnets **15** and **16**. The rotor piece **17** is magnetised by the arc-shaped magnets **15** and **16** so that it's surfaces which face the arc-shaped magnets **15** and **16** are N-poles. The rotor piece is made from a substance constructed from a low carbon steel having mixed in it, several percent of non-ferrous metal subjected to a forging-cast process. The iron core embodied by the rotor piece **17** thus constructed is characterised by a well-balanced magnetic field where the permeability approximates a peak value in a unipolar magnetic field that the iron core presents to its surroundings.

The arc-shaped magnets **12**, **13**, **15** and **16** have the same circumferential length, which is also equal to the length of the arc formed by the circumference of the stator cores **7**, **8**, **9** and **10**. More specifically, this length is obtained by dividing the entire hypothetical circumference minus the four g_1 gaps by four. Referring to **Fig.2A** and **Fig.2B**, the rotation gap g_0 is equal to $R_1 - R$, where R_1 is a distance between the centre of the rotation shaft **3** and the inner surface of the stator cores **7-10**, and **R** is a distance between the centre of the rotation shaft **3** and the outer surface of the single-opposed-polarity rotors **11N** and **11S**, as indicated in **Fig.3B** and **Fig.4B**.

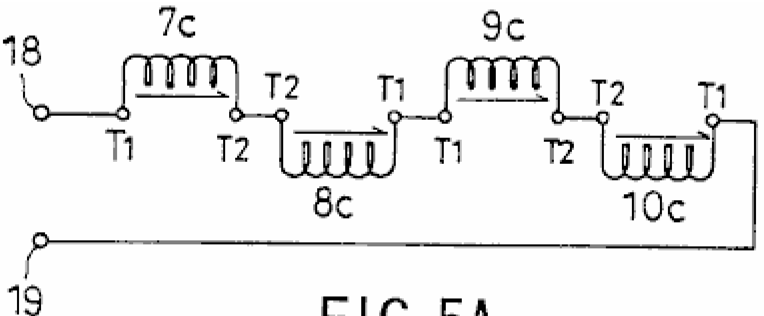

FIG. 5A

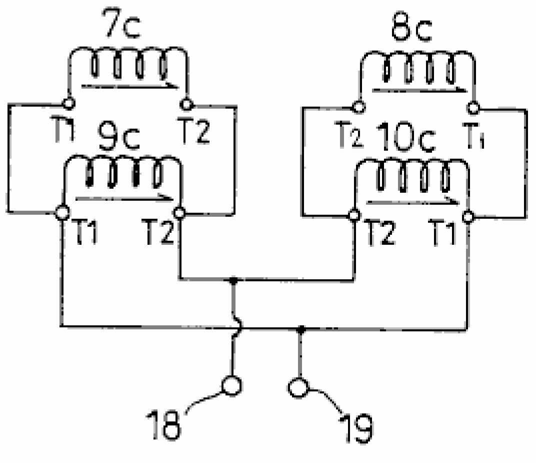

FIG. 5B

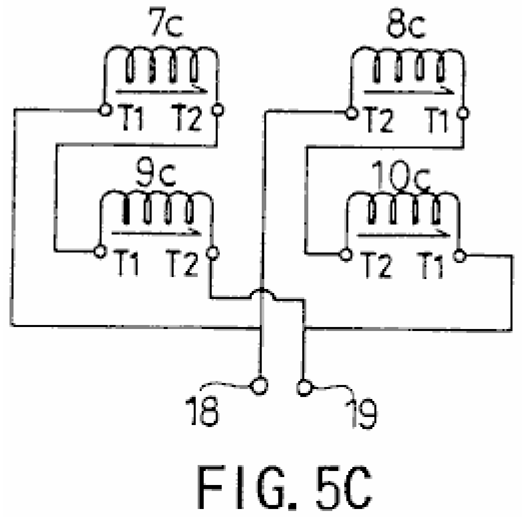

FIG. 5C

Fig.5A, **Fig.5B** and **Fig.5C**, show how the wirings are connected with each other. $\mathbf{T_1}$ indicates the beginning of a winding, $\mathbf{T_2}$ the end of a winding, and **18** and **19** output terminals. More specifically, **Fig.5A** shows a serial connection configuration, **Fig.5B** a serial-parallel connection configuration, and **Fig.5C** a parallel connection configuration. The serial connection configuration allows the electromotive force induced in the windings to be added together and provides a high-voltage output. The parallel connection configuration allows currents resulting from the electromotive force induced in the windings to be added together and provides a large-current output.

A description will now be given, with reference to **Fig.6A**, **Fig.6B** and **Fig.7**, of power generation operation of the serial connection configuration.

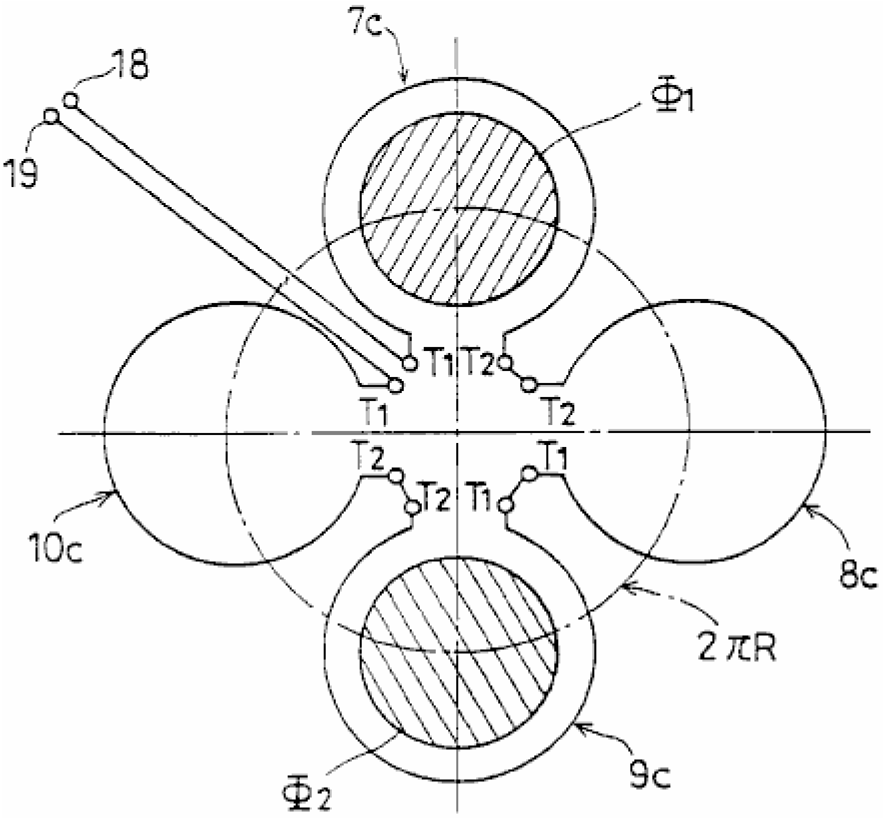

FIG. 6A

Fig.6A is a diagram showing schematically how the rotating magnetic field provided by the single-opposed-polarity rotors **11S** and **11N** crosses windings **7c-10c**. **Fig.6B** shows a magnetic path.

Referring to **Fig.6A**, $\mathbf{Phi_1}$ and $\mathbf{Phi_2}$ indicate rotating magnetic flux rotating along the circumference 2Pi x R. **Fig.6B** shows the arc-shaped magnets **12** and **15** directly opposite the stator core **7** over their entire length, and the arc-shaped magnets **13** and **16** directly opposite the stator core **9** over their entire length.

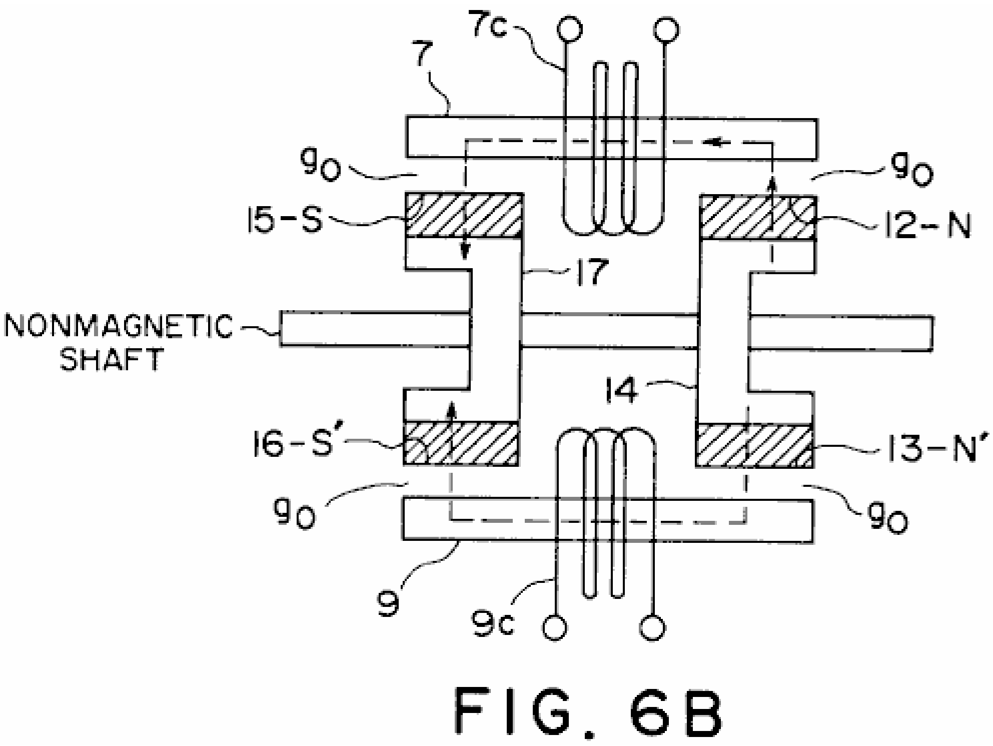

FIG. 6B

As shown in **Fig.6B**, the magnetic flux **Phi$_1$** forms a magnetic path as follows:

The rotor piece **14** (S) - the arc-shaped magnet pole **12** (N) - stator core **7** - the rotation gap **g$_0$** - the arc-shaped magnet **15** (S) - the rotor piece **17** (N).

The magnetic flux **Phi$_2$** forms a magnetic path as follows:

The rotor piece **14** (S) - the arc-shaped magnet **13** (N) - the rotation gap **g$_0$** - the stator core **9** - the rotation gap **g$_0$** - the arc-shaped magnet **16** (S) - the rotor piece **17** (N).

Thus, a parallel magnetic path is formed. In this state, the magnetic flux **Phi$_1$** crosses the winding **7c**, and the magnetic flux **Phi$_2$** crosses the winding **9c**.

A description focused on the rotation of the magnetic flux **Phi$_1$** is given. Specifically, a description will be given of a change in the way the magnetic flux **Phi$_1$** crosses the windings.

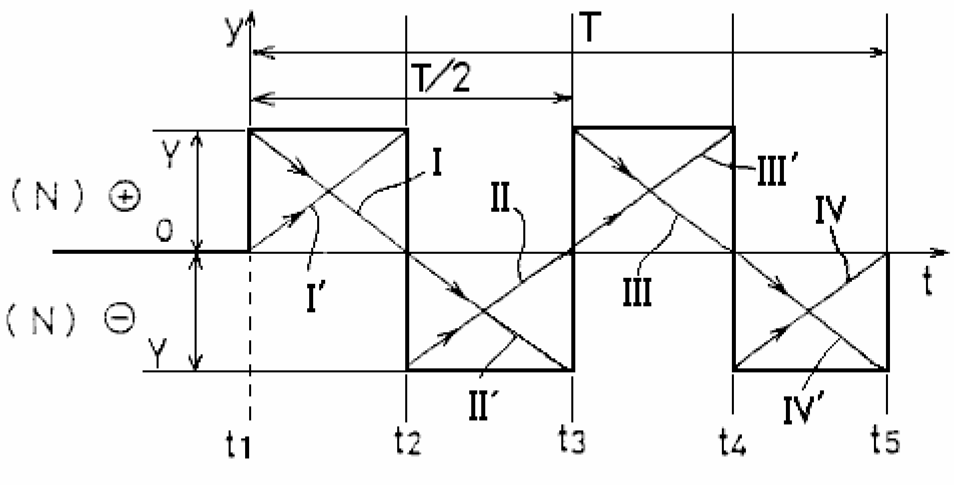

FIG. 7

Referring to a waveform of an output voltage shown in **Fig.7**, the entirety of the magnetic flux **Phi$_1$** crosses the winding **10c** at a time **t$_1$**. At a time **t$_2$**, the entirety of the magnetic flux **Phi$_1$** crosses the winding **7c**. At a time **t$_3$**, the entirety of the magnetic flux **Phi$_1$** crosses the winding **8c**. At a time **t$_4$**, the entirety of the magnetic flux **Phi$_1$** crosses the winding **9c**. At a time **t$_5$**, the entirety of the magnetic flux **Phi$_1$** crosses the winding **10c**. In this way, the magnetic flux **Phi$_1$** rotates at a constant speed during a time **T**, in a clockwise direction in **Fig.6A**.

Between the time **t$_1$** and the time **t$_2$**, an electromotive force having a descending triangular waveform, indicated by **I** in **Fig.7**, is generated in the winding **10c** due to a decrease in the number of magnetic flux lines of the magnetic flux **Phi** crossing the winding **10c**. An electromotive force having an ascending triangular waveform, indicated by **I'** in **Fig.6**, is generated in the winding **7c** due to an increase in the number of magnetic flux lines of the magnetic flux **Phi** crossing the winding **7c**. Accordingly, a positive rectangular waveform obtained by the sum of these triangular waveforms is output to the output terminals **18** and **19**.

Between the time **t$_2$** and the time **t$_3$**, an electromotive force having an ascending triangular waveform, indicated by **II** in **Fig.7**, is generated in the winding **7c** due to a decrease in the number of magnetic flux lines of the magnetic flux **Phi** crossing the winding **7c**. An electromotive force having a descending triangular waveform, indicated by **II'** in **Fig.7**, is generated in the winding **8c** due to an increase in the number of magnetic flux lines of the magnetic flux **Phi** crossing the winding **8c**. Accordingly, a negative rectangular waveform obtained by the sum of these triangular waveforms is output to the output terminals **18** and **19**.

Between the time **t$_3$** and the time **t$_4$**, an electromotive force having a descending triangular waveform, indicated by **III** in **Fig.7**, is generated in the winding **8c** due to a decrease in the number of magnetic flux lines of the magnetic flux **Phi** of the magnetic flux **Phi** crossing the winding **8c**. An electromotive force having an ascending triangular waveform, indicated by **III'** in **Fig.7**, is generated in the winding **9c** due to an increase in the number of magnetic flux lines of the magnetic flux **Phi** crossing the winding **9c**. Accordingly, a positive rectangular waveform obtained by the sum of these triangular waveforms is output to the output terminals **18** and **19**.

Between the time **t$_4$** and the time **t$_5$**, an electromotive force having an ascending triangular waveform, indicated by **IV** in **Fig.7**, is generated in the winding **9c** due to a decrease in the number of magnetic flux lines of the magnetic flux **Phi** crossing the winding **9c**. An electromotive force having a descending triangular waveform, indicated by **IV'** in **Fig.7**, is generated in the winding **10c** due to an increase in the number of magnetic flux lines of the magnetic flux **Phi** crossing the winding **10c**. Accordingly, a negative rectangular waveform obtained by the sum of these triangular waveforms is output to the output terminals **18** and **19**.

While the magnetic flux **Phi$_1$** makes one rotation, an electromotive force having a synthesised rectangular waveform and a period of **T/2** is output, as shown in **Fig.7**. Since the magnetic flux **Phi$_2$** also makes one rotation while the magnetic flux **Phi$_1$** makes one rotation and produces an output of an electromotive force having a similar rectangular waveform, the magnitude of the electromotive force obtained between the terminals **18** and **19** is actually double that indicated in **Fig.7**.

In this way, this embodiment makes it possible to cancel a counter magnetic field and provide an induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft and characterised by a high energy conversion efficiency. Our operating practice has confirmed that the generator having the construction of this embodiment provides an energy conversion efficiency which is high enough to require only 1/5.2 of the driving torque for the conventional generator.

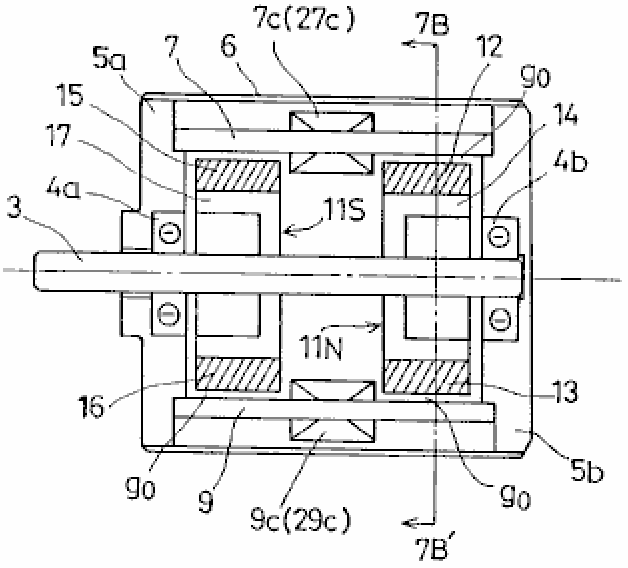

FIG. 8A

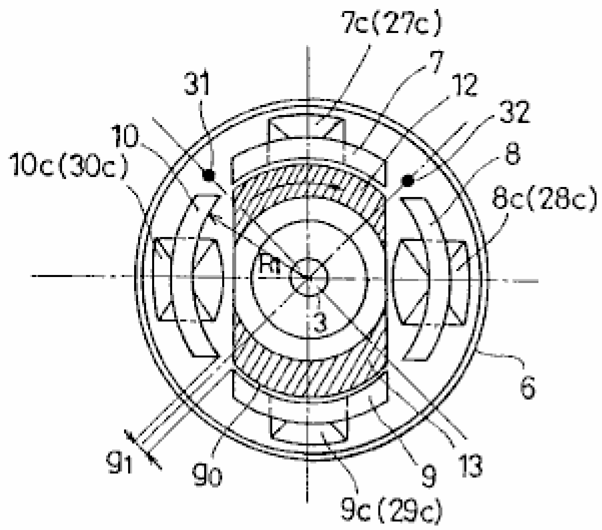

FIG. 8B

Fig.8A and **Fig.8B** show a second embodiment of the present invention. Specifically, **Fig.8A** is a longitudinal sectional view, and **Fig.8B** is a cross-sectional view taken in the line **7B-7B'** of **Fig.8A**.

Referring to **Fig.8A** and **Fig.8B**, **3** indicates a rotation shaft formed of a non-magnetic material and driven by an external source; **4a** and **4b** are bearings which support the rotation shaft **3**, **5a** and **5b** are flanges housing the bearings **4a** and **4b**, and **6** is a cylindrical case cover for accommodating the flanges **5a** and **5b**.

Stator cores **7**, **8**, **9** and **10** are arranged so as to encircle the rotation shaft **3**, equidistant gaps $\mathbf{g_1}$ being provided between the adjacent stator cores. Each of the stator cores **7**, **8**, **9** and **10** has a same arc-like cross section.

A single-opposed-polarity N-pole rotor **11N** and a single-opposed-polarity S-pole rotor **11S** are provided on the rotation shaft **3** so as to be opposite to each other. The single-opposed-polarity rotors **11N** and **11S** are surrounded by the stator cores **7**, **8**, **9** and **10** a small rotation gap $\mathbf{g_0}$ being provided between the single-opposed-polarity rotor and the stator core.

Referring to **Fig.8B**, windings **7c** and **9c** are provided clockwise around the stator cores **7** and **9**, respectively. Windings **27c** and **29c** are provided counterclockwise around the stator cores **7** and **9**, respectively. Windings **8c** and **10c** are provided counterclockwise in the stator cores **8** and **10**, respectively. Windings **28c** and 30c are wound clockwise around the stator cores 8 and 10, respectively. The windings 7c, 8c, 9c, 10c, **27c**, **28c**, **29c** and **30c** are connected with each other according to a configuration described later.

A magnetic sensor (for rotation position detection) **31** is provided between the stator cores **7** and **10**, and a magnetic sensor (for rotation position detection) **32** is provided between the stator cores **7** and **8**. The magnetic sensors **31** and **32** detect the magnetic field so as to determine the position of the single-opposed-polarity rotors **11N** and **11S** during their rotation.

The single-opposed-polarity rotors **11N** has a configuration as shown in **Fig.3A** and **Fig.3B**, and the monopole rotor **11S** has a configuration as shown in **Fig.4A** and **Fig.4B**.

The single-opposed-polarity rotor **11N** has arc-shaped magnets **12** and **13** which are 180^0 displaced from each other and are magnetised such that their surfaces facing the stator cores are N-poles while their respective inner surfaces are S-poles. The arc-shaped magnets **12** and **13** are configured to match the outline of the stator cores **7**, **8**, **9** and **10**.

A rotor piece **14** is positioned so as to connect the arc-shaped magnets **12** and **13**. The rotor piece **14** is constructed from a low-carbon steel having several percent of non-ferrous metal, using a forging-cast process. The iron core rotor piece **14** constructed by this means, has a well-balanced magnetic field where the permeability approximates a peak value in a unipolar magnetic field that the iron core presents to its surroundings.

The single-opposed-polarity rotor **11S** has arc-shaped magnets **15** and **16** which are positioned 180^0 apart from each other and are magnetised so that their surfaces which face the stator cores are S-poles while their inner surfaces are N-poles. The arc-shaped magnets **15** and **16** are shaped and positioned so as to match the outline of the stator cores **7**, **8**, **9** and **10**.

A rotor piece **17** is positioned so as to connect the arc-shaped magnets **15** and **16**. The rotor piece **17** is constructed from a low-carbon steel having several percent of non-ferrous metal, using a forging-cast process. The iron core rotor piece **17** constructed by this means, has a well-balanced magnetic field where the permeability approximates a peak value in a unipolar magnetic field which the iron core presents to its surroundings.

The arc-shaped magnets **12**, **13**, **15** and **16** have the same circumferential lengths, which is equal to the length of the arc formed by the circumference of the stator cores **7**, **8**, **9** and **10**. More specifically, this length is obtained by dividing by four, the entire hypothetical circumference minus the four gaps $\mathbf{g_1}$. Referring to **Figs. 3A, 3B, 4A, 4B** and **8**, the rotation gap $\mathbf{g_0}$ is equal to $\mathbf{R_1}$ **-R**.

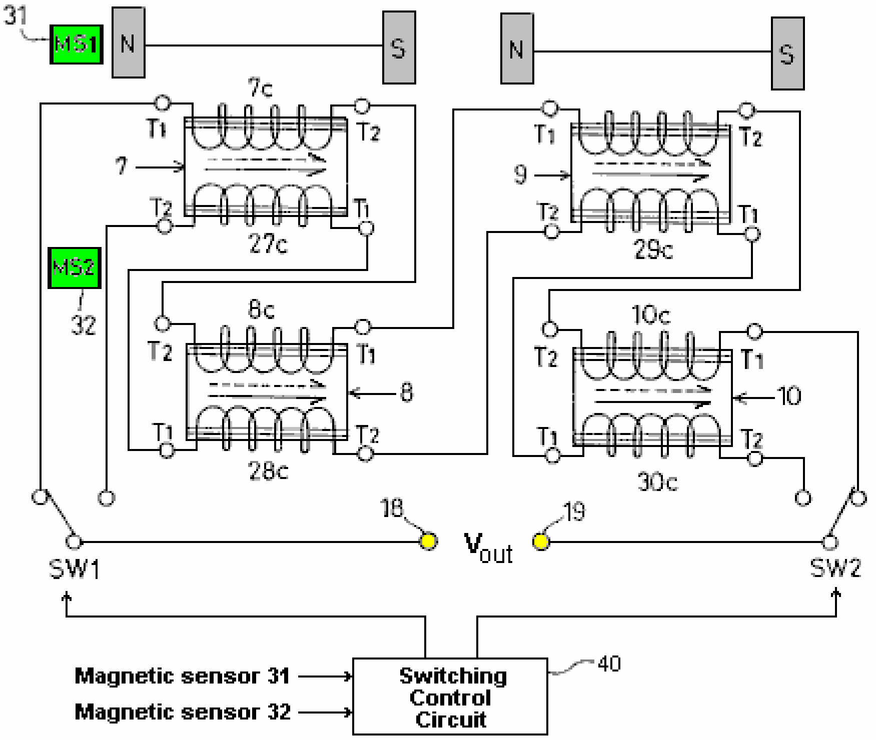

FIG. 9

Fig.9 shows how the wirings are connected with each other. $\mathbf{T_1}$ indicates the beginning of a winding, $\mathbf{T_2}$ the end of a winding, and **18** and **19** are the output terminals.

Two serial circuits are formed out of the windings. Switches **SW1** and **SW2** are used for selection of the respective serial circuits. A switching control circuit **40**, which processes a detection signal from the magnetic sensors **31** and **32**, drives the switches SW1 and SW2 selectively in accordance with the detection signal.

As shown in **Fig.9**, the first serial circuit comprises the winding **7c** provided clockwise in the stator core **7**, the winding **8c** serially connected with the winding **7c** and provided counterclockwise in the stator core **8** adjacent to the stator core **7**; the winding **9c** serially connected with the winding **8c** and provided clockwise in the stator core **9**; and the winding **10c** serially connected with the winding **9c** and provided counterclockwise in the stator core **10** adjacent to the stator core **9**.

As shown in **Fig.9**, the second serial circuit comprises the winding **27c** provided counterclockwise in the stator core **7**; the winding **28c** serially connected with the winding **27c** and provided clockwise in the stator core **8**; the winding **29c** serially connected with the winding **28c** and provided counterclockwise in the stator core **9**; and the winding **30c** serially connected with the winding **29c** and provided clockwise in the stator core **10**.

According to the construction described above, a rotating magnetic field which causes electromagnetic induction in the stator cores **7-10** successively is created by the arc-shaped magnets **12**, **13**, **15** and **16** when the single-opposed-polarity rotors **11N** and **11S** are rotated. As has been already explained with reference to **Fig.6A**, **Fig.6B** and **Fig.7**, as the magnetic flux lines crossing one of the windings **7c-10c** increase in number, the magnetic flux lines crossing the adjacent one of the windings **7c-10c** decrease in number. That is, the magnetic flux lines periodically increase and decrease with respect to a given winding so that a first electromotive force, having a rectangular waveform similar to the one shown in **Fig.7** and a period that is 1/2 the period of the rotation, is output from the first serial circuit (**7c-10c**).

As the magnetic flux lines crossing one of the windings **27c-30c** increase in number, the magnetic flux lines crossing the adjacent one of the windings **27c-30c** decrease in number. That is, the magnetic flux lines periodically increase and decrease with respect to a given winding so that a second electromotive force of a rectangular waveform 180^0 out of phase with the first electromotive force and having the same period as the first electromotive force is output from the second serial circuit (**27c-30c**). That is, the second electromotive force is 180^0 out of phase with the electromotive force shown in **Fig.7**.

Referring to **Fig.10**, in accordance with the detection signal from the magnetic sensors **31** and **32**, the switches **SW1** and **SW2** effect switching at 90^0 intervals. By that means, the positive components **I** and **III** of the first electromotive force having a rectangular waveform and provided from the first serial circuit, and the positive components **II** and **IV** of the second electromotive force having a rectangular waveform and provided from the second serial circuit are alternately selected at 180^0 intervals and output to the output terminals **18** and **19**.

This means that, this embodiment ensures a high-efficiency energy conversion wherein a counter magnetic field is cancelled, and a DC electromotive force having a positive level is properly synthesised and output. It is of course possible to synthesise and output a negative DC electromotive force by shifting the switching timing by 180^0.

INDUSTRIAL APPLICABILITY

As has been described, according to the present invention, the rotation of the first and second single-opposed-polarity rotors generates a rotating magnetic field which causes an induction in an even number of stator cores successively. As the magnetic flux lines crossing one of the first-through-fourth windings increase in number, the magnetic flux lines crossing the adjacent one of the first-through-fourth windings decrease in number. That is, the magnetic flux lines periodically increase and decrease with respect to a given winding. The electromotive force generated as the magnetic flux lines crossing a winding increase in number and the electromotive force generated as the magnetic flux lines crossing an adjacent winding decrease in number are synthesised so that a periodic AC electromotive force having a rectangular waveform is generated out of the synthesis and output. In this way, a high-efficiency energy conversion wherein a counter magnetic field is cancelled is provided.

According to the first serial circuit of the present invention, the rotation of the first and second single-opposed-polarity rotors generates a rotating magnetic field which causes an induction in an even number of stator cores successively. As the magnetic flux lines crossing one of the first through fourth windings increase in number, the magnetic flux lines crossing the adjacent one of the first through fourth windings decrease in number. That is, the magnetic flux lines periodically increase and decrease in a given winding. Accordingly, the first electromotive force having a rectangular waveform is output. According to the second serial circuit, as the magnetic flux lines crossing one of the fifth-through-eighth windings increase in number, the magnetic flux lines crossing the adjacent one of the fifth-through-eighth windings decrease in number. That is, the magnetic flux lines periodically increase and decrease in a given winding. Accordingly, the second electromotive force 180^0 out of phase with the first electromotive force and having the same period as the first electromotive force is output. In accordance with the detection signal from the rotation position detecting means, the switching means selectively causes the positive components of the first electromotive force provided by the first serial circuit, or the positive components of the second electromotive force provided by the second serial circuit to be output at 180^0 intervals. In this way the DC electromotive force is synthesised and output. This results in a high-efficiency energy conversion where a counter magnetic field is cancelled.

In addition to extensive applications in power plants, ships, aircraft etc., the present invention may find household applications or may be conveniently adapted for leisure uses.

CLAIMS

1. An induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft, characterised by comprising:

a rotation shaft driven by external means;

an even number of (more than three) stator cores provided to encircle said rotation shaft, predetermined gaps being provided between the adjacent stator cores;

a first single-opposed-polarity rotor provided on said rotation shaft, surrounded by said even number of stator cores, and having first and second magnets magnetised such that said even number of stator cores remain facing a first polarity, said first and second magnets sandwiching a magnetic body between them and being opposed to each other with respect to said rotation shaft in a cross section;

a second single-opposed-polarity rotor provided on said rotation shaft so as to face said first single-opposed-polarity rotor at a predetermined distance along the rotation shaft, surrounded by said even number of stator cores, and having third and fourth magnets magnetised such that said even number of stator cores remain facing a second polarity which is opposite to the polarity of said first polarity, said third and fourth magnets sandwiching a magnetic body between them and being disposed opposite to each other with respect to said rotation shaft;

a plurality of windings provided in said even number of stator cores and connected according to a predetermined configuration, characterised in that: a rotating magnetic field which causes electromagnetic induction in said even number of stator cores successively is created by the first, second, third and fourth magnets when said first and second single-opposed-polarity rotors are rotated; and

two windings adjacent to each other are wound in opposite directions and connected in series so that a rectangular waveform is formed by synthesising the electromotive forces generated by the two windings, so that an electromotive force having a triangular waveform caused by periodic increase and decrease in the number of magnetic flux lines crossing one of the two windings and another electromotive force having a triangular waveform caused by associated periodic decrease and increase in the number of magnetic flux lines crossing the other one of the windings are synthesised so as to generate a periodic voltage having a rectangular waveform.

2. The induction generator having a pair of magnets of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 1, characterised in that:

said plurality of windings connected according to the predetermined configuration form first and second serial circuits;

said first serial circuit outputs a periodic first electromotive force having a rectangular waveform when a rotating magnetic field which causes electromagnetic induction in said even number of stator cores successively is created by said first, second, third and fourth magnets when said first and second single-opposed-polarity rotors are rotated; and

said second serial circuit outputs a periodic second electromotive force of a rectangular waveform 180^0 out of phase with the first electromotive force and having the same period as the first electromotive force, when a rotating magnetic field which causes electromagnetic induction in said even number of stator cores successively is created by said first and second single-opposed-polarity rotors are rotated.

3. The induction generator having a pair of magnets of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 2, further comprising:

rotation position detecting means for detecting a position of said first and second single-opposed-polarity rotors during their rotation; and

switching means which alternately causes positive components of said first electromotive force having a rectangular waveform and provided by said first serial circuit, or positive components of said second electromotive force having a rectangular waveform and provided by said second serial circuit to be output at intervals of an electrical angle of 180^0 to thereby produce a DC output.

4. The induction generator having a pair of magnets of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 1, characterised in that:

said plurality of windings comprise a first winding provided in a first stator core of said even number of stator cores, a second winding provided in a second stator core adjacent to the first stator core so as to wind in a direction opposite to a direction in which the first winding is provided, a third winding provided in a third stator core adjacent to the second stator core so as to wind in the same direction as the first winding, a fourth winding provided in a fourth stator core adjacent to the third stator core so as to wind in a direction opposite to a direction in which the third winding is provided, the first through fourth windings being connected with each other according to a predetermined configuration.

5. The induction generator having a pair of magnets of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 2, characterised in that:

said first serial circuit comprise a first winding provided to wind in a first direction in a first stator core of said even number of stator cores, a second winding serially connected to said first winding and provided in a second stator core adjacent to the first stator core so as to wind in a second direction opposite to the first direction, a third winding serially connected with said second winding and provided in a third stator core adjacent to the second stator core so as to wind in the first direction, a fourth winding serially connected to said third winding and provided in a fourth stator core adjacent to the third stator core so as to wind in the second direction; and

said second serial circuit comprises a fifth winding provided to wind in the second direction in said first stator core, a sixth winding serially connected to said fifth winding and provided in said second stator core so as to wind in said first direction, a seventh winding serially connected with said sixth winding and provided in said third stator core so as to wind in said second direction, an eighth winding serially connected to said seventh winding and provided in said fourth stator core so as to wind in said first direction.

6. The induction generator having a pair of magnets of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 1, characterised in that:

said first through fourth magnets are arc-shaped; and

said even number of stator cores have arc-shaped cross sections.

7. The induction generator having a pair of magnets of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 6, characterised in that said arc-shaped first through fourth magnets and said stator cores which have arc-shaped cross sections have an almost identical circumferential length.

8. The induction generator having a pair of magnets of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 2, characterised in that:

said first through fourth magnets are arc-shaped; and

said even number of stator cores have arc-shaped cross sections.

9. The induction generator having a pair of magnets of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 3, characterised in that:

said first through fourth magnets are arc-shaped; and

said even number of stator cores have arc-shaped cross sections.

10. The induction generator having a pair of magnets of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 4, characterised in that:

said first through fourth magnets are arc-shaped; and

said even number of stator cores have arc-shaped cross sections.

11. The induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 5, characterised in that:

said first through fourth magnets are arc-shaped; and

said even number of stator cores have arc-shaped cross sections.

12. The induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 8, characterised in that said arc-shaped first through fourth magnets and said stator cores which have arc-shaped cross sections have an almost identical circumferential length.

13. The induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 9, characterised in that said arc-shaped first through fourth magnets and said stator cores which have arc-shaped cross sections have an almost identical circumferential length.

14. The induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 10, characterised in that said arc-shaped first through fourth magnets and said stator cores which have arc-shaped cross sections have an almost identical circumferential length.

15. The induction generator having a pair of magnetic poles of the same polarity opposed to each other with respect to a rotation shaft as claimed in claim 11, characterised in that said arc-shaped first through fourth magnets and said stator cores which have arc-shaped cross sections have an almost identical circumferential length.

Patent Application EU 82,400,992.2   22nd December 1982   Inventor: Larry T. Jamison

ENERGY SOURCE EMPLOYING ELECTRICAL ENERGISER

This patent application shows the details of a device which it is claimed, can produce electricity without the need for any fuel. It should be noted that while construction details are provided which imply that the inventor constructed and tested several of these devices, this is only an application and not a granted patent.

ABSTRACT

An energy producing system is provided which produces energy for use, for example, in an electric vehicle or in a home power plant. The system includes an electrical energiser (**60**) including a double-wound rotor and a double-wound stator, for producing electrical energy which is stored in the system, e.g. in a battery (**66**) storage arrangement, which provides initial energisation of the system. the stored energy is supplied to an electric motor (**68**) which drives the energiser (**60**) to thereby create additional energy. the energiser is able to supply the needs of the system as well as to power a load.

BACKGROUND OF THE INVENTION

The present invention relates to energy producing systems and, more particularly, to an electrical energiser-motor system for providing energy, e.g., for an automotive vehicle or as part of a home energy plant.

With the advent of the so-called “energy crisis” and the consequent search for alternative energy sources to substitute for oil, considerable attention has been focused on automotive vehicles as chief users of oil products. One aspect of this search has fostered renewed interest in electrically driven vehicles such as electric cars and the like. A principal shortcoming of prior-art electrical vehicles has been the need to recharge the batteries which provide the power for the electrical motor drive system.

The present invention overcomes this problem through the provision of an electrical energiser-motor system which produces more energy than is expended, thereby enabling the excess energy to be stored in the battery system, to be drawn upon as required. Thus, the need for recharging of the batteries associated with conventional electrical vehicles is eliminated with the system of this invention. It should be noted that while the system of the invention has enormous potential in connection with its use in electrical vehicles, the system is clearly not limited to such use and would obviously be advantageous when used, for example, as the energy source for a home energy plant, as well as in many other applications.

In accordance with the invention, and energy producing system of the type described above is provided which comprises and electrical “energiser” comprising at least one double-wound stator and at least one double-wound shaft-mounted rotor located within a housing, electrical energy being collected from the rotor through a suitable electrical take-off device and being available for utilisation by the system, and an electric motor, powered by the energiser for driving the rotor shaft of the energiser. A battery arrangement is initially used to supply energy to the system and, as stated above, the excess energy generated by the energiser over and above that required by the system and the system load, is stored through charging of the batteries. The motor includes an armature with a plurality of winding slots in it and a plurality of windings being wound into two circumferentially spaced slots in the armature, i.e. such a winding is wound through a first slot (e.g. slot 1) and returned through a second spaced slot (e.g. slot 5). depending on the energy demands, the energiser may include a pair of stators and rotors, with the rotors being mounted on a common shaft. The motor is preferably energised through an arrangement of a commutator and plural brushes, while a slip ring and associated brushes connected to an output bridge circuit form the energy take-off for the energiser.

Other features and advantages of the invention will be shown in the detailed description of the preferred embodiments which follows.

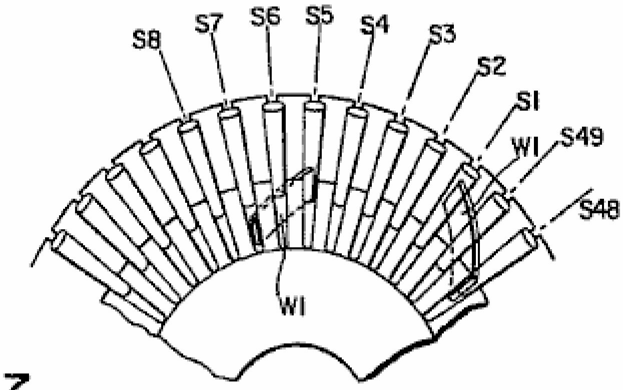

FIG. 7

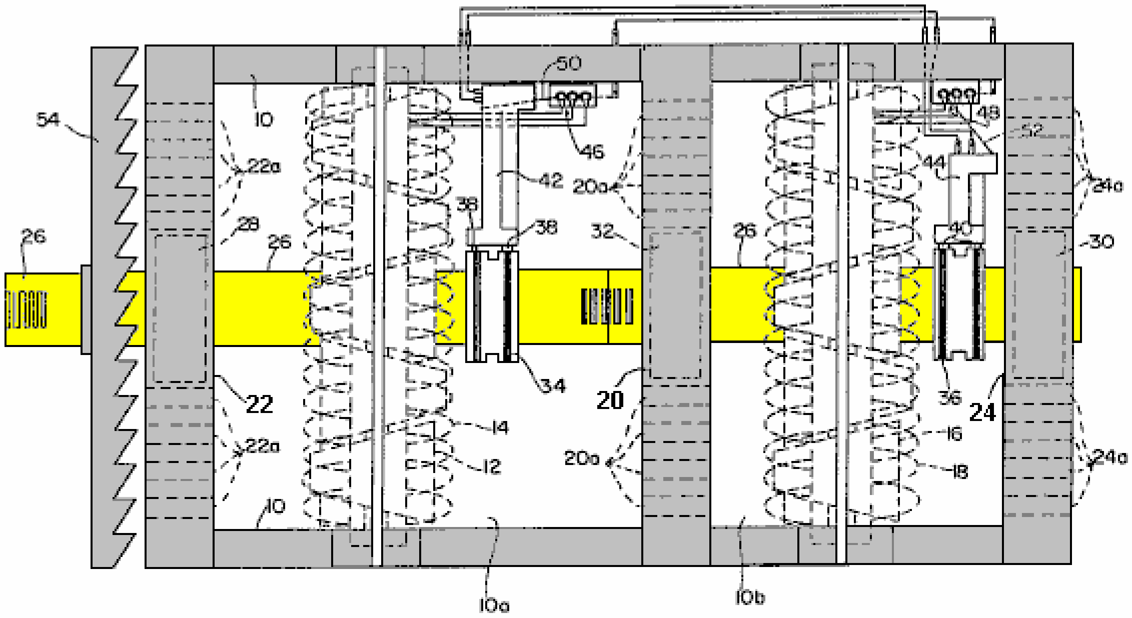

FIG. 1

Referring to **Fig.1**, a preferred embodiment of the “energiser” device of the invention is shown. The device includes a housing **10**, in which are located, in a first chamber or compartment **10a**, a first rotor **12** and a first stator **14** and, in a second compartment **10b**, a second rotor **16**, and a second stator **18**. It should be noted that although two stator-rotor combinations are used in this embodiment, a single stator-rotor combination can be used for some applications. Housing **10** is divided into the compartments **10a** and **10b**, by a centre plate **20** and it includes a pair of end plates **22** and **24**. Both the rotors **12**, **16** and the stators **14**, **18** are double wound and the rotors **12**, **16** are nested inside their respective stators **14** and **18** and mounted for rotation on a common shaft **26**. Shaft **26** extends longitudinally through housing **10** and is mounted on bearings **28** and **30**, supported by end plates **22** and **24**, and a further bearing **32** which is supported by central plate **20**.

A pair of slip rings **34** and **36**, are mounted on shaft **26** and connect with their corresponding brush pairs **38** and **40**.
Slip rings **34** and **36** are connected to rotors **12** and **16** respectively, and permit the current flowing in the rotor windings to be collected through the associated pairs of brushes **38** and **40**. Brush pairs **38** and **40** are mounted on respective brush holders **42** and **44**. The terminals of respective bridge circuits **46** and **48** are connected to stators **14** and **18**, while conversion bars 50 and 52 are connected to brush holders **42** and **44**, as indicated.

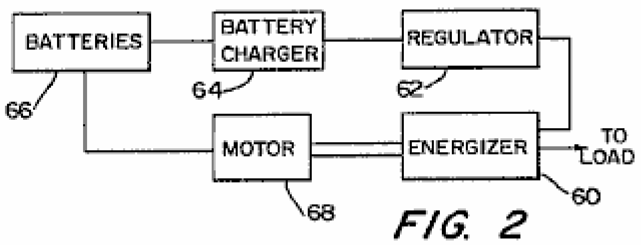

FIG. 2

A cooling fan **54**, is also mounted on shaft **26** and a plurality of apertures **201**, **22a** and **24a** are provided in centre plate **20** and end plates **22** and **24**, to promote cooling of the device. The energiser of **Fig.1** is preferably incorporated in a system such as shown in a highly schematic manner in **Fig.2** where the output of the energiser is used to supply the energy for driving a motor. To this end, the energiser, which is denoted by **60** in **Fig.2**, is connected through a regulator **62**, to battery charger **64** for batteries **66** connected to a motor **68**. These batteries **66** are used to provide the initial energisation of the system as well as to store energy produced by the energiser **60**. It will be understood that the energiser **60** provides energy enough to power motor **68** (which, in turn, drives energiser **60** through rotation of shaft **26**) as well as to provide storage for energy in the system. It will also be appreciated that the system illustrated schematically in **Fig.2** includes suitable controls (switches, rheostats, sensors, etc.) to provide initial energisation as well as appropriate operational control of the system.

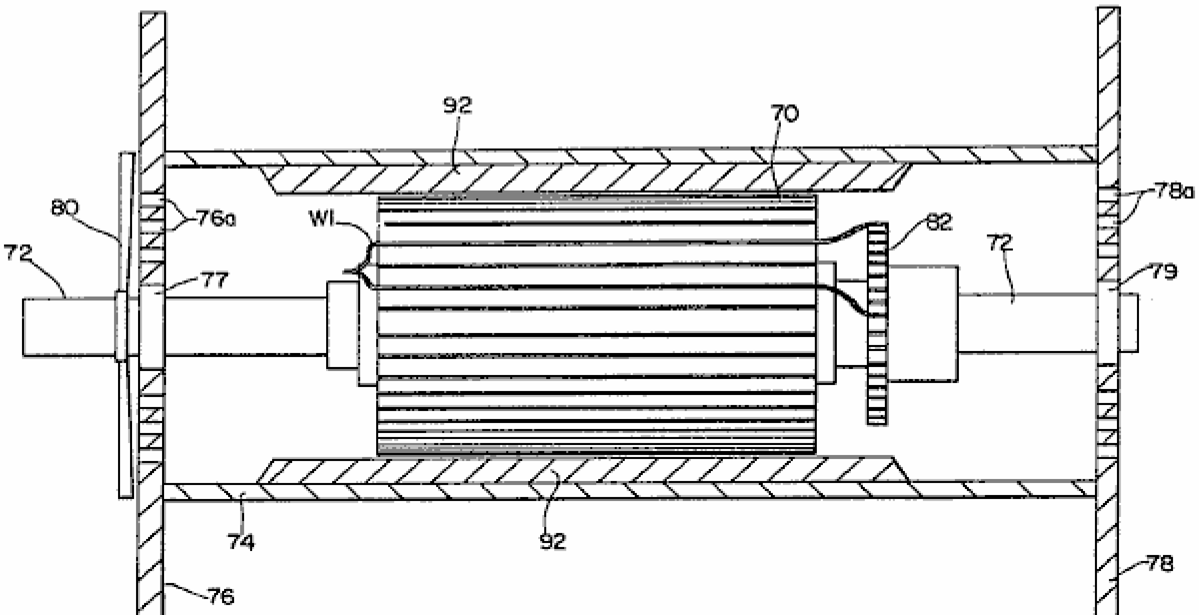

FIG. 3

In a preferred embodiment, motor **68** is of the form shown in **Fig.3**. As illustrated, the motor is of a generally conventional form (with exceptions noted below) and comprises an armature **70**, mounted on a shaft **72** within housing **74**. Housing **74** includes a pair of end plates **76** and **78**, which mount shaft bearings **77** and **79**. Apertures **76a** and **78a** are provided in end plates **76** and **78** and a cooling fan **80** is mounted on shaft **72** to provide cooling.

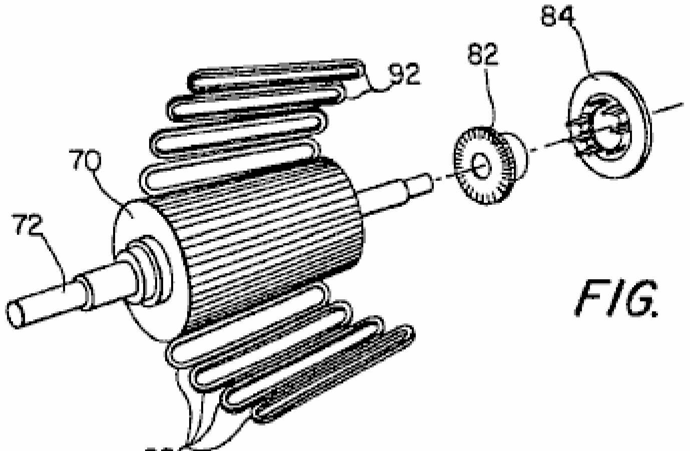

FIG. 4

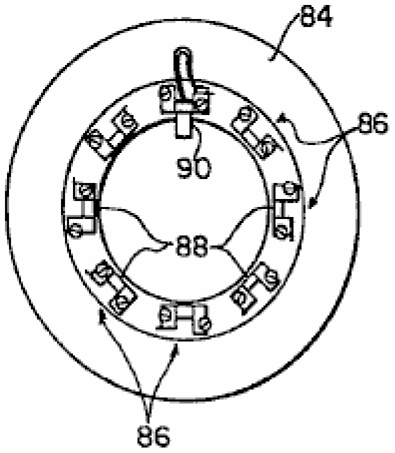
A commutator **82** is also mounted on shaft **72**, and co-operates with associated brushes (not shown in **Fig.1**), to conduct current to the windings of armature **70**. This co-operation is shown best in **Fig.4** which is an exploded view, illustrating the armature **70**, commutator **82** and a brush holder **84**.

FIG. 5



As shown in **Fig.5**, the brush holder **84** includes eight brush mounts **86**, each of which defines a slot **88** in which a pair of brushes is mounted. One brush **90** is shown in **Fig.5**, it being understood that two such brushes are mounted in each slot **88** so that sixteen brushes are required.

The motor of **Fig.3** to **Fig.6** includes eight pole shoes (not shown) which are secured to housing **74** and which serve to mount eight field coils or windings **92** (see **Fig.3** and **Fig.4**) spaced out around the periphery of armature **72**.

An important feature of the motor of **Fig.3** to **Fig.6** concerns the manner in which the windings for armature **70** are wound. As illustrated in **Fig.3**, **Fig.6** and **Fig.7**, a typical winding **W1** is wound in two slots, with the illustrated winding being doubled back and continuing from armature slot **S1** to armature slot **S5** (see **Fig.3** and **Fig.6**). Similarly, the winding in slot **S2** continues to slot **S6**, the winding of slot **S3** continues to slot **S7**, and so on for the forty-nine windings.

In a specific preferred embodiment, the motor described above is a 48-volt, 412 horsepower motor having a top operating speed of 7,000 rpm. A rheostat control (not shown) is used to control the input voltage and, as discussed above, the motor is powered from the energiser of **Fig.1**. It will be appreciated that the energy take-off from the system is preferably from the output shaft of the motor, although the electrical energy may also be tapped off from the energiser output.

Although the invention has been described in relation to exemplary embodiments, it will be understood by those skilled in the art, that variations and modifications can be effected in these embodiments without departing from the scope and spirit of the invention.

CLAIMS

1. An energy-producing system providing an output for utilisation by a utilising device, the system comprising:

An electrical energising means comprising a housing (**10**); at least one double-wound stator (**14** or **18**) located within the housing; at least one double-wound rotor (**12** or **16**) located within the housing; a rotor shaft (**26**), supported in the housing, and on which the double-wound rotor is mounted; and an energy take-off mechanism (**34** or **36**) including a mechanism for collecting electrical energy from the rotor, mounted on the shaft and connected to the rotor, the mechanism having at least one stationary output.

A motor (**68**), including a connection to the electrical energiser through which to draw the power to operate the motor and drive the rotor shaft of the energiser, the motor having an armature (**70**) with a plurality of winding slots (**S1** to **S49**) in it, and a plurality of windings (**W1**) wound in those slots, at least some of the windings being wound in two slots spaced out around the circumference of the armature (for example, **S1** and **S5**), and an energy supply mechanism (**66**) for supplying electrical energy to the motor at least during initial energisation of the motor, and connected to the energiser for supplying energy to the motor during its operation.

2. A system as in Claim 1, where the energiser includes a pair of these rotors (**12**, **16**) and a pair of stators (**14**, **18**), the rotors being mounted on a common shaft (**26**).

3. A system as in Claim 1, where the energy take-off includes a slip ring (**34** or **36**) and at least one brush (**38** or **40**) for collecting electrical current from the rotor windings, the brush being connected to a bridge circuit (**46** or **48**).

4. A system as in Claim 1, where the motor contains a commutator (**82**) through which energy is supplied to the armature windings.

5. A system as in Claim 4, where the same winding (W1) is wound in the first and fifth slot positions of the motor armature, and the ends of that winding are connected to two positions spaced out around the circumference of the commutator (see **Fig.3**).

United States Patent 5,436,518 25th July 1995 Inventor: Teruo Kawai

MOTIVE POWER-GENERATING DEVICE

Please note that this is a re-worded excerpt from this patent. It describes a motor which has an output power greater than its input power.

SUMMARY OF THE INVENTION

It is an object of the invention to provide a motive power generation device in which the occurrence of a force acting in a direction opposite to the direction of movement of a rotor and/or a stator is prevented, so as to permit efficient use of electric energy to be applied to electromagnets, as well as magnetic energy generated by a permanent magnet.

In order to achieve the above object, the first invention comprises a permanent magnet disposed around a rotational output shaft which is mounted on a bearing, a magnetic body positioned concentrically with the permanent magnet for rotation with the output shaft, the magnetic body being subjected to the magnetic flux of the permanent magnet, a plurality of electromagnets permanently mounted on the support member so that they are spaced a predetermined distance around the periphery of the magnetic material, each magnetic circuit of the electromagnets being independent of one another and the excitation change-over mechanism of the electromagnets which can sequentially magnetise one of the electromagnets which is positioned forward, with regard to a rotational direction, of the output shaft, so as to impart to the electromagnet a magnetic polarity magnetically opposite to that of the magnetic pole of the permanent magnet, whereby a magnetic flux passing through the magnetic body converges in one direction thereby applying a rotational torque to the output shaft.

According to the first invention, when one of the electromagnets which is positioned ahead in the rotational direction of the rotational output shaft, a magnetic field created by the excited electromagnet and a magnetic field created by the permanent magnet interact with each other. Thus, the magnetic flux passing through the magnetic body converges toward the exited electromagnet, so as to rotate the rotational output shaft by a predetermined angle toward the excited electromagnet. When the rotational output shaft has been rotated by the predetermined angle, the above excited electromagnet is de-magnetised, and another electromagnet currently positioned ahead with respect to the rotational direction of the rotor output shaft is excited or magnetised. Sequential excitation of the electromagnets in the above manner permits rotation of the output shaft in a predetermined direction. In this regard, it should be noted that the electromagnets are excited so as to have a magnetic polarity opposite to that of the magnetic pole of the permanent magnet and that the magnetic circuit of the excited electromagnets is independent from those of adjacent electromagnets. Thus, the magnetic flux generated by the excited electromagnet is prevented from passing through magnetic circuits of adjacent electromagnets, which, if it occurs, might cause the electromagnets to be magnetised to have the same polarity as that of the magnetic pole of the permanent magnet. Accordingly, no objectionable force will be generated which might interfere with rotation of the output shaft.

In order to achieve the above object, the second invention comprises a permanent magnet mounted on a movable body arranged movably along a linear track, a magnetic body mounted on the permanent magnet, the magnetic body being subjected to a magnetic flux of the permanent magnet, a plurality of electromagnets spaced an appropriate distance along the linear track, the electromagnets having magnetic circuits which are independent of one another and the excitation mechanism arranged to magnetise each of the electromagnets sequentially when each is positioned forward of the movable body, (with respect to the direction of movement) so as to impart to the excited electromagnet a magnetic polarity opposite to that of the magnetic pole of the permanent magnet, whereby a magnetic flux passing through the magnetic body converges in a predetermined direction so as to cause linear movement of the movable body.

According to the second invention, when the electromagnet positioned ahead of the forward end of the movable body with regard to the direction of the movement of the movable body is excited, a magnetic field generated by the excited electromagnet and magnetic field generated by the permanent magnet interact with each other. Thus, a magnetic flux passing through the magnetic body converges toward the excited electromagnet, so as to displace the movable body a predetermined distance toward the excited electromagnet. When the movable body has been moved the predetermined distance, the movable body is positioned below the above excited electromagnet, and another electromagnet is positioned ahead of the forward end of the movable body. When this occurs, excitation of the electromagnet positioned above the movable body is interrupted, and excitation of the electromagnet now positioned ahead of the forward end of the movable body is initiated. Sequential excitation of the electromagnets in the above manner permits movement of the movable body in a predetermined direction It should be noted that no objectionable force which would interfere with movement of the movable body is created for the same reason as that explained in relation to the first invention.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Preferred embodiments of the invention will be explained in detail below with reference to the attached drawings.

According to a first embodiment of the invention, a rotational output shaft **11** is mounted in a bearing between front and rear side plates **10a** of a support member **10** through bearings **11a**, as shown in **Fig.1** and **Fig.2**. A ring of permanent magnets **13** are fitted over the opposite ends of the output shaft, inside the side plates **10a** and these move with the rotor shaft **11**. The permanent magnets are magnetised in the axial direction. A magnetic body **14** is rigidly mounted between each of the side plates **10a** of the rotor shaft **11** and the permanent magnets **13**. Each of these magnetic bodies **14** has alternate notches **14a** and magnetic teeth **14b**. It should be noted that the flux of the permanent magnets **13** passes through the respective magnetic bodies **14**. For example, **Fig.1** shows the magnetic body **14** with three notches **14a** and three magnetic teeth **14b**. The permanent magnets **13** and magnetic bodies **14** are positioned co-axially with the rotor output shaft **11**. The corresponding permanent magnets **13** and magnetic bodies **14** are shown connected together by bolts **15** so as to form a rotor **12** which is attached to the rotational output shaft **11**.

It should be noted that the support member **10** and rotational output shaft are both made from a non-magnetic material. The support member **10** may be formed, for example, from stainless steel, aluminium alloys, or synthetic resins, while the rotational output shaft **11** may be formed from stainless steel, for example. Thus, the magnetic circuit formed by the permanent magnet **13** and magnetic body at one axial end of the rotational output shaft **11** and the magnetic circuit formed by the permanent magnet **13** and magnetic body at the opposite axial end of the output shaft, are independent of one another. The magnetic bodies **14** may be formed from magnetic materials having a high magnetic permeability, such as various kinds of steel materials, silicon steel plate, permalloys, or the like.

The stator contains electromagnets **16a** through **16l**, which are positioned between the side plates **10a**. The electromagnets are evenly spaced around the magnetic pieces **14** so that they surround the magnetic bodies. As shown in **Fig.1**, twelve electromagnets may be used. The magnetic circuit of each of the electromagnets **16a** through **16l** is arranged so as to be independent of each other, so that no flux of a magnetised electromagnet passes through the iron cores of the adjacent electromagnets.

The iron cores of the electromagnets **16a** through **16l** are positioned parallel to the rotor axis shaft **11**, and positioned with only a slight gap between them and the magnetic bodies **14**.

Some of the electromagnets **16a** through **16l** are located at a position corresponding to boundary portions **14c1** through **14c6** between the notch **14a** and the magnetic tooth **14b**. For example, as shown in **Fig.1**, electromagnets **16a, 16b, 16e, 16f, 16i** and **16j** are positioned opposite the boundary portions **14c1, 14c2, 14c3, 14c4, 14c5,** and **14c6**, respectively.

Fig.5A shows a path of magnetic flux created by the permanent magnet **13** when the electromagnets are not excited or magnetised, while, **Fig.5B** shows a path of magnetic flux created by the permanent magnet **13** and a path of magnetic flux created by the windings of the electromagnets when the electromagnets are magnetised. As will be clear from **Fig.5A** and **Fig.5B**, both paths of magnetic flux represent a uni-polar distribution in which N-pole or S-pole evenly appears at the opposite axial ends. When the electromagnets are magnetised, the magnetic fields of the permanent magnet and electromagnets co-operate or interact with each other so as to generate a rotational torque.

Excitation change-over mechanism **17** for sequentially exciting or magnetising the electromagnets **16a** through **16l** is basically consisted of a conventional excitation circuit for supplying direct current to each windings of the electromagnets **16a** through **16l**. In this embodiment, the change-over portion for changing electric feed to the electromagnets **16a** through **16l** includes a plurality of optical sensors **18** and a light shield plate **19** for turning the optical sensors ON and OFF as shown in **Fig.6**.

The optical sensors **18** are spaced apart from one another with a space between them for permitting the light shield plate **19** to pass through a light emitting element and a light receiving element. The optical sensors **18** are disposed in the outer surface of one of the side plates **10a** equally spaced apart along the circumference, so that they are positioned to correspond to the electromagnets **16a** through **16l** (for example, the optical sensor **18** is shown to be disposed in the outer surface of the rear side plate). The light shielding plate **19** is fixed to the rotational output shaft **11** at the end thereof, the light shielding plate protruding from the rear side plate **10a** on which the optical sensors are mounted.

According to the illustrated embodiment, when a particular optical sensor **18** is blocked by the light shielding plate **19**, the electromagnet corresponding to such optical sensor **18** is supplied with electricity.

The operation of the first embodiment described above will be explained with reference to **Fig.4A** through **Fig.4H**.

When the electromagnets **16a** through **16l** are not supplied with electricity by means of the excitation changeover mechanism **17**, the electromagnets **16c, 16d, 16g, 16h, 16k** and **16l** opposed to the magnetic teeth **14b** with a small gap between them merely serve as a magnetic material disposed within the magnetic field of the permanent magnet **13** (refer to shaded portion in **Fig.4A**), so as to absorb the magnetic teeth **14b**, and the rotor **12** remains stationary.

When the electromagnets **16a, 16e** and **16i** positioned adjacent to the boundary portion **14c1, 14c3** and **14c5** formed between the respective notches **14a** and the magnetic teeth **14b** are magnetised or excited simultaneously by means of the excitation change-over mechanism, as shown in **Fig.4B**, the magnetic field of the permanent magnet **13** and the magnetic fields of the electromagnets **16a, 16e** and **16i** interact with each other, so that a magnetic flux **14d** passing through the magnetic body **14** instantaneously converges to the electromagnets **16a, 16e,** and **16i**. In this way, the rotor **12** is imparted with a rotational torque in a direction in which the magnetic flux **14d** will be widened, i.e., counterclockwise direction as viewed in **Fig.4B**.

Fig.4C through **Fig.4G** illustrate change in the width of the magnetic flux **14d** in accordance with rotation of the rotor **12**. When the width of the magnetic flux becomes maximised, i.e., when only the magnetic teeth **14b** are opposed to the electromagnets **16a, 16e** and **16i**, while the notches **14a** are displaced completely away from the electromagnets **16a, 16e** and **16i**, the width of the magnetic flux **14d** is maximised. Thus, an absorption force acting between the permanent magnet **13** and the electromagnets **16a, 16e** and **16i** is maximised. On the other hand, the rotational torque acting on the rotor **12** becomes zero.

Before the rotational torque acting on the rotor **12** becomes zero, i.e., as the boundary portion **14c1, 14c3** and **14c5** approach another electromagnets **16b, 16f** and **16j** positioned ahead of (with regard to the rotational direction), respectively, the electromagnets **16a, 16e** and **16i** are demagnetised and the electromagnets **16b, 16f** and **16j** are excited or magnetised by means of the excitation change-over mechanism **17**. Thus, the magnetic flux **14d** converges toward the electromagnets **16b, 16f** and **16j**, as shown in **Fig.4H**, so that a rotational torque acts upon the rotor, as described above.

Then, the electromagnets **16c, 16g** and **16k** are excited. When the boundary portion **14c1, 14c3** and **14c5** approach another electromagnets **16d, 16h** and **16l** positioned ahead with respect to the rotational direction, in response to rotation of the rotor **12**, the electromagnets **16c, 16g** and **16k** are de-magnetised and the electromagnets **16d, 16h** and **16l** are energised or excited.

As explained above, sequential excitation or energising of the electromagnets **16a** through **16l** causes interaction between the magnetic flux of the permanent magnet **13** and the electromagnets **16a** through **16l**, whereby a rotational torque is applied to the rotor **12**.

When this occurs, a rotational torque is generated between one of the magnetic poles of the permanent magnet **13** (for example, N-pole) and the magnetic poles (for example, S-poles) of the electromagnets **16a** through **16l** positioned at their respective axial ends. A rotational torque is also generated between the other magnetic pole (for example, S-pole) of the permanent magnet **13** and the other magnetic pole (for example, N-pole) of each of the electromagnets **16a** through **16l** positioned at the other axial end.

It should be noted that, at one magnetic pole, for example N-pole, of the permanent magnet **13**, certain of the electromagnets **16a** through **16l** are magnetised only to S-pole, thus preventing formation of a magnetic circuit, due to passage of magnetic flux from the excited electromagnets through either of the adjacent electromagnets, which tends to bring about N-poles magnetically similar to the permanent magnet **13**. It is also noted that, at the other magnetic pole, for example S-pole, of the permanent magnet **13**, certain of the electromagnets are magnetised only to N-pole, thus preventing formation of a magnetic circuit, due to passage of magnetic flux from the excited electromagnets through adjacent electromagnets, which tends to bring about S-poles magnetically similar to the permanent magnet **13**. The magnetic flux of the permanent magnet **13** passes through the magnetic bodies **14** so as to be converged to the excited electromagnets (refer to the magnetic flux **14d** shown in **Fig.4** through **Fig.4H**), thus forming dead zones, through which no magnetic flux passes, in the magnetic bodies **14** at a position opposite to the un-excited electromagnets. Accordingly, no force is generated which would tend to prevent rotation of the rotor **12**.

In view of electric energy applied to the electromagnets **16a** through **16l**, substantially all the electric energy applied is used to contribute to the rotation of the rotor **12**. On the other hand, and in view of magnetic energy of the permanent magnet **18**, all the magnetic energy contributes to the rotation of the rotor **12**.

It is also noted that, since the notches **14a** and the magnetic teeth **14b** are alternately disposed in the outer periphery of the magnetic materials **14** in an acute angle configuration seen in **Fig.4A** to **Fig.4H**, and the electromagnets are disposed at a position each corresponding to the boundary portions between the notches and the magnetic teeth, it is possible for the line of the magnetic force, generated in each gap between the boundary portions and the electromagnets when the electromagnets are excited, to be inclined to a substantial degree, so that a sufficient degree of rotational torque may be obtained upon initial excitation of the electromagnets.

The result obtained during an actual running test of the motor according to the first embodiment is shown in **Fig.1** to **Fig.3**.

Pure steel was used as a magnetic material. The magnetic material was 30 mm in thickness and formed to have magnetic teeth of 218 mm diameter and notches of 158 mm diameter. A ferrite magnet was used as a permanent magnet. The magnetic force of the magnet was 1,000 gauss. Electric power of 19.55 watts was applied to the electromagnets at 17 volts and 1.15 amperes. The above conditions produced a rotational speed of 100 rpm, with a torque of 60.52 Kg-cm and an output of 62.16 watts.

Alternative embodiments will be explained below with reference to **Fig.6** through **Fig.9**.

The modified embodiment shown in **Fig.6** is similar to the motor presented as the first embodiment as shown in **Fig.1** through **Fig.3**, with the exception that each electromagnet **160** used as part of the stator, comprises an iron core **161** having a pair of legs **162** which extend towards the outer periphery of the magnetic bodies (outer periphery of the magnetic teeth **14b**), each of the legs being wound with coils **163**. The remaining components are basically identical to those in the motor shown in **Fig.1** through **Fig.3**. In **Fig.6**, the components similar to those in **Fig.1** through **Fig.6** are denoted by like reference numerals. It should be noted that each coil **163** is supplied with electricity so that one leg **162** (left-hand side in **Fig.6**) of each of the iron cores **161** is magnetised to be S-pole which is magnetically opposite to the magnetic pole (N-pole) of the confronting magnetic body **14**, while the leg **162** disposed at the other end of each of the iron cores is magnetised to be N-pole which is magnetically opposite to the magnetic pole (S-pole) of the confronting magnetic body **14**.

According to this modified embodiment, it is possible to significantly reduce leakage of the magnetic flux created by the electromagnets **160** in gaps each defined between the surfaces of the magnetic poles of the electromagnets **160** and the outer peripheries of the magnetic teeth **14b** of the magnetic bodies **14**.

An alternative embodiment shown in **Fig.7** is similar to the motor shown in **Fig.1** through **Fig.8**, with the exception that: an additional magnetic body **14** is mounted on the rotational output shaft **11** at it's axial midpoint; two permanent magnets **130** are freely mounted on the output shaft **11** in the manner shown in **Fig.6**; and each iron core **165** is provided with three legs **166** positioned at the opposite axial ends and midpoint thereof and extending toward the respective outer periphery of the magnetic bodies, with the legs **166** positioned at axial opposite ends of the respective iron cores **165** being wound with a coil **167**, which form electromagnets **164**. The remaining components are substantially the same as those in the motor shown in **Fig.1** through **Fig.3**. It should be noted here, that the rotational output shaft **11** may be formed from either magnetic materials or non-magnetic materials.

As shown in **Fig.7**, each of the coils **167** is supplied with electricity so that the legs **166** positioned at the opposite axial ends of each of the iron cores **164** is magnetised to be S-pole which is magnetically opposite to the magnetic pole (N-pole) of the confronting magnetic body **14**. By this, the leg **166** positioned at the midpoint of the iron core **165** is magnetised to be N-pole which is magnetically opposite to the magnetic pole (S-pole) of the confronting magnetic body **14**.

In this embodiment, it is also possible, as in the modified embodiment shown in **Fig.6**, to significantly reduce the leakage of the magnetic flux generated by the electromagnets **164**. In addition to this, it is also possible to obtain a rotational torque between the leg **166** positioned at the midpoint of the iron core and the magnetic body **14** positioned at the axial midpoint of the rotational output shaft **11**. Accordingly, a higher rotational torque may be obtained with the same amount of electrical consumption, in comparison with the embodiment shown in **Fig.6**.

A further embodiment shown in **Fig.8** is similar to the motor shown in **Fig.1** though **Fig.3**, with the exception that a permanent magnet magnetised in the radial direction, rather than in the axial direction is employed. The permanent magnet **131** of an annular configuration has, for example, N-pole in the outer periphery and S-pole in the inner periphery. The permanent magnet **131** is received within a cavity **14e** provided in the respective magnetic body **14** at the intermediate portion thereof as disposed at the opposite axial ends of the rotational output shaft **11**. The remaining components are identical to those in the motor shown in **Fig.1** though **Fig.3**. The components identical to those in the motor shown in **Fig.1** though **Fig.3** are denoted by the same reference numerals. It should be noted that this embodiment may also employ the electromagnets **160** shown in **Fig.6**.

In this embodiment, the rotational output shaft **11** may be formed from magnetic materials, rather than non-magnetic materials.

Further embodiment shown in **Fig.9** is similar to the motor shown in **Fig.1** though **Fig.3**, with three exceptions. The first exception is that a permanent magnet magnetised in the radial direction, rather than in the axial direction is employed. The permanent magnet **131** having an annular configuration has, for example, N-pole in the outer periphery and S-pole in the inner periphery. The permanent magnet **131** is received within a cavity **14e** provided in the respective magnetic body **14** at the intermediate portion thereof as disposed at the axial opposite ends of the rotational output shaft **11**. The second exception is that an additional magnetic body **14** is disposed at the axial midpoint of the rotational output shaft **11**. Finally, the third exception is that the iron core **165** is provided with three legs **166** disposed at the axial opposite ends and the midpoint thereof, respectively, and extending toward the outer periphery of the magnetic body **14**, with the legs positioned at the opposite axial ends being wound with respective coils so as to form an electromagnet **164**. The remaining components are identical to those in the motor shown in **Fig.1** though **Fig.3**. The components identical to those in the motor shown in **Fig.1** though **Fig.3** are denoted by the same reference numerals.

As shown in **Fig.9**, each coil is supplied with electricity so that the legs **166** disposed at opposite axial ends of the iron core **165** are magnetised to be S-pole which is magnetically opposite to the magnetic pole (N-pole) of the confronting magnetic body **14**. By this, the leg **166** disposed at the midpoint of the iron core **165** is magnetised to be N-pole which is magnetically opposite to the magnetic pole (S-pole) of the confronting magnetic body **14**.

According to the embodiment described above, the rotational output shaft **11** may be formed from magnetic materials rather than non-magnetic materials. With this embodiment, it is possible to obtain the same effect as that obtained with the embodiment shown in **Fig.7**.

Further the alternative embodiments shown in **Fig.10A** to **Fig.10C** are similar to the motor shown in **Fig.1** though **Fig.3**, with the exception that: like the embodiments shown in **Fig.8** and **Fig.9**, an annular permanent magnet **131** is employed which is received in a cavity **140e** provided in the central portion **140** of the magnetic body **140**; the magnetic body **140** is provided with notches **140a** in the outer peripheral portion thereof, so that the gap G between the magnetic body **140** and the electromagnet becomes gradually broader in the rotational direction of the rotor; and the electromagnets confronting to the gap G with an intermediate width as positioned between the electromagnets confronting to the gap G with a narrower width and the electromagnets confronting to the gap G with a broader width are excited or magnetised in a sequential manner. The remaining components are identical to those in the motor shown in **Fig.1** though **Fig.3**. In **Fig.10A** to **Fig.10C**, the components identical to those in **Fig.1** though **Fig.3** are denoted by the same reference numerals. In this regard, it should be noted that reference numeral **140d** indicates magnetic flux passing through the magnetic body **140**, so as to illustrate converged condition of such magnetic flux upon excitation of the electromagnets.

In the embodiment Just described above, it is possible to rotate the rotor in the counter clockwise direction as viewed in **Fig.10A**, for example, by exciting the electromagnets **16a, 16d, 16g** and **16j**, as shown in **Fig.10A**, then, the electromagnets **16c, 16f, 16i** and **16l**, as shown in **Fig.10B**, and then the electromagnets **16b, 16e, 16h** and **16k**. According to this embodiment, it is possible to obtain a stable rotational force, as well as a higher rotational torque, even though number of rotations is reduced in comparison with the above embodiment.

As shown in **Fig.10A**, four notches **140a** are provided. It should be noted, however, that two or three notches may be provided. It is also possible to attach the magnetic material **140** to the rotational output shaft **11** in an eccentric manner in its entirety, without providing notches **140a.**

Fig.11A through **Fig.11H** are illustrative diagrams showing the operation of the second embodiment of the invention when developed into a linear motor type.

According to this embodiment, a movable body **21** is adapted to be moved along a linear track **20** of a roller conveyor type. The track includes a frame on which a plurality of rollers are positioned in parallel relative to one another. A permanent magnet **22** is mounted on the movable body **21**. A magnetic body **23** of a plate-like configuration is fixed to the permanent magnet **22** in the upper surface, so as to form a movable element. It should be noted that magnetic flux from the permanent magnet **22** passes through the magnetic body **23**. A plurality of electromagnets **25a, 25b, 25c, 25d** and so on are disposed above the movable element **24** along the linear track positioned parallel to each other. These electromagnets constitute a stator **25**. Magnetic circuits of the electromagnets **25a, 25b, 25c, 25d**, and so on, are independent from one another, so that the electromagnets are magnetised in a sequential manner by means of excitation change-over mechanism (not shown), so as to have a magnetic polarity opposite to the magnetic pole of the permanent magnet **22**. Power output shafts **21a** are attached to a side surface of the movable body **21**.

Operation of the above second embodiment will be explained below.

As shown in **Fig.11A**, and when no electricity is supplied to the electromagnets, the electromagnets **25a** and **25b** positioned Just above the movable element **24** are subjected to magnetic field of the permanent magnet **22** (refer to shaded portion in **Fig.11A**). Thus, such electromagnets magnetically absorb the magnetic body **23**, so that the movable element **24** remains to be stopped.

As shown in **Fig.11B**, and when the electromagnet **25c**, positioned ahead with respect to the direction in which the movable element **24** moves, is excited, the magnetic field of the permanent magnet **22** and the magnetic field of the electromagnet **25c** interact with each other, so that magnetic flux **23a** passing through the magnetic body **23** converges instantaneously toward the electromagnet **25c**. By this, the movable element **24** is magnetically absorbed to the electromagnet **25c**, so that it is moved along the linear track **20** under the propulsive force acting in the direction in which the width of the magnetic flux **23a** becomes broader, i.e., in the direction of an arrow mark shown in **Fig.11B**.

Fig.11C through **Fig.11E** illustrate a change in width of the magnetic flux **23a** in response to movement of the movable element **24**. At the point at which the width of the magnetic flux **23a** becomes maximised, i.e., when the forward end of the magnetic material **23** of the movable element **24** is positioned just before passing by the electromagnet **25c**, the width of the flux **23** becomes maximised. At this time, magnetic absorption acting between the permanent magnet **22** and the electromagnet **25c** becomes maximised, but the propulsive force acting on the movable element becomes zero.

Before the propulsive force acting on the movable element **24** becomes completely zero, i.e., when the forward end of the magnetic body **23** of the movable element **24** is about to pass the electromagnet **25d**, the excitation changeover mechanism is actuated so as to stop excitation of the electromagnet **25c** and so as to initiate excitation of the electromagnet **25d**. Thus, the magnetic flux **23a** converges to the electromagnet **25d**, as shown in **Fig.11F**, so that a propulsive force acts on the movable element **24**, as in the previous stage.

Subsequently, and in response to further movement of the movable element **24**, the width of the magnetic flux **23a** is reduced as shown in **Fig.11G** and **Fig.11H**, and thus a similar operation will be repeated.

The sequential excitation of the electromagnets, as explained above, causes interaction between the magnetic fields of permanent magnet **22** and electromagnets, whereby a propulsive force is applied to the movable element **24**.

It should be noted that, when the magnetic polarity of the permanent magnet **22** confronting the electromagnets is assumed to be N-pole, the electromagnet **25c** is magnetised solely to be S-pole, so as to prevent formation of a magnetic circuit by virtue of passage of magnetic flux from the electromagnet **25c** through to the adjacent electromagnets **25b** and **25d**, which formation, if it occurs, tends to cause the polarity of the electromagnets to be N-pole identical to the magnetic pole of the permanent magnet **22**. Accordingly, and in a manner similar to that in the first embodiment, no force is generated which tends to interfere with movement of the movable element **24**.

In the present invention, a plurality of electromagnets serving as a stator are so arranged that their respective magnetic circuits become independent from one another. The electromagnets are also arranged so that they are solely magnetised or excited to have a magnetic polarity opposite to the magnetic pole of the confronting permanent magnet. Thus, each electromagnet is prevented from becoming magnetised to the same polarity as that of the permanent magnet, which may occur when magnetic flux from a particular electromagnet passes through to adjacent electromagnets. Accordingly, no force will be exerted which tends to interfere with the intended movement of a rotor or a movable element. As a result, electric energy applied to the electromagnets may be efficiently utilised, while, at the same time, magnetic energy contained in the permanent magnet may-also be efficiently utilised.

The coils constituting the electromagnets are consistently supplied with electric current with the same polarity, without any change, so that heating of coils may be prevented. Further, it is possible to obviate the problems of vibration and noise which might occur due to a repulsive force being generated when polarity of an electric current supplied to the coils is changed.

JOSEPH NEWMAN: ENERGY GENERATOR

Patent WO8300963 17th March 1983 Inventor: Joseph W. Newman

ENERGY GENERATION SYSTEM HAVING HIGHER ENERGY OUTPUT THAN INPUT

This patent covers a device which is claimed to have a greater output power than the input power required to run it.

ABSTRACT

A system for generating obvious work motion, or electromagnetic energy (fields of force) or electric current utilising the electromagnetic energy which makes up a matter and results in a greater output of energy, than the initial input of conventional energy means and teachings. A first exemplary embodiment (**Fig.1**) of the generator uses a contained fluid (**117**) surrounding a series of aligned magnets (**120**); while a second exemplary embodiment (**Fig.3**) uses a special material (**201**) held stationary between two static magnets (**202**, **203**), the special material having its atoms aligned but maintaining the resulting magnetic field at least substantially within its boundary surface; while third and fourth exemplary embodiments (**Fig.5** and **Fig.6**) utilise a relatively heavy coil (**205**) made up of relatively large diameter wire of relatively great length and number of loops and length and a relatively small energising current to drive a rotatable permanent magnet (**200**).

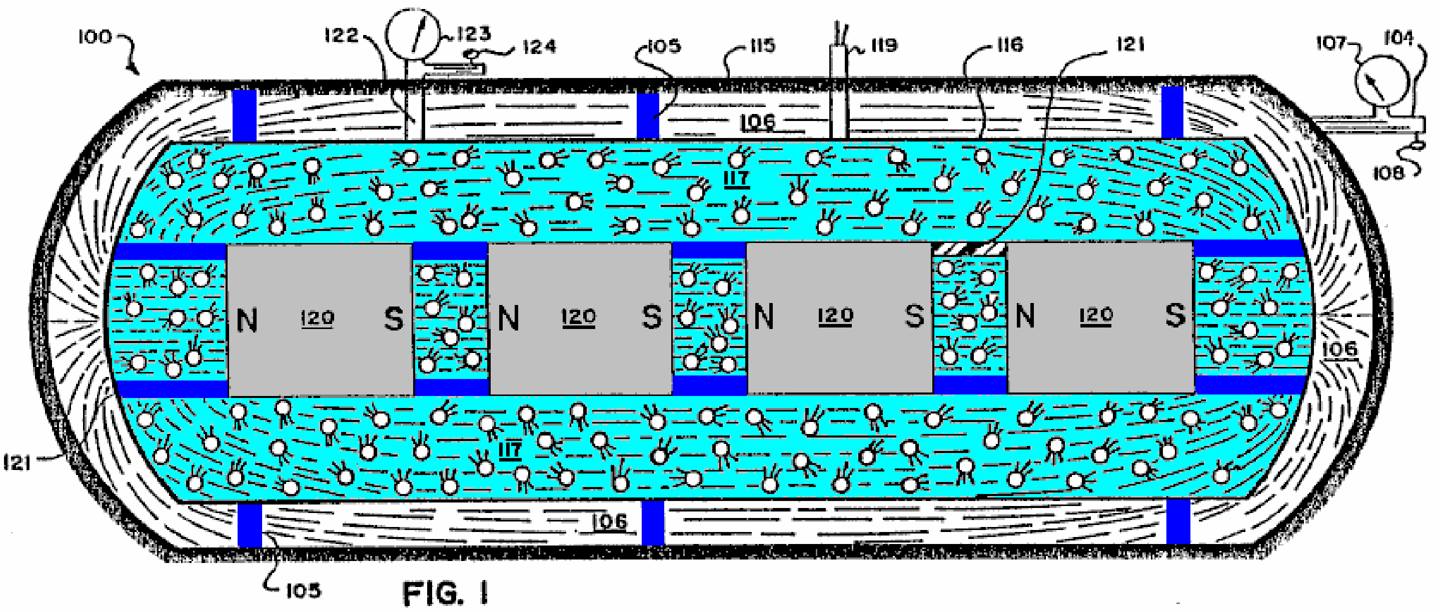

FIG. 1

DESCRIPTION

BACKGROUND OF THE INVENTION

1. Field of the Invention:

The present invention relates generally to devices or systems (including methods) for generating usable energy such as for example electrical energy from electromagnetic fields, electrical energy or electromagnetic fields from matter, and more particularly to devices or systems (including methods) for producing electrical current flow for use as electrical power, and magnetic fields of force which cause motion (obvious work) or electrical current flow or for increasing electromagnetic potential energy available for use or mechanical energy available for use.

2. Prior Art:

There have been many devices proposed over the years for producing electrical-energy, with mechanical friction, thermo-electricity, photoelectricity, piezoelectricity, electrochemistry and electromagnetic induction being the chief forms of primary energy capable of producing electricity. Of these, the only significant source of commercial electrical power has been the mechanical actions of electric generators, and for mobile electric power the chemical action of batteries has been important. Usable motion has resulted from the interactions between the input of electrical energy and the magnetic and/or electromagnetic fields of force (electric motors) and heat or light as a result of input of electrical current through conventional mechanical systems, heaters, lightbulbs, etc.

All of the prior art systems are designed accordingly to rigid mathematical laws taught both in physics and electrical engineering which coincide with the hypothesis rigidly accepted by the industrial and scientific communities concerning the Second Law of Thermodynamics (1850).

From the foregoing generally accepted hypothesis it has also been generally accepted and rigidly taught in physics and electrical engineering that the electric current flowing in a closed circuit from a battery, electric generator, etc.

is used up in the mechanical device being operated by this flow of electric current, and that all such electric current producing systems would only put out at most work equal to the work initially put into the system, or in accordance with generally accepted laws stating that a particular electrical generating system was only capable of a given output of energy and no more.

These beliefs have till this date still remained rigid in both the industrial and scientific communities in spite of proof of Einstein's equation $E=mC^2$ Nuclear reactors convert matter into usable electromagnetic energy in the form of heat, which converts water into steam to turn conventional turbines for production of electric current by conventional electrical generating means. This system is extremely inefficient using less than 1% of the energy of the atom and producing a deluge of contaminated materials which has caused a serious problem as to safe disposal.

Additionally, the basic electrical generators is use throughout the world today utilise the principle of causing relative movement between an electrical conductor (for example a rotor) and a magnetic field produced by a magnet or an electromagnet (for example a stator), all using the generally accepted hypothesis that the greater the relative speed or movement between the two are concerned and the more normal or perpendicular the relative movement of the conductive material to the lines of force of the electromagnetic field, the greater will be the efficiency of the prior art electrical generator. Additionally, all of the prior art systems are based on the generally accepted hypothesis that the greater the electrical conductivity of the material being moved through the field, the more efficient will be the electrical generation.

From the foregoing generally accepted hypotheses, it also has been generally accepted that there should always be movement between, for example, the rotor and stator elements, and that only generally accepted electrical conductors, that is materials with high electrical conductivity, will effectively serve in an electrical generation system.

However, in one of the systems (**Fig.3**) of the present invention, electrical generation can occur with relatively static elements and with materials that are not generally considered to be of high electrical conductivity, although, of course, the present invention likewise can utilise relatively moving elements as well as materials of generally accepted high electrical conductivity, if so desired, as occurs in the systems of the present invention illustrated in **Fig.5** and **Fig.6**.

The prior art has failed to understand certain physical aspects of matter and the makeup of electromagnetic fields, which failure is corrected by the present invention.

BRIEF DESCRIPTION OF DRAWINGS

For a further understanding of the nature and objects of the present invention, reference should be had to the following detailed description, taken in conjunction with the accompanying drawings, in which like parts are given like reference numerals and wherein:

Fig.5 and **Fig.6** are schematic views in generalised, representational form of third and fourth embodiments of a combined electrical generator and motor utilising a static, relatively large coil energised by a relatively low current driving a rotatable magnet, wherein in the embodiment of **Fig.5** the rotatable magnet is positioned along side of the coil and in the embodiment of **Fig.6** the rotatable magnet is positioned within the open core of the coil.

DETAILED DESCRIPTION OF-PREFERRED EMBODIMENTS:

Basic Principles and Guidelines

In accordance with the principles of the present invention and as generally illustrated in **Fig.3**, an electromagnetic field **10** comprises flows of quanta or particles **20**, **30** of electrical energy flowing from each of the poles **21**, **31** of a magnet (or electromagnet) **40** to the other pole, following the "lines of force" **11** of the electromagnetic field. These particles **20**, **30**, believed to be travelling at the speed of light, are always coming out of one end **21**, **31**, respectively, of the magnet **40** and going into the other pole **31**, **21**, respectively, flowing from a relatively high energy source to a low energy source.

These particles **20**, **30** are, it is believed, negative and positive charges and have a spin producing a gyroscopic motion and follow the mechanical laws of gyroscopic action.

The mass of each of the particles **20**, **30** equals the energy of the particle divided by the speed of light squared. The peripheral speed of the gyroscopic spin of the particles is believed to be the speed of light.

For purposes of illustration only and as a matter of nomenclature, the positive charge particle **20** is going in one direction ('-'N" to "S") with a clockwise spin, and the negative charge particle **30** is going in the opposite direction with a counter-clockwise spin. Of course, if a particle such as **20** or **30** is flipped around one-hundred-and-eighty degrees, it becomes the opposite charge or type of particle.

The electromagnetic field **10** is thus the orderly flow of the positive and negative charges **20**, **30** moving at the speed of light from the north and south poles **21**, **31**, to the south and north poles **31**, **21**, respectively, and follow the paths of what is termed in the art as the "lines of force" **11** of the electromagnetic field **10**.

As is known from the laws of gyroscopes, a gyroscopic particle or body moves at right angles to the direction of an applied force. Therefore, when a force is applied to the electrical energy particles **20**, **30**, they will move at right angles to that force.

It should also be noted from known gyroscopic laws that the electrical energy particles **20**, **30**, when they move with their gyroscopic axis straight into an object, tend to knock that object straight, but, if that object hits the particles at an angle to the axis other than at zero or one-hundred-and-eighty degrees, the particles are moved off at an angle from the straight.

Additionally, it is noted that a magnetic field caused by a current flowing through a wire comes from negative and positive particles, such as **20**, **30**, with a net flow of such particles going in the same direction but with opposite spin.

In the system and method of the present invention, the foregoing principles serve as guidelines in the present invention.

Reference is further had to pages DD23 through DD27 of the Disclosure Document and to page 8, line 26 through page 11, line 23 of the prior application Serial number 25,907 and its Figures 7 - 10.

From the foregoing disclosures, many different devices, structures, and methods are possible to embody the principles and guidelines of the system of the present invention, which will in general utilise a material or substance or structure to place a force at the proper angle to the gyroscopic particles **20**, **30** wherein the particles **20**, **30** follow a path or paths which do not cancel one another out, thereby producing electrical current at appropriate outputs for further use or for increasing available potential electrical energy for ultimate use.

-First Embodiment (**Fig.1**)

One possible, exemplary embodiment using the principles of the system of the present invention is schematically shown in the generalised illustration of **Fig.1**.

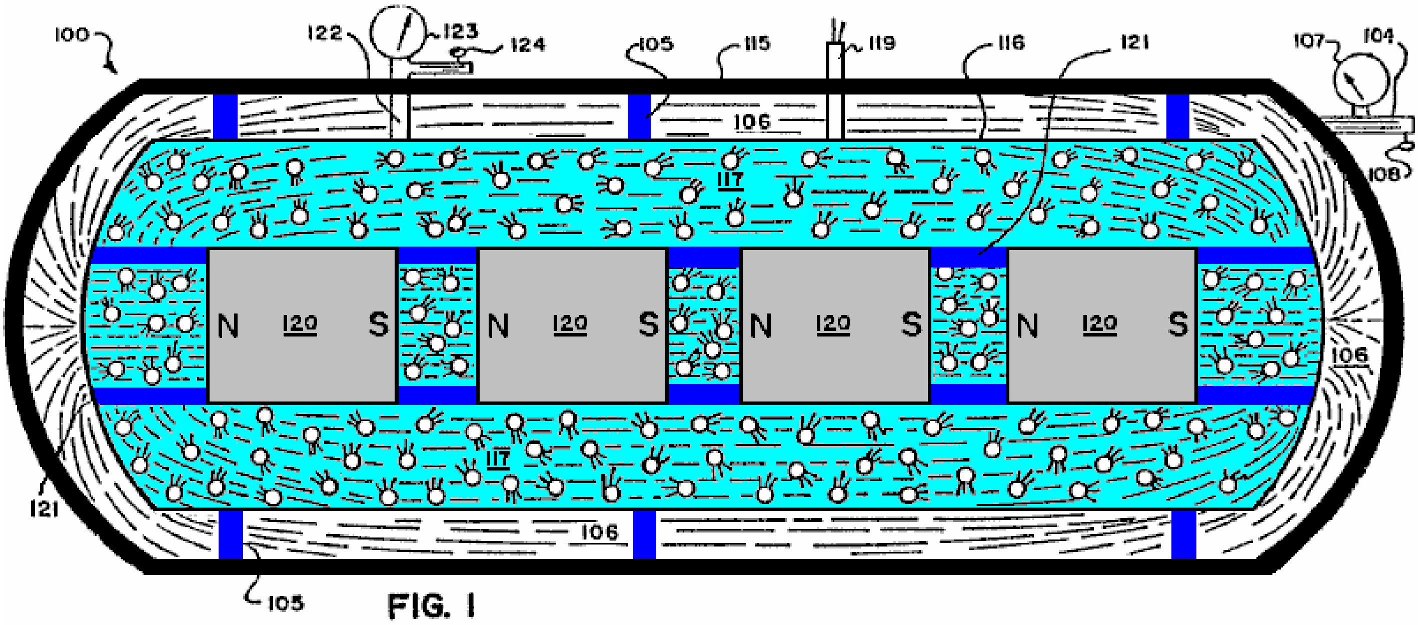

FIG. 1

As illustrated in **Fig.1**, there is provided an electrical current generator **100** comprising an outer keeper housing **115** and an inner, pressure containing, closed housing **116** supported therein by insulating supports **105**. A vacuum exists in the area **106** between the two housings **115**, **116**, which vacuum is regulated and induced by means of the vacuum line **104** with its gauge **107** and its control valve **108**. The outer housing **115** acts as a keeper for magnetic fields of force, and can be made for example of soft iron, while the vacuum in area **106** prevents the leakage or discharge of static electrical charges which might build up on the exterior of the inner housing **116**.

A gas or gas-liquid mixture **117** which may also include solid particles such as for example lead or brass filings, is included within the inner housing **116** surrounding a series of aligned magnets **120** carried by insulating braces or supports **121** and producing a high, combined electromagnetic field. The magnets **120**, which can for example be cryogenic magnets, have their "north" and "south" poles aligned (as illustrated by the "**Ns**" and "**Ss**") so that their magnetic fields reinforce one another.

The level of the gas or gas-liquid mixture **117** in the housing **116** is regulated by means of the line **122** with its gauge **123** and control valve **124**. Electric current output wires **119** are provided and extend down to electrically connect with a wire pick-up system **118** (shown in close-up in **Fig.2**), which can be for example in the form of very small wires forming a closely spaced network or mesh or of a porous conducting metal body or sheet, located in and extended throughout the fluid **117** in the housing **116**.

It is noted that a thimbleful of gas contains a fantastically large number of extremely tiny bodies which are in continuous, random motion moving at extremely high speeds. Hence, the fluid **117** continuously applies a force to the gyroscopic particles (analogous to particles **20**, **30** of **Fig.3**) moving at the speed of light ' in the high electromagnetic field (produced by the magnets **120**) as they continuously collide with each other, which results in the fluid **117** becoming electrically charged. The charged fluid **117** discharges its electrical charge to the pick-up wire network **118** positioned in the fluid, and the electric current so produced and generated is taken off for use via the electrical output wires **119**.

As an alternative to having internally contained magnets **120**, the electromagnetic field needed in the fluid **117** could be produced by a source located outside of the confines of the fluid **117** as long as a significant field was produced within the fluid **117**.

-Second Embodiment (Fig.3)

A further exemplary, generalised embodiment utilising the principles of the system of the present invention is shown in schematic form in **Fig.3**.

The electrical current generator **200** of **Fig.3** comprises an extended member **201** of a special material having its atoms especially aligned to produce electric current when positioned in an electromagnetic field but which does not on its own exhibit any substantial magnetic field outside of its boundary surfaces but substantially contains the field within itself. This is in contrast to "magnetic" materials which likewise have atom alignment but which also exhibit or produce a substantial magnetic field in the area surrounding it.

The generator **200** further comprises for example two magnets **202**, **203**, with their north and south poles facing each other, with the member **201** positioned between them, and with the three elements **201-203** held static with respect to each other. Because of the special nature of the material of the member **201** and its special atom alignment, it will produce a direct current through output line **204** as a result of the gyroscopic actions of the particles of the electromagnetic field **205** produced by the facing magnets **202**, **203**, on the especially aligned atoms in member **201**, which phenomenon occurs even when and even though the member **201** is completely static with respect to the magnets **212**, **203**.

However, it may be desirable in some applications to allow or produce some relative movement between the generator elements **201-203**. The output line **204** extends to an appropriate "load" **206** for using the electrical current generated by the generator **200**. A return line **207** completes the circuit back to the member **201**.

Based on experiments to date, it is believed that brass and lead are materials which can have their atoms especially aligned to interact with the gyroscopic particles (analogous to particles 20, 30) flowing between the magnets 202, 203 and will substantially contain within their surface boundaries the magnetic field produced by the aligned atoms or molecules.

With respect to producing the proper material with atom alignment for the member **201**, it is noted that most materials seem to align their atoms in random directions when formed by conventional methods of production. However, it can be observed that certain materials can be made magnetic by putting the material in an electromagnetic field while cooling from a temperature of around a thousand degrees Centigrade. The magnetism is the result of atom alignment of the material in a given direction (see pages DD19 through DD21 of the Disclosure Document). All materials are affected so as to align parallel or across lines of force when in a powerful electromagnetic-field. Accordingly, if a material while being formed is cooled in an extremely powerful electromagnetic field, the atoms of the material will take a particular alignment. The atom alignment direction could be varied depending on whether the electromagnetic field was aligned with the material or at a ninety degree angle to the material. This would result in the atoms of a material having their particular electromagnetic spin direction primarily along the same axis.

However, merely having atom alignment is not sufficient. Additionally the material for the invention should be such that it exhibits very little if any magnetic field in the area surrounding it. Thus it should be noted that the exterior electromagnetic field that occurs from the atom alignment of the conventional magnet is not duplicated in the material of the invention, because the electromagnetic energy resulting from atom alignment in the material of the invention will be primarily contained within the boundaries of the material It is believed that lead, made superconductive by immersion in a bath of for example liquid helium, is such a special material and could for example serve as the material for member **201**.

This then results in having a material which would place a force at the proper angle on the gyroscopic type particles moving in the electromagnetic field so as to cause an EMF to be produced even when the material was sitting still. (See also first paragraph of page DD23 and paragraphs four, A through E, of page DDl9 of the Disclosure Document).

It is believed that high, contained pressures, as well as other methods, can also probably produce atom alignment as the atoms of a conductor or any material will react to sufficient external force. (See first paragraph of page DD35 of the Disclosure Document). This possibility is also indicated by the fact that hard knocks or impacts will demagnetise a magnet.

The proper procedure of material production in achieving atom alignment with internally contained fields of force will cause the controlled release of electrical energy in electromagnetic fields of force when the material of the invention is placed in the lines of force of the electromagnetic field.

-Third and Fourth Embodiments (Fig.5 and Fig.6)

A. Related Principles

1. Numerous scientific tests and experiments made by the inventor indicate that the magnetic field resulting from an electrical current flowing through a conductor is the result of atom alignment within that conductor at an extremely high speed with an ability to reverse atom alignment just as rapidly without the magnetic hysteresis associated with conventional materials considered "magnetic." Prior to this time it has been believed and taught by the scientific community that the magnetic field associated with an electric current carrying conductor was the result of the electric current itself and not of the conductor material, for example copper, which was considered to be "nonmagnetic." Even the inventor was influenced and mislead by these teachings and attempted to mechanically explain and justify the prior teachings, as is seen on page DD-27 of the Disclosure Document which is an important part of this patent application.

However, as taught in the present invention, what mechanically happens is that the gyroscopic particles making up the electric current moving in a conductor interact with the electromagnetic makeup of the atoms of the conductor, causing them to align extremely rapidly, thereby then releasing some of their electromagnetic make-up in the form of a magnetic field exactly as explained in great detail for conventional magnetic materials in the Disclosure Document.

This is easily proven and understood by taking for example, a size 14-gauge conductor one foot long, winding it into a coil and connecting the coil to a meter and a 1.5 volt battery. The total current registered on the meter will be 1.5 amps and the strength of the magnetic field created from the short conductor will be extremely small. Next, the same type of test is run again but with the length of the conductor increased to for example two thousand feet, but still in a coil. The total current registered on the meter will now be considerably less, but the strength of the magnetic field given off from the conductor will now be extremely large!

This shows that the magnetic field is not from the electric current flow, but is the result of the interactions of the gyroscopic particles which make up the electric current interacting with the atoms of the conductor! This causes the gyroscopic particles of the electric current not to be able to make the circuit back to the battery so quickly, and therefore the meter shows less current used.

The magnetic field is the result of the atom alignment of the conductor. The more atoms in a conductor (up to a point), the stronger the magnetic field produced from a given amount of electric current input. Again, this is proven by changing the diameter of the conducting wires, and, with the lengths being the same, the strongest magnetic field will result from the conductor with the largest diameter. The reason for this is that there are more conducting atoms to interact with the gyroscopic particles of the electric current moving through the conductor, which results in a greater number of conducting atoms being aligned, thereby then releasing some of their electromagnetic make-up, exactly as has been explained in great detail in the Disclosure Document as being possible for all matter.

If the magnetic field produced was strictly based on the amount of current going through a conductor, as taught in the prior art, then the strongest magnetic field would result when current went through a large diameter and short length conductor, because the current flow through the entire circuit is greatest at that time. However, experiments prove that the shorter a conductor is made, the greater the current flow through the entire circuit and the less strength of the magnetic field surrounding that conductor. The longer that same conductor is made (up to a point), the greater the magnetic field surrounding the total mass of the conductor and the less current that makes the complete circuit of the entire system. Reason: more atoms!

2. Numerous scientific tests and experiments made by the inventor also indicate that the magnetic field created when an electric current moves in a conductor does not use up measurable energy when performing obvious or non-obvious work, force or power. This is true no matter how strong or how immense the power of the motor or electromagnets is.

Reason: the magnetic field coming from the conductor is the result of extremely quick atom alignment within that conductor. Therefore the energy in the magnetic field is the energy that makes up the atoms of the conductor! This energy is literally Einstein's equation of E=MC2, and therefore the energy is believed to be moving at the speed of light.

This energy use cannot be measured by today's measuring instruments. This has been explained in great detail in the
Disclosure Document and is believed to be true of all matter!

3. The same is true for the electric current that comes from a conventional battery. The electromagnetic energy coming from the battery is the energy that makes up the atoms of the material of the battery! Again this energy use is not measurable by today's measuring instruments. Electric meters of all types are simply mechanical devices which measure the amount of electric current that comes into that instrument. They do not measure the amount of mass that has been converted into electromagnetic energy.

Present teachings in science state that the electric energy flowing from a battery is used up in the device operated by that flow of electric current. This is not true at all! The electromagnetic energy released from the atom make-up of a battery has a relatively infinite capacity to do obvious work, force, or power.

This is easily proven even with a small motor and a 1.5 volt battery. With a battery connected to motor to operate it and with a meter to take readings, the motor is then physically stopped from turning by physically holding or restraining the shaft. At that moment the motor is performing no obvious work, force or power, but the meter will register a greater flow of current. The magnets of the motor can be taken out and the reading will still be the same. If the electric current was being used to operate the motor, the meter would register more current when the motor was running.

The electric current not only will operate the motor but, once it flows through the complete circuit back to the battery, it also does additional work based on Faraday's Laws of Electrolysis within the battery itself. What has happened is that the electromagnetic energy released from the atoms of the material of the battery once they have completed the circuit, then take a "short cut" and move large pieces of the mass of one material of the battery over to the other material of the battery. The inventor has stated and shown throughout the Disclosure Document that the effect of gravity was the non-obvious effect of electromagnetic energy. Once the materials of the battery have combined, the extreme desire for the two materials to merge is physically reduced. These materials will attempt this merger anyway possible and, if the electric current initially released from a battery is not allowed by mechanical means to complete the circuit back within itself, the electromagnetic energy then in the mechanical means will perpetually (in a relative, theoretical sense) perform obvious work, force or power. The reason: the force which initiated this flow of current (electromagnetic make-up of atoms of material) is constant, similar to hydraulic pressure, with the noticeable exception that it is moving it is believed at the speed of light and will interact with the electromagnetic make-up of the atoms of other materials, causing them to release some of their electromagnetic make-up in the form of a magnetic field. This then multiples the capacity for doing obvious or non-obvious work, force or power, which can then react with another conducting coil or with the electromagnetic energy within the magnetic field of a conventional magnet and multiply this effect even further, and on and on and on for a relatively unlimited source of energy.

The same is true in not letting the current get back to a conventional generator. If a mechanical means is set up so that the electric current is "trapped," without completing a circuit, the gyroscopic particles of the current have a capacity for continuous work without increasing the power input into the generator system. However, if the circuit is complete and the electric current moving in the system does absolutely no obvious work, power or force, the gyroscopic particles making up the current on getting back to the generator will then increase the need for more power input into the system. Reason: the opposing effect of magnetic fields as defined in Lentz’s Law. This law is simply an observation of this effect, which before now has never been fully understood.

4. Numerous scientific tests and experiments made by the inventor also indicate that there is a correlation between the electromagnetic spin orientation of the atoms of non-conductors, semi-conductors, and conductors, and the varying results achieved with an electric current in attempting to move through these materials, or when moving these materials through a magnetic field attempting to induce electric current. The property of resistance to electric current movement is generally speaking the same type factor already explained above for electric current producing a magnetic field when moving in a conductor.

The gyroscopic particles in a moving electric current interact with the atoms of the material through which the current is moving. Each atom can efficiently only interact with sun exact maximum amount of electric current, and, if exceeded, there is an interruption of orderly movement. Then the angle of release of the gyroscopic particles from the atoms are such that the electromagnetic release from those atoms are in the form of heat, exactly as explained in great detail in the Disclosure Document. This effect is easily observed by the fact that resistance decreases relative to an increase of the cross-section of the material. Reason: simply, more atoms within that given area, and, for a fixed input of electric current, there are more atoms to receive and interact efficiently with the gyroparticles making up the electric current.

Again the same is true for resistors designed for deliberately producing heat. Such resistors are not materials which are considered good conductors of electric current. It is stated and shown in great detail in the Disclosure Document that the electromagnetic spin orientation of the atoms of a non-conductor are different from that of conductor atoms, and therefore different results will occur from the same inputs of electromagnetic energy.

This is easily seen by the fact that, in a resistor, for a given amount of electric current input, the heat release increases as the diameter increases. What that means is that the property of resistance has decreased. On a conductor it is just the opposite. If the diameter is increased the resistance is decreased, but so is heat release. Again, this is an indication that the gyroparticles in the electric current movement interact with each atom of the material. This same effect shows up again in conventional electrical induction from a conductor interacting with a magnetic field. Experiments by the inventor have indicated that the property of conventional induction is the result of the same property of resistance.

If one increases the diameter of a conductor, lengths staying the same, one decreases the amount of electric current produced relative to the total number of atoms within the conductors under consideration. Or, if one takes a given number of wires of the same diameter and length, and moves a magnet across them, the current produced will be considerably less, than if one takes the same diameter wire, but only one wire, and increases its length considerably and then forms it into a coil forming the same number of wires on any one side and then moves the same magnet across only one side of that coil, the electric current generated will then be considerably greater. Reason: the property of resistance. This is the mechanical effect within the gyroscopic electromagnetic make-up and orientation of the atoms of all materials which have the mechanical ability to perform a given task efficiently up to a point concerning input of additional electromagnetic energy and then mechanically causes varying results once this threshold is exceeded.

This and all the other thoughts and innovations in this and the previous disclosures of the previous applications and the Disclosure Document previously put forth show that there are many different mechanical ways to release a relatively unlimited source of energy from electromagnetic energy which makes up all matter and which results from this invention.

B. Working Prototypes

Fig.5 and **Fig.6** illustrate rough, working prototypes of this aspect of the invention. These embodiments are only relatively inefficient prototypes built by hand for the purpose of demonstrating the invention. It should be self-evident that the prototypes, by various mechanical means and designs, can easily be made extremely efficient and the illustrated embodiments are being presented only for general, representational purposes.

As is illustrated in **Fig.5**, there is provided a combined electrical current generator and an electromagnetic motor comprising a rotatably mounted, permanent magnet **200**, a battery **201**, brushes and commutator **202**, bearings **203** and power, mounting shaft **204**, and a first, primary, magnetic producing coil **205** and a second, secondary electric producing coil **206**. The two coils **205**, **206** are juxtaposed together in parallel disposition with concurrent core centre-lines, with the magnet 200 positioned alongside of coil **205** at or near its core centre-line with the rotational axis of the shaft 204 positioned orthogonally to the centre-line.

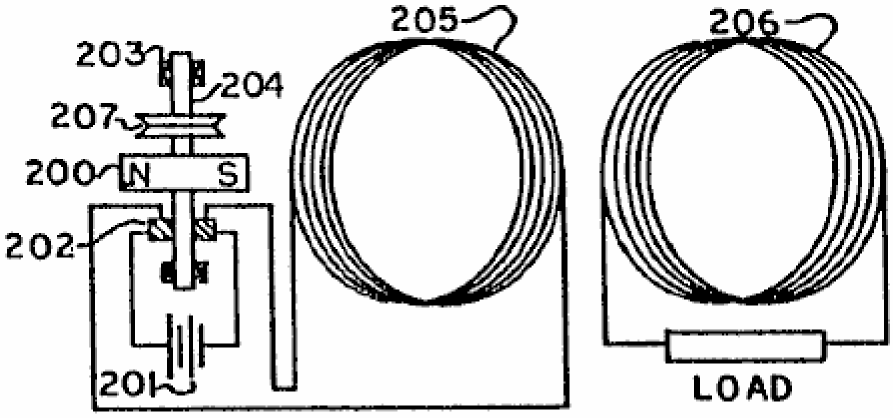

FIG 5

In the prototypes a very small battery **201**, for example, size "N", of 1.5 volts is used. When the circuit is completed, the battery **201** converts an immeasurable amount of its mass into electrical current (gyroscopic particles moving at the speed of light) which goes out through the communicator and brushes **202**, and then enters magnetic producing conductor coil **205** made, for example, from insulated 14-gauge or 15-gauge copper wire, with the total weight of the coil **205** being for example seventy to ninety pounds. This causes the atoms of coil **205** to align extremely fast then releasing some of their electromagnetic make-up (gyroscopic particles) in the form of a magnetic field. This field then interacts with the gyroscopic particles making up the magnetic field coming from the atoms of the material of the permanent magnet **200**.

This causes magnet 200 to attempt to align its magnetic field movement with the magnetic field movement coming from the atoms of coil 205, resulting in rotation of magnet 200 and the shaft 204 to which it is attached. This then changes the position of the commutator and brushes 202 relative to each other's initial positions, which then causes the electric current coming from battery 201 to be going in the opposite direction into coil 205, causing the atoms of coil 205 to extremely quickly reverse their alignment and the polarity of their magnetic field which they are emitting. The reversed field then interacts again with the magnetic field of permanent magnet **200**, causing it to further rotate.

This process is then continuously repeated, producing continuous rotation of the shaft **204** which can be used as a source of motive power in many different ways. A power belt wheel **207** for example using a continuous "V" belt is illustrated as a general representation of this motive power source for producing useful, obvious work. In a prototype test run with a small 1.5 volt, type "N" battery, the shaft **204** and the magnet **200** - rotated at a high speed for approximately twelve hours before running down. By improving the particular design features of the prototype and by using longer lasting batteries, the rotation time of the shaft **204** can be greatly increased to a theoretical point approaching "perpetual" for all practical purposes. At the same time the alternating magnetic field produced by the coil **205** induces into coil **206** electrical induction, which then causes coil **206** to produce an alternating current across its "load," which current can be made to exceed the conventional output of the battery **201**. The battery source **201** can be replaced when needed.

It is very important to understand that, the longer the length of the conducting wire in coil **205**, the stronger will be the magnetic field produced and the less electric current that will complete the circuit and get back into the battery and destroy the mechanical source of the electrical current. This effect can be increased further by increasing the diameter of the conducting wire in coil **205** and then greatly increasing its length still further in the coil.

Reason: The gyroscopic particles making up the electric current interact with the atoms of coil **205**. The more atoms in coil **205**, relative to it's length, the longer it takes the gyroparticles of the electric current to influence them and exit from the other end of the coil. It is then easily seen that if the direction of the current flowing into coil **205** is then reversed, this then further increases the lag time. Reason: The gyroscopic particles have inertia and are believed to be moving at the speed of light and they are interacting with the gyroscopic particles making up the atoms of the conducting coil **205**. These atoms also have inertia, and when the direction of current in coil **205** is reversed, the incoming current then collides with the current already in coil **205** going in the opposite direction.

This causes a brief hesitation during the time the current already in the coil is being forced to reverse its direction, thereby then reversing the direction of the atoms within coil **205** which have already been influenced to become aligned. This causes a constant force throughout the circuit, but does not allow very much current to get back into the battery **201** to destroy the mechanical means which initiated the release of electric current in the first place.

Therefore, it should be further understood that, the faster the current direction reverses into the coil **205**, the more efficiently the matter of battery **201** is converted into 2 pure electrical energy ($E=MC^2$), without destruction of the mechanical situation that initiates the electrical current release.

It is also important to understand that, the stronger the magnetic field coming from the mass of magnet **200**, the greater will be its rotational speed. Additionally, the greater the magnetic field coming from the mass of coil **205**, the greater will be the rotational speed of magnet **200**, and, up to a point, the greater the electric current input from battery **201**, the greater the rotational speed of magnet **200**.

Reason: the greater the electric current flow into coil **205**, the greater will be the percentage of the atoms making up coil **205** that are aligned. This probably has the same relationship as does achieving atom alignment in conventional magnetic materials. Once complete atom alignment is reached in coil **205**, no amount of current will cause those atoms to increase the strength of the magnetic field emitting from those atoms.

Therefore, it should be clear that, for a given input of electric current from battery **201**, the most efficient design is one in which the most atoms of coil **205** are influenced to atom alignment by that given electric current, which means increasing the diameter and the length of the conducting wire of coil **205** to the point that the strength of the magnetic field produced is sufficient to cause rotation of the magnet **200** to a speed that allows none or at least very little of the electric current which initially comes from the battery **201** to complete the circuit and get back into battery **201** and destroy or reduce the mechanical effect which induced the conversion of the matter of battery **201** in electric current in the first place. Again this desired effect can be increased by increasing the strength of the magnetic field given off by the atoms of the permanent magnet **200**.

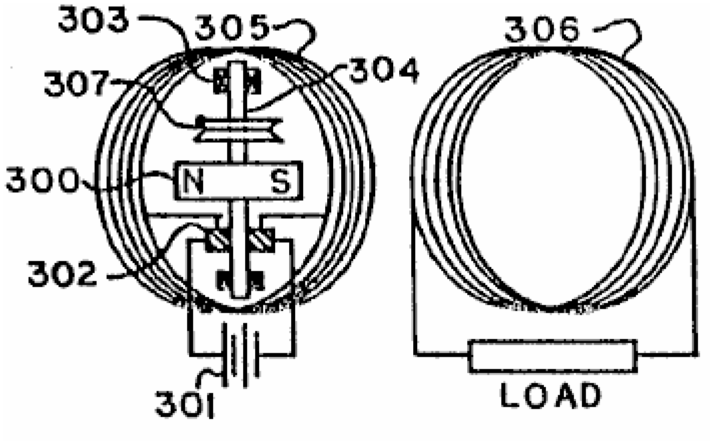

FIG 6

In the second prototype embodiment of **Fig.6**, the structure and operation of the prototype is substantially identical to that of **Fig.5** with the major exception being that the magnet **300**/shaft **304** elements (and related sub-elements **302**, **303** and **307**) are positioned inside of and within the core of the primary coil **305**, as compared to the placement of the magnet **200**/shaft **204** elements next to and along side of the coil **205** of **Fig.5**. Therefore, for brevity, a detailed description of the elements of **Fig.6** will not be repeated, but it is noted that the corresponding and analogous elements and sub-elements are similarly numbered in **Fig.5** and **Fig.6**.

It is also important to again stress the fact that the prototype designs shown are presented simply to prove the correctness of the invention, and it should be clear that the invention can be made extremely more efficient by utilising all of the magnetic field produced by coil **205** and designing the magnet **200** of a shape and strength that efficiently interacts with the majority of the magnetic fields from coil **205**. The illustrated prototypes is relatively highly inefficient in this regard, but even so, the results of the invention itself greatly exceed the prior art as to use of electric current from whatever source and interaction with an electric motor or whatever work was conventionally performed.

The applicant feels it is very important to again stress, in building many varying designs of this invention, consideration must be given to the fact that the Energy in the field of force of any type magnet is the Energy that makes up the Atoms of the material from which it comes! This Energy is a real Entity with, it is believed, a gyroscopic action. It is literally Einstein's Equation of $E=MC^2$ and it is believed that this Energy moves at the speed of light and makes up all Matter. And that this Energy has a constant pressure effect back to the Atoms of the material from which it came, similar to hydraulic pressure. This effect is additionally more fully understood by stating the following results obtained from experimentation by the applicant in the process of this invention.

a) When the system is initially attached to a 1.5 volt size N Battery **201** or **301** and the magnet **200** or **300** and related rotation entities are placed close to or in the centre of coil **205** or **305**, the following results are observed:

If the electric current produced in coil **206** (**306**) is then fed back into coil **205** (**305**) in accordance with proper polarity, the rotation speed of magnet **200** or **300** will then accelerate. If fed back into coil **205** (**305**) in wrong polarity, the rotation speed of magnet **200** (**300**) will slow down.

This proves that the total force from coil **205** (**305**) interacting with the magnet **200** (**300**) is greater when the electrical energy from coil **206**(**306**) is fed back into coil **205** (**305**), then when only the initial electric energy from battery **201** (**301**) is fed into coil **205** (**305**)! When two or three batteries are electrically connected together in series, so as to create for example three or four and a half volts of electrical input, this effect is multiplied. Remember, up to a point, the greater the electrical input, the greater the percentage of atom alignment within coil **205** (**305**).

This further proves that the electric current produced in coil **206** (**306**) is a result of the gyroscopic particles of Energy released from the magnetic fields which came from the Electromagnetic make-up of the atoms of coil **205** (**305**), and is not part of the initial Electrical Energy released from the atoms making up the materials of battery **201** (**301**)! The coil **206** (**306**) can be taken out of the system, or its electrical current fed away from the system, and the rotational speed of the magnet **200** (**300**) will not observably change. However, the rotational speed of magnet **200** (**300**) will noticeably change when the electric current from coil **206** (**306**) is fed back into coil **205** (**305**)!

Now a different result:

b) When the electric current from battery **201** (**301**) becomes weaker to the point that the magnetic field coming from coil **205** (**305**) has weakened and shrunk allowing the magnetic field of the rotating magnet **200** (**300**) to expand and then noticeably induce electric current into coil **206** (**306**) and into coil **205** (**305**), then reverse results are observed. When the magnetic field from the coil **205** (**305**) is large, then the magnetic field from magnet **200** (**300**) is retained! If coil **206** (**306**) is then short circuited, the rotation of magnet **200** (**300**) will noticeably slow down.

If electric current from coil **206** (**306**) is fed back into coil **205** (**305**) in wrong polarity, the rotation of the magnet **200** (**300**) will stop. If fed back into coil **205** (**305**) in correct polarity, the rotation of the magnet **200** (**300**) will slow down. At that point, the rotation of the magnet **200** (**300**) will not accelerate, no matter how connected!
